When at *Chatsworth* last August I was astounded at the magnificent specimens of *Chrysanthemums*. I inquired what was the treatment and how they were potted. "As firmly as possible," was the reply. These were the finest specimens of *Chrysanthemums* many others besides myself had seen; some of them were 4 feet high and as much in diameter, though never stopped. With this treatment many growers would not agree, though when seeing a large quantity potted at one of our leading nurseries I asked the reason they were potted so firmly, and I was told it was to keep them short-jointed. I remember asking Mr. Joseph Speed, whom many of your old readers will recollect, the nearest rule he could lay down for potting. His answer was, "According to the size of the roots." He said, though there are many exceptions, the finer the roots the firmer the potting required—that is to say, plants with very fine roots need very firm potting; those with medium-size roots require medium potting; and those with large roots light potting. I have been told by one who ranks among the first of British gardeners that in ninety cases out of a hundred he pots firmly, and his plants are among some of the finest in the country. Now as this is a subject in which many are interested perhaps some of your practical readers will state their experience.—E. J. SPEED.

EUPATORIUM PURPUREUM.—One of the most distinct and imposing plants in my herbaceous collection at the present time is the above-mentioned Composite. The specimen, or rather clump, is about 6 feet high and equally as much in diameter, and each of the numerous stems terminates in a large corymb or panicle of small purplish-coloured capitula. It occupies a position at the back of a long border, and being situated at a bend is not only prominent but really ornamental, the stems being densely clothed

with leaves to the ground. Any ordinary garden soil seems to suit this species, which thrives admirably with me.—D., *Surrey*.

THE SCOTCH CHAMPION POTATO.

HAD this much-praised Potato proved to be really "disease-proof" I might have retained it as a last resort when other varieties failed, and for cross-breeding, in view of raising seedlings in which we might hope to combine freedom from disease with what I must venture to term the higher qualities of delicacy of flavour, mealiness, whiteness, and full plump eyes. Now we have plenty of varieties that, with the exception of the visionary freedom from disease, are known to possess not only all these good qualities, but the additional ones of haulm of medium vigour, and fitness of the tubers for table during eleven months of the year. With this indisputable fact before me am I to be considered open to rebuke for refusing to continue the culture of a variety in which most of these points of excellence are conspicuous by their absence? No doubt a keen sense of the existence of an urgent necessity for an immediate supply of seed of a Potato calculated to afford an abundant crop prompted the large orders which were given for this variety for Ireland last spring; but that was a matter quite beside the mark, and should have no weight in this discussion. Grown side by side with several other varieties it was compared with them and found wanting, just as White Rock and Redskin Flourball had been long ago.—EDWARD LUCKHURST.

THE NATIONAL FRUIT EXHIBITION, which opens at the Alexandra Palace on the 3rd inst. and continues for four days, is expected to be of considerable magnitude and excellence, as we are informed the entries are numerous. The schedule is a very liberal one, £15, £10, and £6 being offered for "twenty varieties of fruits," and £6, £4, and £2 for "ten varieties of fruit." This is not sufficiently explicit, and it will be well if no misunderstanding arises in these classes. If "kinds" of fruit are meant exhibitors ought to be made aware of it, and then there will be few competitors able to exhibit twenty kinds of fruit of their own growing. If twenty dishes are meant suitable for a dessert table, then it could be stated that black and white Grapes, green and scarlet-fleshed Melons, Queen and any other Pine, red and white Raspberries, and dark and light Plums, would (if so determined) be considered as distinct dishes, for facilitating competition. At present if six varieties of Grapes were included in a collection of twenty varieties of fruit, that collection could not be easily disqualified. Yet this can scarcely be what the managers mean. Greater precision in describing the classes is needed in many schedules, hence we allude to the subject now. The prizes in the Grape classes are good, and other fruits are well provided for in the schedule under notice.

— A CORRESPONDENT informs us that there is now flowering in the garden of Sir Henry Watson Parker, Stawell House, Richmond, a beautiful plant of the far-famed "SCOTCH TROPÆOLUM" (*T. speciosum*). It is quite established, and throws its slender growths covered with flowers for a considerable distance. Any person may see the plant on application to Mr. Bowell, the gardener.

— WE learn that the YORK FLORAL FETE proved a great financial success this year. The profits from the Exhibition in June amounted to the handsome sum of £255, thus increasing the balance to £1500 to the credit of the Committee. The prizes paid to exhibitors amounted to £476, and another very important item in the expenditure was £148 for music. From the profits above mentioned £157 10s. were devoted to the various York charities—an admirable use to make of a surplus. We are glad to find that the Committee are so well supported.

— THE stand of GLADIOLI exhibited by the Rev. H. H. D'Ombraín at the Crystal Palace Show, which was so generally admired, contained the following varieties—Madame Desportes, Meyerbeer, Baroness Burdett Coutts, Archduchess Marie Christina (to this a first-class certificate was awarded), Adolphe Brongniart, Lady Bridport (Kelway), Rev. H. H. D'Ombraín (Kelway), very fine; Leandre, Legouvé, De Mirbel, and two seedlings.

— WE are requested to remind intending competitors at the INTERNATIONAL POTATO EXHIBITION that the 14th inst. is the last day that entries can be made for Messrs. Suttons' valuable prizes for eighteen varieties of Potatoes, distinct, nine tubers of each, open to noblemen's and gentlemen's gardeners only. We also learn that Messrs. Sutton have arranged that their prizes shall be awarded by gentlemen's gardeners. All entries should be made to J. A. McKenzie, Esq., Tower Chambers, Moorgate, London, E.C.

— WE have received from Mr. Cuthbertson, Rothesay, a bloom of his new dark self PANSY, DAVID MALCOLM, for which three first-class certificates have been awarded. It is a handsome flower of medium size, perfectly circular, with smooth overlapping petals of great substance and a small orange eye with a halo of violet. The top petals are velvety black, the lower petal shading to rich purple. We think it deserves its honours. A spike of the new Snowflake Candytuft accompanying it, and which has also been certificated, is remarkable for its size and depth, and the purity of the flowers.

— WE learn that the twenty-fifth annual Exhibition of the ISLE OF THANET FLORAL AND HORTICULTURAL SOCIETY held last week was one of the best and most largely attended of the whole series. The excellent Committee—of whom Mr. G. E. Hannam, J.P., is Chairman; Mr. W. Manser, Vice-Chairman; and Messrs. C. D. Smith, Brook Terrace, Margate, and Mr. H. Austen, jun., Fairfield, St. Peter's, the indefatigable Secretaries—had spared no pains to make every provision for a successful show, offering some 450 prizes for competition in the different classes, and their exertions were admirably seconded by the exhibitors. The various exhibits were, as a whole, up to the average, the foliage plants being especially varied and excellent. Plants in bloom, of various descriptions, were in capital condition; but the best feature of the Show was the cut flowers—Roses, Dahlias, Asters, &c., being in large variety, and generally very fine. Mr. Cannell's collection (not for competition), was particularly noticeable. The fruit was of very varied quality, none of the Grapes being well-shaped, though large and heavy bunches were shown in good numbers. Of Potatoes there was an immense number, and the tubers throughout were very fine. In the plant classes Mr. Friend, Northdown (Mr. Miller, gardener), was remarkably successful. Mr. S. Herepath, Westwood Cottage (Mr. Jarman), Mr. E. F. Davis, St. Peter's Cottage (Mr. Johncock), also secured several prizes. In the cut flower classes Messrs. Kinmont & Kidd, Canterbury, and Mr. J. Bunyard, Ashford, were the premier exhibitors of Dahlias, Gladioli, and Roses; and Messrs. Jarman, Johncock, Clark, and Kimpton were amongst the most successful competitors in the principal classes for fruit.

— THE usual weekly Exhibition at the Alexandra Palace was on Saturday last devoted to DAHLIAS, which were contributed by Mr. C. Turner of Slough. Many hundreds of blooms were staged, representing all the different sections—viz., Show, Fancy, Bouquet, and Bedding varieties, and comprising many handsome novelties. They were arranged on stands down the centre of the great hall, and formed a very bright and satisfactory display.

— ON the rockery at Chiswick that beautiful and interesting plant, *ACÆNA MICROPHYLLA*, is now very attractive with its numerous heads of rosy-crimson spines and diminutive pinnate leaves. It is a species of very dwarf habit, being only a few inches high, and produces its small greenish flowers in close heads.

The calyx is furnished with spines each of an inch or more in length, and it is to the rich colour of these that the plant owes its chief attractions. The species is admirably adapted for a low position on a rockery, succeeding well in a compost of peat and loam, and is quite hardy. It is seen in some collections under the name of *A. novæ-zealandiæ*, a term that is by no means distinctive, as several species are also found in New Zealand, so that the name by which it is designated in Sir Joseph Hooker's "Flora of New Zealand,"—viz., *A. microphylla*, is much more appropriate.

— MR. W. ROBERTS writes as follows on the WEATHER AND THE CROPS IN CORNWALL—"We are having beautiful weather here at present, and things are looking well. Apples and Pears are short, but some other fruits are looking as well or better than they have for a long time past. Of Wheat, Oats, and Barley there is an abundant crop. Peaches are quite a failure."

— WE are requested to state that the *employés*—Nurseries & Seed Stores—of Messrs. JAMES CARTER & CO. met in a cricket match at Forest Hill on Saturday last, the result of the contest being to the advantage of the former. A very agreeable evening was afterwards spent in the neighbourhood by a hundred or more of Messrs. Carters' assistants.

— WE have received from Messrs. Edward Webb & Sons, Wordsley, Stourbridge, some blooms of ORANGE AFRICAN MARGOLDS grown in their trial grounds at the Kinver Seed Farms. The blooms are not large, but of excellent form, very compact, and rich in colour. They represent a good strain.

— A VERY fine hardy aquatic plant is *SAGITTARIA SAGITIFOLIA FLORE-PLENO*, which bears its large double pure white flowers in whorls on a scape 2 or more feet in height. The plant succeeds very well in a loamy soil, either in a pot plunged beneath the surface of the water in a shallow tank or planted out in a similar position. The variety is much more attractive than the well-known wild form, the flowers being very regular in outline and rather more than an inch in diameter.

— WE recently noticed in a small suburban garden a very tasteful combination of *TROPÆOLUM PEREGRINUM* AND SWEET PEAS. These were trained to a number of stakes at intervals of about a yard, so as to form a series of compact floral pillars; the bright yellow flowers of the *Tropæolum*, and the purple, crimson, and white blooms of the *Lathyrus* intermingled, producing a charming effect.

— A CORRESPONDENT obligingly sent us a report, which arrived too late for insertion last week, of the WHICKHAM FLORAL SOCIETY'S SHOW. The Exhibition was held in the rectory grounds at that town, by the permission of the Rev. H. B. Carr. Plants, flowers, fruit, and vegetables were well shown by Messrs. E. Adams, Swalwell; T. Battensby, Axwell Park; J. Lawson, Whickham; T. Lambert, W. Spoor; R. Gardner, Dunston; G. Smith, J. G. Ismay, W. Mowbray, J. Caulthorn, and T. Harrison. A variety of amusements was provided, and the Exhibition was well attended by visitors, the receipts covering all expenses and leaving a balance to the credit of the Society. All the arrangements appear to have been satisfactory and creditable to the Secretaries, Messrs. R. Burns and Thomas Lambert.

— A CORRESPONDENT of a daily contemporary writes:—"During my entire journey from TEHERAN, PERSIA, TO SHAHR-ROOD I have not seen a single Orange, Olive, or Palm tree. The Pomegranate and Fig and black and white Mulberry flourish luxuriantly. In all reason it is certainly hot enough for Olives; and one would imagine that a people so fond of putting greasy matter into their pilaff as the Persians would have made some effort to secure a supply of oil. The absence of the Orange, too, astonishes me. One sees it growing and ripening thoroughly in far more northerly latitudes. As for the Palm, as a proof that it

would grow here, there is one at present in the gardens of a deserted palace on the Caspian shore, which is said to date from the time of Shah Abbas the Great. There is a tradition, too, that the ground between Asterabad and the Atterck was once one immense Palm grove. Yet this tree of the East *par excellence*, and which plays so important a part in the existence of many oriental nations, is here nowhere to be seen. The figure of the camel with his stalking gait and outstretched swaying neck seems out of place without a Palm tree in the background."

— MESSRS. JONES & SON state that the prizes for Phloxes were not awarded exactly as represented in our report of the Shrewsbury Show, but that they received the premier prize for those flowers.

RED SPIDER IN VINERIES.

SOME remarks have been published relative to this pest, and modes of prevention. One writer neither finds it necessary to syringe his Vines nor damp the vineries; another finds it requisite to employ more or less moisture in the houses. The differences can only be reconciled by locality. I have lived in the west of England and rarely saw red spider, but I am now in a "red spider district." In the former locality I could, so far as relates to atmospheric moisture, safely leave that question pretty well to Nature, but I cannot do so now.

I have now a rather striking proof of the value of damping the paths and walls of vineries occasionally with guano water, in keeping the pest at bay. The late dry and hot weather has caused red spider to increase rapidly outdoors. Kidney Beans are covered with it, and Vines on walls are attacked. Under glass I have not seen one insect, but through a broken square near the top of the roof of a vinery a lateral has found its way, and the young foliage of this lateral is furnishing food for numbers of the insect. This appears to me tolerably conclusive proof that, in my case at least, the moisture employed in the house has been beneficial, and the circumstance may be worth mentioning in the Journal, to which so many gardeners and amateurs turn for plain practical information.—MID-SURREY.

AUSTRALIAN FOREST TREES.

A TOWERING giant indeed is the *Wellingtonia* of California. But the Gum Tree of Australia—mounting over 400 feet, able if placed beside St. Paul's Cathedral to throw a shadow over it, and having timber enough to construct a big ship out of a single stem—is the vegetable monarch of earth. Few things more strike the young Gum-sucker on a visit to the land of his forefathers as the diminutive size of our forest trees. He smiles when he hears praises of mighty Oaks. The wonder of the Kangaroo country is not confined to the size of its timber, but extends to the variety of species and the economical uses to which they could be devoted.

The first tree brought into requisition by the early Sydney settlers was a species of Palm, the stem of which was easily used in building. The curled top served for Cabbage, giving the plant the name of Cabbage Palm, while the fibre made the celebrated Cabbage tree hats of Bushmen. In Adelaide the Reed beds supplied the first colonists with framework for dwellings. In Melbourne the Stringybark gave a covering for roofs and slabs for hut sides. As progress went on Pine forests and Cedar belts were invaded for more convenient and valuable woods. The furniture makers, not content with these, sought more rare and beautiful material in Australian shades. Coopers and veneerers, wheelwrights and gunmakers, carpenters and shipwrights, tanners and dyers, with other tradesmen looked for special timbers. The chemist had his objects of search, and the druggist added precious medicines from colonial forests.

Queensland is favoured even in favoured Australia with a variety of valuable woods. In a work on the "Resources of Queensland" it is said that "The most useful trees for building purposes are the Stringybark, the Gums, Cedars, Pines, Cypress Pine, Kauri Pine, Red Mahogany, Yellow-wood, Citron-scented Gum, Ash, Beech, Brigalow, Ironbark, Box, Blackbutt, Bloodred, &c. Those for veneering are Forest Oak or Beefwood, Red Cedar, Sweet Plum, Satinwood, Sandalwood, and Ebony. For staves, Silky Oak, Tulipwood, Stavewood, and Boyum-boyum are used; for flooring, Stringybark and White Pine; for wheelwright's work, Sour Plum, Blue Gum, and Apple tree; for turnery, Scrub Rosewood; for gunstocks, a species of Acacia; for dyeing, Cockspur Thorn; for shipbuilding, Gums and White Mangrove; for bark-tanning, several kinds of Wattle, Ironwood, and Mangrove; for hoops,

Hoopwood ; for medicinal bark, Crab Tree, Fever Tree, and Cascarilla ; for cabinetwork, Yellow-wood, Queensland Nut, native Lime, Tulipwood, Broad-leaved Cherry tree, Scrub Lignum Vitæ, Weeping Myall, Ironwood, and Mountain Cherry. But the Apple, Cherry, Plum, Beech, and Oak are misleading names, not being like the English trees.

The Eucalypts, including the varieties of Gum, are valuable for more than timber. As anti-miasmatics the Gum products are most important. The great secret of the healthiness of Australia, even of the tropical portions of Queensland, is the exhalation from the forest. The aroma is not more pleasant than it is fever-chasing. The great febrifugal property of the Gum Tree family is supposed to lie in the eucalyptin, which is yellow in colour, without smell, but having a bitter taste. The leaves yield that substance in addition to fruit sugar and several distinct acids useful in the arts. The medicinal kino is obtained from the resin, though the kino differs according to the species. Gum leaves have been used there for the extraction of illuminating gas. From dried Red Gum bark $2\frac{1}{2}$ per cent. of kino tannin has been obtained, and $16\frac{1}{2}$ of kino red. The double oxide of hydrogen, got from Grey Gum, is a valuable antiseptic for hygienic use.

The Queensland Cedar is red, white, or pencil, prevailing in scrubs near the sea. The Moreton Bay Pine rises 200 feet. The Moreton Bay Fig throws down roots from the branches after the Banyan character. Some Figs are 40 feet round, having great wall-like abutments of the root aboveground. The Beech has a very hard wood. The Leichhardt tree is soft, but takes a good polish. The Kauri Pine is fine-grained. The Cypress is fragrant and useful. The Yellow-wood takes a capital polish, as does the Satinwood. The Chestnut has a dark walnut-like wood and magnificent foliage. The Silky Oak (a Grevillea) is admired by cabinet-workers and coopers. The mahogany of Rockhampton is hard and tough, red in colour, with a soft bark used for illuminating purposes. The Myall is a violet-scented Acacia, the wood of which is extensively used for tobacco pipes.—J. B.

DRAINAGE AND CULTIVATION OF THE SOIL.

No. 3.

ASSUMING the drains which have been previously referred to are all quite clear, we have made the first step on the road to success. The next important point is the cultivation of the soil. As the crops are cleared off the ground it should be trenched. Great care is necessary in the execution of this work. The nature of the soil and the depth to which it has previously been worked must be studied. If this is neglected a grievous error is soon committed, and instead of improving the soil it would, if trenched injudiciously, be in a far worse condition than before.

The proper way to set about the work is to line off a portion from 2 to 3 feet wide of the narrow end of the piece to be trenched, and wheel the soil from this to the end at which the work is to terminate. The depth of the first trench must be regulated according to the nature of the subsoil ; if clayey, only a small quantity must be brought near the surface at present, but the bottom must be well dug up and some good strong manure and lime, if at command, well incorporated with it. Then mark off the next trench and place the top soil of this on the bottom of the first, adding more lime and manure as the work proceeds ; but the dung in this case should be in a more decomposed state than that placed in the bottom of the trench, for the reason that it will be used by the next crop planted on it. This being done early in autumn or winter the surface soil should be left as rough as possible, so that frosts may act freely upon it, which will create a great change in any clayey portions that come within its reach. The winter's frost having acted thus beneficially on the soil, and with the addition of charred rubbish, this portion will be capable of producing first-class vegetables next season. After two seasons the soil broken up at the bottom of the trench will be in a fit condition to be brought to the surface and be treated as above directed ; but the bottom should again be dug up, lime and manure being added as before. By persevering in this matter for a few years an unfertile soil may be changed into a most productive garden. In the case of light soils, instead of mixing lime with them the addition of a little clay broken up rather finely would be most beneficial. In the case of very shallow soils, and where it is impossible to dig to any great depth, the only means that can be adopted is to cart or wheel any spare soil and manure on to the land and double-dig the ground. I have seen sifted coal ashes used as a means of rendering heavy soils of a more friable nature. This certainly makes the soil work more freely, but as I find no nutritive properties in it I would not recommend its use. Again, old tan has been employed for the above purpose, but it would do far more good on a meadow.

Having thus secured good drainage, and carried out the first year's trenching in a proper manner, we are prepared either for a wet or a dry season. For instance, in a wet season the drains are ready to take away superfluous moisture, and at the same time a current of air is passing through them, thereby keeping the soil sweet. In a very dry season the whole garden could not well be supplied artificially with water. Here, then, we have the advantage of the trenching, for if the roots of the plants cannot find sufficient for their requirements near the surface they will penetrate the earth until they find what they need.

I intend in another issue to pass a few remarks on the preparation of manure, and of creating the rubbish heap into one of the most valuable of manures for the gardener.—ROBT. D. LONG.

IRISES.—No. 11.

TURNING now to the last of the Apogon groups we have three or four handsome and interesting species that can scarcely be rivalled. The first and most important of these is the one represented in the accompanying engraving—viz., *I. Kämpferi* or *I. lævigata*, the latter being the name accepted by Mr. Baker and other botanists on the grounds of priority, but by the former it is best known in gardens. This exceptionally handsome Iris is a native of Siberia and Japan, and in the last-named country it has been cultivated for many years. It is remarkable that while the Europeans have been occupied in increasing the forms of the "English" and "Spanish" Irises, the Japanese appear to have given equal attention to *I. Kämpferi*, and they now possess a large number of magnificent varieties of which many have been introduced to this country during recent years. The graphic description of the Iris gardens at Hori Kiri, Japan, which appeared in the Journal for March 20th, 1879, was especially interesting, and I cannot forbear quoting the following passage which has special reference to the Irises:—"At last we arrive at the gardens, and then we obtained a full view of Iris in all her virgin glory, her head bright with rainbow hues as in classic legend of old. I had expected to see a grand sight, but I was completely astounded with that which now met my eyes. Thousands and thousands of plants are arranged in sunken beds flooded during the summer months with pure fresh water, and cut out with due regard to effect with grassy raised paths between, and hedged in by grass-clad knolls. Of course gorgeous bedding-out is no novelty to an Englishman who has seen the London parks, but this sight in early June was so thoroughly unique, so absolutely astounding, that I could only look on in wonder and amazement. Semi-double Irids there are here in abundance, some looking more like immense double Petunias impaled on long stalks than anything else, and many others having six immense outer petals, forming an almost perfect circle with an inner row beautifully reticulated and shaded with a great variety of colour from light rose and lavender to the deepest crimson and cobalt." From the beautiful varieties of this handsome species now in cultivation we can readily imagine what a grand effect would be produced by massing the plants as described above.

The typical form represented in the engraving has been dignified as "the finest of the genus" by several good authorities, and it undoubtedly has just claim to that honour. The figure fairly indicates the character of the flower, but the falls are occasionally more horizontally placed. They are of a deep rich purple hue, marked and relieved by a streak of gold at the upper portion, while the standards have a tinge of blue. Such is the type which, handsome though it be, has been far surpassed by the grand varieties introduced within the last seven or eight years. Messrs. E. G. Henderson & Son, Pine Apple Nurseries, Maida Vale, exhibited the first variety shown in this country—viz., the one named Edward George Henderson, which was submitted to the Floral Committee of the Royal Horticultural Society in July, 1874. It had large regular flowers, the standards and falls being nearly of equal size and spreading horizontally, of a deep purple tint marked with gold. It attracted considerable attention, and a first-class certificate was awarded for it by the Committee. Since then numerous varieties have been sent out by Messrs. Ware, Barr & Sugden, Bull, and Veitch, and those recently exhibited by the last-named firm at Kensington would very favourably compare with others previously in commerce. There is now a great diversity of colours from the purest white to the richest blue and purple tints imaginable, and this combined with the regularity of form and great size of the blooms render the progeny of *Iris Kämpferi* unsurpassed in its family. They have been frequently and not inaptly compared to Clematis flowers, to which in the great size and glowing tints of the perianth division they certainly bear some resemblance. It is difficult to select a few from so many of sterling merit, but the following are

some of the best :—Alexander von Humboldt, very large white, yellow-streaked flowers ; Fairy, lilac-purple ; Louis Van Houtte, flowers of great size, bright orange colour ; Lemoinei, pinkish tint, veined with rosy purple ; Frank Miles, fine rich purple, with a yellow blotch ; Dr. Hogg, deep velvety crimson ; Duchess of Edinburgh, fine claret purple-shaded flowers ; and lastly the varieties Crimson King and Magnificence, for which Messrs.

Veitch obtained first-class certificates at Kensington in July of the present year. There are many equally beautiful, but those enumerated indicate the range of colour in the flowers, and include some of the so-called double and single forms—namely, those in which the standards resemble the falls in size and shape, and those with falls as in the typical species.

With regard to the culture of this section of Irises, some growers

Fig. 47.—*IRIS KÄMPFERI* (*I. LEVIGATA*.)

appear to have encountered many difficulties, frequently losing their plants in the winter. However that may be in the northern parts of the kingdom, I think there is little danger of it occurring in the south if ordinary care be exercised. A well-drained moderately sheltered border is necessary, and a soil of peat with a small proportion of loam I have found to suit them admirably, not allowing them to suffer from insufficient water when growing

and flowering, or from stagnant moisture in the dull season of the year. With such little attentions to their peculiarities they are quite as easy of cultivation as many other species.—L. C.

THE WESTERN DISTRICT COTTAGE GARDENING SOCIETY.—The annual Exhibition of this old-established (since 1837) Society was held in a spacious marquee in the grounds of T. S. Bolitho,

Esq., at Penalvern, near Penzance, on Friday last, August 27th. It was the finest the Society ever held, and was perhaps without exception the best that has been held in Cornwall this year. Coleuses were well exhibited by Major Carew, who obtained first prize. Begonias were also well represented. For fine-foliage plants the chief exhibitors were Major Carew and R. F. Bolitho, Esq. (Mr. R. Wakely). Calceolarias were shown by E. Bolitho, Esq. (Mr. G. Maddern) and T. S. Bolitho, Esq. (Mr. Westcott); Balsams by Major Carew; Dahlias by T. S. Bolitho, Esq.; and Fuchsias by Major Carew and A. H. Michell, Esq. (Mr. Branin). The Caladiums were magnificent. Those exhibitors enumerated above were the chief prizetakers in the other plant classes, which were fairly represented. The chief exhibit of Pelargoniums was from Mr. C. Thomas, who has one of the best collections of Pelargoniums in the county. From E. Bolitho, Esq., Trewidden, came the largest and handsomest *Adiantum Capillus-Veneris* var. *cornubiense* in Cornwall: it was nearly 3 feet in diameter. Mr. Henry Hodge, St. Austell, contributed a good display of Gladioli spikes and cut Roses. Mr. Hender, Plymouth, exhibited some of his magnificent double and seedling Petunias and nearly a dozen varieties of Abutilons, also a truss of the new *Fuchsia Edelweiss*, which appears to be very good. Mr. George Fox had a stand of Dianthus and Pelargoniums. Mr. J. G. Mitchinson's stand was decorated with Gladioli, Roses, Marigolds, Asters, Dahlias. The products of the cottagers were without exception remarkably good, especially the vegetables.—W. ROBERTS, *Penzance*.

WASPS.

CAN anyone account for the extraordinary number of wasps this year? The two last years were so wet and unfavourable for them that it might have been expected that none would have been left. About this neighbourhood nearly all the bees have died, yet the wasps are more abundant than ever. I have tried many kinds of baits and traps: that described in last week's Journal is an old one, but the most successful I have found is the following—Take one ounce of quassia chips, one pint of beer, and one quart of water; boil these together, and sweeten with treacle or sugar. Place this mixture in broken jugs, mugs, or tumblers. Place the jugs near the haunts of the wasps, and go round every morning with a colander to drain off the insects, which will be found in the vessels in great numbers. Though my garden is a very small one, I have for the last two or three weeks taken out of my traps daily above half a pint of wasps, and they still abound.—G. O. S.

THE POTATO DISEASE.

IN my opinion the writer on this subject at page 194 is further astray in his assertions than he was before, and that was far enough, viewed from a practical standpoint. It is no great argument in favour of one who professes to be able to prevent or greatly mitigate the Potato disease that he has to substantiate his opinions by quotations from the *Times*. Practical cultivators of crops make the daily papers their last means of gaining reliable information on such matters; and the article quoted is no exception to the general rule, as it is impossible to conceive an assertion with less foundation than the following—"The ordinary gardener has gone on from year to year planting the same sort in the same plot of ground," &c. Now I am sure that ninety-nine gardeners out of every hundred will bear me out that the very opposite of this is the case annually. Gardeners now-a-days try more varieties of Potatoes than ever, and take greater care in growing them; and the extensive and excellent way in which the very newest varieties are grown and shown all over the country are matter-of-fact contradictions of the observations of the *Times* and your correspondent.

As for the same-plot-of-ground theory, there are numerous farmers on this estate who have grown Potatoes for the last thirty years and never have the crop on the same ground twice, and the disease in such seasons as the past and present is just as bad with them as others. Your correspondent is also wrong in assuming that I advise a "folded hand" policy, as the very reverse is the case; and I would say all praise is due to those who prevent or lessen such a terrible disease as that to which the Potato is liable; but a cultivator must prove himself thoroughly worthy of meriting that praise before it is accorded.

I shall not hesitate to express my disapproval of the writings of those who are unable to thoroughly verify their words by practice under long and varied circumstances. Let anyone consider the state of the Potato crop in any county in England, Ireland, or Scotland during the past and present season and say if my remarks are unreasonable.—A KITCHEN GARDENER.

THE author of the assertion that "about one-half of the losses

by the disease arises from the want of knowledge and apathy on the part of the growers," endeavours on page 194 to support his statement by a curious extract from a newspaper. There is a noticeable similarity of ideas expressed in the newspaper report and the paragraph preceding it. Our author says "we have been following a waiting policy for thirty-five years;" the report says "there is no matter of equal importance on which there has been less inquiry, less experiment, and less application of intellect."

Who, I ask, has been following a waiting policy? If the "we" simply means the writer of it I have nothing more to say; but if it applies to gardeners and cultivators generally, then I reply that there have been more Potatoes raised from seed during the last half of the period named, more varieties imported from abroad, more experiments made in preparing ground, trying manures, selecting and doctoring seed in endeavours to resist the disease, than during any other fifty years that your correspondent can name in the history of the Potato. Is this a "waiting policy?" Then as to the non-application of intellect. What is the meaning of the researches of professors at home and abroad—men of admitted eminence and great industry? What is the meaning of the extraordinarily voluminous writings on the subject that have been published in almost every newspaper in the land within the past twenty years? What is the meaning, too, of the bewildering number of experiments that have been made by men of science, professional gardeners, educated farmers, and intelligent cottagers during the period named in this and other countries? Does all this represent apathy and intellectual inactivity? To the minds of most people it represents precisely the reverse; and I may add that to this very intellectual activity and the working—not "waiting"—policy of others the author is indebted for the greater part of the interesting book he has published, about nine tenths of which is devoted to a discussion and narration of what others have written and done, his own practice being recorded on the remaining one-tenth portion of the volume. I fail, therefore, to see the foundation for the above statements—the apathetic and ignorant theory that is now advanced.

I suspect the Potato disease during the past thirty-five years has been of far more importance to me, personally, than it has been to your correspondent, and I should not be surprised if my experiments have not been more numerous and conducted on a more extensive scale than has his. I have further read all, or nearly all, that has been written on the subject in at least two horticultural and two agricultural periodicals, and have tried everything within my power that has been recommended for combating the malady. Ten years ago I felt well qualified to write a book on the subject, but subsequent experience has taken the conceit out of me. I have learnt how to proceed best in my own case; but all my notions, plans, and recommendations that I once thought so valuable for producing late and sound crops have in other seasons and districts been of no avail, and I am not ashamed to say that the only certain conclusion that I have arrived at is this: That when the summers are hot and dry we have no disease, and when they are excessively wet the crops that are out are practically ruined.

I have raised seedling Potatoes, and always selected the very best tubers for seed, the same practice having been adopted with reputed "disease-proof" varieties to prevent degeneration, yet my notions have been exploded and stock lost by the devastating murrain. I do not believe in "disease-proof" varieties, having seen too many fail, and I do not agree in the wisdom of writers in the general press advising the people to raise new stocks from seed. If small growers attempt that practice they will lose more money than they lose now. That is work for agricultural societies with large farms at their disposal and Government grants to carry out the experiments. Such grants are made for growing flowers in the London parks for the people to look at, and I for one think they might with equal reason be made in the endeavour to produce what private individuals have hitherto failed to do—an improved race of Potatoes that will resist the disease. The object to aim at is to raise varieties that will crop heavily and be as early as the Ash-leaves, and at the same time continue of good quality throughout the winter and spring. A dwarf Champion and Magnum Bonum would no doubt be very welcome, but we are travelling in a wrong direction by raising Potatoes that are exhausting the ground for three months after the early crops are dug. This suggestion may betray ignorance, but scarcely in alliance with apathy.

After long experience and close attention to the subject, embracing ten times more experiments than are referred to in "The Potato Disease and How to Prevent It," I have arrived at a totally different conclusion from the author on one important practical point. He advises that the tubers be planted 5 inches deep in early spring. I find that placing them on the surface and banking the soil over them is much better practice, as if the

summer proves dry the plants have a greater depth of good soil to root in and obtain support, while if it proves wet the excessive moisture can drain away to the certain advantage of the crop. I perceive that Mr. Ingram of Belvoir, who gave useful evidence before the Potato Disease Committee at the House of Commons, is also of this opinion. Planting 5 inches deep in March is only safe in light soils; on heavy land it as often fails as succeeds to produce the desired object—a full and sound crop. I do not wish it to be understood that I speak disapprovingly generally of the little volume I have mentioned; on the contrary, it is cheap at the price advertised in the Journal, and those who wish to possess a concise history of the Potato disease cannot do better than do as I have done, purchase the book.—A LINCOLNSHIRE POTATO GROWER.

CHAPTERS ON INSECTS FOR GARDENERS.—No. 10. NEW SERIES.

THOSE insects that have been already mentioned belonging to the Neuropterous order (sometimes called the Dragon-fly order, though it contains species which vary considerably from the insects popularly taken as its representatives), in their larval and pupal stages exist beneath the surface of the water, and are active from the moment they quit the eggshell. In the second division of the Neuroptera, to which is given the formidable-looking Latin name of *Subneocromorphotica*, the pupa is quiescent, and all save one genus have larva that are terrestrial and not aquatic. But before examining these we must briefly notice the curious little insects in the genus *Psocus*, which appear to stand midway between the two divisions of the Neuroptera. The head in the perfect insect is large, furnished with long antennæ and prominent eyes; the body has a squat look about it, and the wings are sometimes absent as in *P. pulsatoria*, the species that has received the unpleasant appellation of the Book Louse. It by no means, however, confines itself to books, but frequents bundles of old papers, and also dried collections of plants. The name *pulsatoria* was given because the insect was thought to produce a ticking sound at regular intervals like the death watch, but this is now believed to be a mistake. Dr. Hagen, in the "Entomologists' Annual," some years since endeavoured to vindicate the character of the species, asserting that it did very trifling harm to the books or other articles amongst which it is found. In spite of the Doctor's ingenious explanations we must think the circumstances are rather suspicious; the damage, whatever it may be, is done by the larva, a pale worm-like creature that glides rapidly off when an attempt is made to secure it. To preserve herbaria from the possible attacks of this *Psocus* all interstices should be closed against the entrance of the fly, and doubtless the odour of turpentine or any powerful aromatic oil would be a deterrent. Other species in this genus are found about hollows in tree trunks, old palings, and walls, where they probably feed either upon decaying wood or small lichens.

Proceeding to the lacewing flies we find a group of small insects, not without a resemblance to the dragon flies, but their wings, large though they are, seem to be of little service to the insects, their flight being sluggish. Hence they must form an easy prey to birds. Some are perhaps carried to their nests by the insect-eating species; but the strong and offensive odour that many of these flies emit when they are touched may serve as a protection against such attacks. The eye is an organ of remarkable brilliancy in the family, and in the dusk of the evening its golden or ruby hue renders one of these insects very noticeable. The common lacewing fly, *Hemirobius pirla*, is one of the important foes of aphides, though it can scarcely rival that of the *Syrphus* in its slaughter of these garden pests, if about equal in merit to the larva of the ladybirds (*Coccinellæ*). Reaumur, we find, called them Plant-lice lions, and he fancied they also preyed upon small caterpillars, a fact that we have not observed as yet. The eggs of this and other species of *Hemirobius* are placed upon footstalks resembling hairs, and arranged in clusters of from six to ten. Mr. A. J. Butler has watched the females in the critical operation of depositing these eggs. They first place upon the leaf a drop of glutinous matter, which is drawn up by the abdomen into a thread. After waiting a short time for this to dry the females lay an egg upon the point, securing it there by a drop of gum. The larva of this species is admirably fitted for its mode of life, having powerful mandibles and a muscular neck. It is the habit of *H. pirla*, and of its relatives that are also feeders upon aphides, merely to suck the juices of their victims, leaving a track of shrivelled carcasses as tokens of work accomplished. Should two of them meet they usually engage in a combat, the victor eating the vanquished at the conclusion. Many of these larvæ attain their full size in about a fortnight, spinning their compact silken cocoons on leaves or twigs. We have nearly fifty British species of the *Hemirobiidæ*.

The *Panorpidæ* form a small family, but although the species are few the insects are particularly conspicuous, being frequently seen in gardens, and also by the roadsides upon hedges or banks. These may claim to be ranked amongst useful insects from their doings both as larvæ and as flies. The popular name of "Scorpion Flies" applied to them has arisen from the conformation of the abdomen, the joints of which resemble those of a scorpion. The legs are of singular appearance when they are examined with a moderately strong magnifier, being ranged with rows of toothed spines and adorned also with spurs, while the comb-like claws at the tips remind us of a conformation noticeable amongst some of the spiders. In *Panorpus communis*, a familiar example, there is a forceps or pincers at the tail of the male insect; the female has a pliable ovipositor or egg-placer, by means of which the eggs are laid beneath the earth. The head, which has been said to be horse-like in its shape, is armed with a beak, by which the scorpion fly is able to pierce the bodies of the insects upon which it preys. In some seasons these flies help to reduce the numbers of caterpillars, which are naturally unable to escape from winged and agile insect enemies. The old naturalist Aristotle has described some flies with spotted wings that he observed upon the bushes in summer, and which seem to be the *Panorpidæ*; but he had not made acquaintance with the larvæ or grubs. These,

Fig. 48.—*Raphidia ophiopsis*: larva, pupa, and imago.

it has lately been discovered, live underground, feeding upon animal or vegetable substances that are undergoing decay. It is possible, however, that they occasionally attack the healthy rootlets of plants, though not to such an extent as to be productive of marked injury to vegetation; otherwise, the proceedings of the larvæ of scorpion flies must be called beneficial, putting them amongst the scavengers of insect parentage.

A curious insect allied to the *Panorpidæ*, but which stands alone, so to speak, is *Boreus hyemalis*. It is not much beyond the size of a large aphid with long legs, and wings only partially developed in the male, resembling a tiny hump on the back, therefore useless for flight. The female has no wings. From its habit of emerging during the depth of winter it is seldom noticed even by entomologists.

We quit the Neuropterous order with a brief mention of the last group that has to be considered, the snake flies. We possess five species in Britain that belong to the genus *Raphidia*, so called from a Greek word meaning a "needle," and which was suggested by the peculiar narrowing of the top of the thorax into a long neck which supports a broad flattened head. The wings of moderate size are strongly veined, but from the movements of one of these flies it may be thought that it is rather by dexterity than by speed that those insects are captured upon which it feeds. The snake flies are partial to the vicinity of ponds and ditches, though the larvæ are not aquatic; the few that have been detected were found under the bark of trees leading a predatory life. Our largest species is *R. ophiopsis*, its appellation implying that it is not only snake-like as to its neck but "snake-eyed" also. The larvæ is slim, and shows a snake-like resemblance as well as the fly it produces; for Prof. Westwood having captured one, observed that it crept along slowly, though when it moved "it gave the body violent jerks from side to side somewhat like those of a serpent." In size the snake flies approach the lacewing flies. The females have a long double-bladed ovipositor.—C.

HANDSWORTH FLOWER SHOW.

ON Wednesday last, the 25th ult., the inhabitants of Handsworth, near Sheffield, were very busy, it being the day set apart for holding the annual Exhibition of plants, flowers, fruits, and vegetables. It was the seventeenth meeting, and I hear the Show fully maintained its reputation, being quite equal on the whole to preceding years. Some classes were deficient in the number of competitors, such as those for Grapes, Peaches, and Nectarines, and other fruits, principally in the open class, while others were well filled, and the various prizes offered keenly contested. Owing to the season, which has not been a good one for fruit-growing here, the

outdoor crops are poor in most cases, and the quality not in many instances first-rate, while fruit-growing under glass has also been influenced by the season. The Show proper was held in a field adjoining the village, and was made up in three large tents occupying three sides of a square, which to those who, like myself, had not before seen Handsworth Show, would think by far too much space had been provided; but such was not the case, for with one exception (the tent for the open class), they were well filled. The classes were divided into four different heads—viz., for cottagers cultivating not more than 1 rood of land; amateurs cultivating not more than 2 roods, such not to be growers for sale; third, professional gardeners and growers for sale; the fourth open to all England. The ample space allowed all these classes to be kept distinct, which was a great advantage to the visitors. Besides the above great interest was centred in the various groups or collections kindly sent for show and not for competition; these were contributed mostly by growers in the neighbourhood, and added a grand feature to the Show. The principal of these were Mr. B. Crossland of the Richmond Nurseries, Handsworth, who exhibited a fine collection of stove and greenhouse plants, not the huge specimens such as are sometimes seen, but fair size plants of *Alocasias*, *Dipladenias*, *Caladiums*, *Cyanophyllums*, *Orchids*, *Aralias*, *Clerodendrons*, &c., as well as stove Ferns and dinner-table plants, all vigorous, healthy, and well grown. Mr. House of Peterborough also exhibited, while Messrs. Le Tall & Davis, seedsmen and floral decorators, Exchange Street, Sheffield, arranged a group of decorative plants as well as Grapes in three varieties, bouquets of the choicest flowers, &c.; their plants included Palms, Ferns, Fuchsias, *Dracenas*, *Liliums*, *Coleuses*, *Lycopods*, and other useful plants for decorative purposes; the free blooming of the flowering plants and the bright colours of the foliage plants attracted considerable attention. The famous nurseries of Fisher, Son, & Sibray have always contributed largely to this Show, but from some cause were not represented this time; the nurseries, however, were thrown open for inspection.

In the open classes Mr. T. Shelly, gardener to Mrs. Hobson, Burnt Stones, took the first prize for stove and greenhouse plants, six exotic Ferns, six British Ferns, and for six *Pelargoniums*. Mr. Boston of Bedale was first with twenty-four Dahlias, third with twelve, first with twelve fancy Dahlias, and first with twenty-four Hollyhocks. Mr. W. Slack of Chesterfield came in first with twenty-four Asters and twelve *Gladioli*, and third for twenty-four Dahlias. Mr. Haslam, Chesterfield, was second in both twelves of Show and Fancy Dahlias, second with twenty-four Asters, first hand bouquet, and second for black Grapes. Mr. T. Holland, Whittington, was second for twenty-four Hollyhocks. Mr. J. House, Peterborough, was a good first with a stand of twenty-four Roses, and Mr. C. Storey, Attercliffe, second. Mr. Bowling, Sheffield, third for a collection of fruit, first for two Pines, second with white Grapes, second for Nectarines, and first for a Vine in pot. Mr. Lyon, gardener to Lady Ossington, Ossington Hall, Newark, second for stove and greenhouse plants, second exotic Ferns, first for Peaches, and first for a collection of dinner table plants. These were much admired. Mr. A. Webb, Kilham Hall, Newark, second for *Gladioli*, first for a collection of fruit, and second for table plants; while Mr. Brabbs of Doncaster took first for black Grapes. Mr. Clayton, Grimston Park, Tadcaster, was second with a collection of fruit, first for white Grapes, second for six Peaches, and first for Nectarines. Mr. H. Cook of Woodhouse was placed first for twelve Dahlias, second for twenty-four Dahlias, and third with Fancy varieties. The above list of prizetakers will be sufficient to show that the open classes were good. The prizes in the remaining three divisions were equally well contested, especially in the amateurs' classes, where the vegetables were a strong feature, but the cut flowers with one or two exceptions were not quite up to the required or usual standard.

In the cottagers' division the numerous competitors made an excellent display in every class. I ought not to omit to mention that there were twenty-six donors of special prizes in addition to those offered by the schedule. Another matter to be thought of was the designs for flower gardens of villa residences. There were several of them exhibited, and there is a great amount of credit due to those who design them. In addition the Society offers substantial prizes for the best-managed cottage garden in the village. There are two classes, professional and non-professional gardeners, defined as those who work in a garden and those who are otherwise employed. Both classes were most creditable. So far, then, the Handsworth Show was one of the best I have seen as a local show, and is looked forward to with a great amount of interest by the Sheffielders, for being of easy distance (about four miles) hundreds of people from that busy town go to see it. Financially I hear the Show was a success, as nearly £200 were taken at the gates.—THOMAS RECORD, Sheffield.

THE POTATO CROP IN IRELAND.—I have just arrived in Dublin after a run through Munster and the greater part of Leinster, and after having an opportunity of closely examining the crops in many of the best-conducted gardens, including the Government Model Farm and Garden at Glesnevin, and the unanimous opinion of all cultivators is that the crops are much above the average of the past ten years. The Potato crop is large in quantity and superior in quality. I saw by notes in the Journal before I left Clonmel that Champions were affected by blight in England. I have examined them in several counties, south and

midland, and you will be glad to hear I found none of them diseased in Ireland.—W. J. M.

DRACÆNAS.

OWING to the great multitude of plants serviceable for decorative purposes, both for foliage and floral display, it is sometimes puzzling to know what to cultivate. Limited space has frequently to be taken into consideration, and a question is frequently raised in the mind of the cultivator as to what is best from all stand-points for him to grow or discard. Now, without the slightest hesitation, we are willing to give *Dracenas* a high place amongst the most valuable of decorative plants. Their graceful growth, colour, and form of leaf, well justify such an arrangement. These characters render them beautiful and extremely useful for all kinds of work, whether it be the embellishment of plant houses, special effect in subtropical bedding, and last but not by any means least, the ornamentation of rooms, as table plants, and for numerous and various other purposes. They are fairly enduring in gaslight, lasting some time in good condition.

Having, then, in *Dracenas* a useful class of plants, it is well to secure them in quantity; and be it understood we have not much to remark upon their propagation, which is well known. A few methods are, however, easily described. When a specimen becomes too high it may be shortened to any extent, and rooted at any portion of its length in the following way: Divide a small pot evenly, so each half will meet, enclosing the stem and secure them, having previously cut the stem about half way through with a sharp knife; fill the pot with suitable soil, and roots will soon be produced. The tops may also be rooted freely in a steady bottom heat of 80° or 85° Fahr. Having removed the rooted top there is abundant material below for a batch of young plants. Some growers take the stems, removing the soil from the roots, and lay them in the propagating case and allow them to grow, which they do quickly and freely, when the young shoots are removed and easily rooted, plunged in bottom heat singly or several in pots. This is a very good method and one extensively performed. It is also a good plan to cut the stem and primary roots into short lengths, say an inch long or less, and place them thickly in pots or pans, plunging the latter in brisk bottom heat, when they readily start and soon form fine young plants ready to leave the case. A propagating case is not a necessity for increasing the stock of these plants, as young shoots potted will root freely enough in an ordinary stove temperature, but like most plants they can be increased more quickly and better with case treatment. There is no particular time to be given when they should be propagated—that must be ruled by the requirements. The two essentials for growing them well are heat and moisture; shade is also necessary during sunshine—they do not like bright sunshine. During the spring and summer a temperature of from 75° to 85° with the house well charged with atmospheric moisture is suitable. Copious supplies of water at the roots is also indispensable during such rapid growth. If a house has a hot-water tank in it so much the better, and frequent use of the syringe is conducive to their good in more ways than one. It lessens insect pests if any are present, and keeps the foliage clean.

As to the soil most suited to them, the following I have found the best. Peat is employed sparingly. Good mature fibrous loam well charged with sharp sand is the staple soil; peat is employed to a limited extent; well-decayed manure is also used. I have found Mr. Wills' horn manure most beneficial, having employed it freely. Some growers use a large amount of peat, but I cannot recommend it. Good drainage is essential, and the pots should not be too large. For general purposes 48-pots are sufficient. The following is a selection of the best *Dracenas* in commerce:—

D. amabilis.—A well-tried variety of great merit, producing long lanceolate leaves, which are light green, copiously marbled and streaked with white and rosy-pink, rendering it very effective, as the leaves curve gracefully. Easily grown and largely employed.

D. Baptistii.—A fine-foliaged form, the leaves measuring 2 or 3 feet in length, finely margined and streaked with white and rosy pink, and very spreading. It is a beautiful variety.

D. Barronii.—This is similar but superior to *D. Youngii*, therefore I omit any further mention of the latter. The leaves are oblong, 5 or 6 inches broad, of a dark bronzy green with an irregular edging of deep magenta colour, the young leaves being considerably lighter in colour. The habit is good.

D. Bausei.—A grand variety, very effective, of a dwarf compact habit, producing oblong volute leaves, about 3 or 4 inches broad and very closely overlapping each other, of a dark metallic hue, with crimson margins, the young leaves having very broad bands of a lighter tint; the petioles are also coloured. This variety

is not very plentiful, but it is a grand addition to our ornamental plants.

D. Elizabethæ.—This variety is very handsome. The leaves are sharply curved under each other, copiously produced, and the plants are very compact. The leaves measure about 4 or 5 inches across, dark green, with a narrow crimson edge on the older leaves; the younger with a broad band of rosy pink and white, or creamy white. Of very free growth, and colours early.

D. elegantissima.—An older variety, but very good, being of very close growth. Leaves narrow, gracefully curved, of a dark metallic hue, with the margins crimson; in the young foliage much lighter. Very effective as a decorative plant.

D. Cooperii.—A form largely employed, and extensively grown for the markets. It is a free grower, easily done, and of rich colouring, the foliage when mature being bronzy red margined with crimson; the younger leaves magenta crimson. It differs from *D. terminalis*, and is more tender.

D. Goldicana.—One of Mr. Bull's introductions, very distinct from all other *Dracænas* known in cultivation. It comes from tropical Western Africa. The leaves are closely set on the stems, having a sheathing petiole; the lamina is cordate ovate, with acuminate points, alternately banded with dark green and silver grey upon the upper surface; the under surface is purplish. It is very free-growing, but not so readily propagated.

D. Gladstonei.—This variety is of very hardy constitution, growing freely, and readily increased. It should become very serviceable for general purposes. The leaves are gracefully recurved, 3 or 4 inches broad, of a dark bronzy colour; the younger leaves of a deep crimson colour suffused with salmon rose, rendering it remarkably effective.

D. gracilis.—A narrow-leaved well-known variety, very useful for many purposes. The leaves are densely produced, very narrow, gracefully bent, light green with a dark midrib.

D. Hendersonii.—This is of good habit. Leaves 1 to 2 feet long, 3 to 5 inches broad, light green, marbled and striped with yellow and light pink.

D. ferrea.—This is not so much esteemed as many, but is very effective, especially in a young state; the foliage is very dark, rather rigid. For mixing with other plants it is very effective.

D. Imperator.—A handsome form. The leaves are oblong-ovate, dark green, with dark purple edge; the younger leaves have broad marginal variegations of pink and white, tinted more or less with magenta, the under surface of the leaves deep purple.

D. nigro-rubra.—A variety largely employed for market purposes, and is extremely useful; it is too well known to need description.

D. Nitzscheii.—This produces copious broad oblong leaves, sharply recurved, dark green; the younger are variegated with creamy white tinted with rose, while the mature leaves have a narrow margin of crimson, which is continued down to the edges of the petioles. A very distinct and desirable form as a contrast to many others.

D. Regalis.—Similar in habit to the last, very robust; leaves oblong, recurved, deep bronzy green, irregularly margined with bright red, which is also continued to the edges of the leafstalks; the young leaves are broadly edged with creamy white, suffused with pink. Very bold and free-growing.

D. terminalis alba.—A valuable variety; extensively grown for decorative purposes; the leaves are lanceolate, 2 or 3 inches wide, dark green, margined with creamy white, the young leaves almost pure white. It is a splendid variety for mixing with the dark varieties.

D. Salmoinea.—The leaves are sparsely produced, with long stalks and lanceolate narrow blades, the latter of a deep green colour distinctly margined with salmon pink, which is also extended down the edges of the petioles, which render it very different from others.

D. Sidneyi.—A narrow-leaved variety, much esteemed. The footstalks are long, and the laminae are narrow, lanceolate, dark green, with crimson edges; the younger leaves entirely of a rosy-crimson colour. I find it free-growing and useful, as it certainly is very graceful for table decoration.

D. Tellingi.—A very strong-growing variety, and exceedingly free. Leaves oblong, more or less recurved, of a dark bronzy green colour edged with rosy pink, which deepens as they mature. As an effective variety it is in the first rank on account of its broad foliage.

There are a host of others known to growers, but the above selection will give a good display.—T.

TRAINING YOUNG VINES.

WE have frequently noticed what we consider an error in training young Vines at the stage generally termed their first and second fruiting years. The system usually practised of training

young Vines the year they are planted, is to allow them to ramble and make as much wood and foliage as covers the whole roof without crowding. A Vine trained in this way makes extended lateral growths, and the result is the manufacture of a great amount of roots; and the Vine, if cut down, is expected to send up a fruit-bearing rod the second year of greater strength than if the previous season's training had been more restricted. But if the Vine is not cut down, and the extensive lateral growth pruned away, and the main stem shortened back and allowed to fruit the second year, the result in Grapes is never so satisfactory as when the first year the laterals are pinched at the second, or at most the third, leaf or joint. In the former case the buds are formed on the main stem, and produce fruit-bearing breaks the following year, but are never so plump and fine as in the latter, when the growth of the Vine is more concentrated.

The remarks we have just made apply with equal force to the training of permanent Vines in what are termed their first and second fruiting years. The first fruiting year, the common practice is to cut back the previous year's growth, so that the Vine bears over about a third of the length of rafter or roof of the vinery, the other two-thirds of the space being left for the production of growths to bear fruit the following or second year of fruiting. In these cases we have often seen their lateral growths allowed to extend and cover all the roof space, besides a portion of them being trained down the back wall. Under such training we never saw the fruit-bearing growths, nor the fruit on the bottom portion of the Vine, so strong as we like to see them. And when pruning time comes round, they are not so well furnished with buds for producing fruit-bearing breaks the following season.

A very striking illustration of this came under our notice a week ago. A house full of young Vines of great strength, generally had weak fruit-bearing lateral growths about half-way up the roof, and the bunches were nothing to what such Vines under different training ought to produce. The young rods at the upper part of the vinery were allowed to extend their lateral growths in all directions, right and left, and down the back wall. They were, in short, robbing the fruit-bearing lateral growths lower down, and, as a consequence, robbing the bunches too. Nor is this the only evil; for the buds that were to produce fruit-bearing breaks on the top young rods were flat and unsatisfactory, owing to the great lateral growth allowed.

What we consider the better system of training such Vines is just the reverse of that referred to—viz., to let the fruit-bearing growths on the lower part of the Vines make a lateral growth of a joint or two, and let them cover all the space available with growth, and to restrict the lateral growths in the main stem above to, say, two joints, or just as many as will prevent their bursting their main buds. This would secure finer shows of fruit the year following both on the top main stem and from the lateral and lower growths when spurred back at pruning time.

No doubt it has often been noticed, when a Vine is allowed to develop itself in any particular part for a year or two, how in former years it had a tendency to send its strongest growths from that locality. Also, in removing a limb from a vigorous healthy Vine, we have, time after time, had lateral buds forced with great vigour from the locality at which the amputation was made. This, we consider, teaches the desirability of distributing the force of the Vine, when establishing itself for permanent bearing, more equally than is the case when young Vines are allowed to make rambling top growth, while the lower fruit-bearing shoots are being robbed and starved.—(*The Gardener*.)

KITCHEN GARDEN.

Cauliflower.—Seed should be sown at once in an open situation and not too thickly, as the plants are very liable to damp off in the seedling state at this time of year. Attention will be necessary to save the seeds from birds, and the plants from the depredations of slugs, and should mildew appear dust the plants with quicklime. Plants from this sowing must be transferred to handlights or frames, and will afford heads succeeding the late Broccoli. The best varieties for this sowing are Veitch's Early Dwarf Forcing, Early London, and Walcheren.

Lettuce and Endive.—The seed for next season's early supply of Lettuce should be sown in an open situation. Stanstead Park is the best Cabbage, and Black-seeded Brown the best Cos variety for this sowing. As the plants from later summer sowings of Lettuce and Endive become ready plant out good breadths in firm soil to induce a sturdy growth, as Lettuces in autumn have a tendency to become soft, and those grown in firm soil are not so susceptible of injury from wet and frost as those in loose rich soil. Take advantage of sunny days to tie up such as are fit for blanching, and earth up the most forward crops of Celery in favourable weather. Continue to sow Radish and Mustard and Cress seed in warm situations.

Cabbage.—Plants from the July sowing may when ready be placed out where they are to remain, selecting rich soil in a sunny situation, a distance of 18 inches apart every way being ample for the plants. By planting out another batch in a fortnight's time in an open situation a good succession of early Cabbages will be ensured.

HARDY FRUIT GARDEN.

There is still time to plant Strawberries; and if the plants that are well rooted in small pots are turned out now, and well attended to with water if the weather prove dry, they will afford some fine fruit next season. Where it is necessary to defer planting until spring, runners may now be pricked-off in nursery beds. Runners planted some time ago will be making good progress, and should have the secondary runners removed. Older plants should now be cleared of all runners and weeds, so as to admit of light and air to mature the crowns. Continue to attend to stopping and thinning the growth of fruit trees, as, owing to the moisture and scanty crop, they are making much growth, especially bush and pyramid trees, which should now be examined, and the laterals stopped to one bud, so as to check late growth and strengthen the buds for next season. Peaches and Nectarines will require attention in stopping laterals and cutting back gross growths, as for the wood to ripen properly must be well exposed to the sun's influence.

FRUIT HOUSES.

Vines.—Former directions with regard to the starting of late houses having been followed the Grapes will be well advanced, and instead of keeping the Vines excited by sharp firing, as is the case with houses started late in the spring, atmospheric moisture may now be gradually reduced, and well-ripened wood with highly finished fruit will be secured by the application of sufficient artificial heat to keep up a circulation of warm dry air. The Vines will rest before the long damp nights set in, and the bunches will keep satisfactorily in a suitable room, and this will admit of the pruning of the Vines and giving them a long rest. Vines from which the Grapes have been cut must not be neglected, keeping all laterals closely stopped, securing a dry warm atmosphere to ensure the complete maturity of the wood. The old foliage should be retained as long as possible, keeping it free from dust and red spider by an occasional washing with the engine on fine evenings. Where early forcing is contemplated the Vines should be pruned by the middle of September, the houses cleaned, repaired, and painted if necessary; the borders being cleared of the old mulching and loose soil, supplying a dressing of good turfy loam to which a twentieth part of half-inch bones has been added.

Cucumbers.—As the nights are becoming cooler less syringing is needed; it must be done earlier in the afternoon, and the ventilators should be closed earlier, but there will not be any necessity for fire heat unless the night temperature falls below 65°. Much depends upon local circumstances, the size of the house, elevation, and aspect, so that the cultivator must be guided by them, it being impossible to lay down rules generally applicable. Encourage the plants for autumn fruiting, removing the first fruits, also the staminate blossoms and tendrils. A sowing should be made from now to the middle of the month to provide plants that will supply fruit at Christmas. Telegraph is the most reliable variety.

Melons.—The last batch of plants will be making good progress, and should not be stopped until the leaders have advanced two-thirds up the trellis, removing every alternate lateral directly they can be pinched out, maintaining a warm and moist atmosphere until the fruit is setting, when less moisture is needed. The latest plants in frames have set their fruit well; earthing up the roots must be attended

to directly the fruits commence swelling, watering copiously in dry weather, and keeping a strict watch for canker at the collar, and applying quicklime should it appear. Keep the laterals well stopped, shading only to prevent flagging. Gradually withhold water at the roots, and atmospheric moisture from plants ripening their fruit.

FLOWER GARDEN.

The early summer months were not favourable to a development of bloom on Pelargoniums and other flowering plants, and the growth of the tender varieties has been greatly retarded; but the better weather of late has wrought a change, and flower gardens will be in fine condition during the present month. Remove all decayed leaves, faded flowers, and seed pods from plants in beds, and in dry weather supply water copiously. Although there is a slight departure from summer bedding in favour of herbaceous plants, which have been unusually attractive this season, carpet bedding has increased in popular favour, and deservedly, for when well done it is very beautiful. The propagation of bedding plants must now be pushed forward. Cuttings of the common varieties of Pelargoniums may be inserted in boxes of sandy soil; if these be placed in a warm situation the cuttings will root freely. Choicer varieties may be inserted in pots and placed in a frame where they can have protection from heavy rain. A few store pots or pans full of Verbenas, Lobelias, and Heliotropes will be sufficient, as they are freely increased in spring. Cuttings of Pansies and Violas strike freely in a shady border; the cuttings should be taken from the base of the plants.

Herbaceous plants should be examined frequently, removing all dead stems or stalks; others will require staking and tying, such as the late-flowering Asters and Chrysanthemums. Seeds of hardy annuals should now be sown; when surviving the winter they make a fine display in April and May.

PLANT HOUSES.

Pelargoniums.—Cut down the latest-flowered plants, placing them in a pit or frame. Very little water is necessary. These first cut-down plants will be ready for shaking out, as it is not well to let the shoots become much advanced before repotting, or the reduction of the roots will cause many to cease growing. Half the roots may be cut away from old plants that are as large as required. Turfy loam with a sixth of old manure is a suitable compost, adding a sprinkling of sand. They should be potted firmly, and placed in a light house near to the glass, and damped lightly every afternoon, admitting plenty of air.

Mignonette.—Encourage the plants to make strong growth by keeping them near to the glass and shifting as required. A few plants grown well will afford more and finer spikes of bloom than as many dozens badly grown. Plants intended to form standards should be kept to single stems regularly tied up to stakes, and when of the required height they should have to be trained over an umbrella wire stand. Green aphides must be destroyed by syringing with tobacco water or moderate fumigation.

Roses.—Plants in pots that have been well attended during summer should now be placed in an open sunny position to ripen the growth; and if there is any trace of mildew promptly apply flowers of sulphur, as unless this is destroyed it will give much trouble when the trees are under glass. Where potting is necessary it should be done without delay, placing the trees at the back of a wall or fence for a few days. Clematises are valuable for decorative purposes, and should be placed in a sunny situation similar to the Roses, affording water so as not to stop growth all at once, at the same time taking care not to allow the soil to become too wet by heavy rains, or the growth will not ripen well.

Plants of *Anemone japonica alba* lifted before the buds are too much advanced, potted, and placed on a north border for a few days and kept moist, will make fine specimens for conservatory decoration. Dwarf Asters may be taken up from the borders and potted three or four together in a 6-inch pot, and if the soil is well soaked to prevent the plants flagging they will be found very useful for decorative purposes.

Richardias.—Plants that have been retained in pots will be starting into growth and should be potted at once. It is only necessary to

remove the soil not occupied with roots; turfy loam with a fifth of well-decayed manure suits them well, providing good drainage, as copious supplies of water are necessary. Supply weak liquid manure freely, as the spathes are fine in proportion to the vigour of the plants. Those planted out may be lifted and potted at the end of the month, and be placed under cover before frost.

Solanums that have been planted out should now be lifted and potted in 6 or 7-inch pots according to the size of the plants, and as soon as potted they should be placed near a wall or where they will be sheltered until they commence growth. Attend to Tree Carnations for winter flowering, placing them in a position where they will receive all the light possible, so as to keep them dwarf and stout, as upon this depends the production of flowers in quantity. Hydrangea cuttings from plants that have formed the buds if now inserted strike readily in gentle heat, and form much dwarfer specimens than those struck in spring. Take off the cuttings with about three joints and insert in small pots, in which they may be allowed to flower, as plants in 3 and 4-inch pots give fine heads if supplied with liquid manure.

Roman Hyacinths.—Place four or five bulbs in 6-inch pots, or in pans, as close almost as they can be placed to yield flowers for cutting, employing turfy loam with a fifth of well-decayed manure and a little sand, covering the pots with about 6 inches of ashes or cocoa refuse. The plants will soon fill the pots with roots, and should before top growth is much advanced be moved to a position near the glass in a light airy house, from whence they can be removed to warmer quarters to accelerate the flowering; but they must be kept near the glass. Indispensable as are these general favourites, the Paper-white and double Roman Narcissus are almost as requisite; hence they should be now potted, receiving the same treatment as the Hyacinths. They will come in at about the same time, flowering by November with gentle forcing, or in an ordinary greenhouse in December. The Guernsey and Belladonna Lilies also will need to be potted at once.

Violets.—Plants that have had the runners removed from them, and have been kept free from weeds since they were planted out as rooted runners or suckers in spring, will now have formed good crowns. Such as are intended for planting in frames or pits should be lifted with balls and placed in rich soil, giving a thorough soaking of water and keeping off the lights until frost. If deferred until later the check consequent upon removal retards the flowering.

TRADE CATALOGUES RECEIVED.

James Carter & Co., High Holborn.—*Illustrated Catalogue of Bulbs.*
Charles Turner, Royal Nurseries, Slough.—*Catalogue of Bulbs and List of Strawberries.*
George Bunyard & Co., The Old Nurseries, Maidstone.—*Catalogue of Roses.*
Samuel Yates, 16 and 18, Old Millgate, Manchester.—*Illustrated Catalogue of Bulbs.*

Book (S. M. W.).—We regret we are unable to answer your question. If you can state the subject in connection with which the work was mentioned we may possibly be able to find what you require.

The Hampton Court Vine (J. Jones).—There are between twelve and thirteen hundred bunches of Grapes at present on the above Vine, their aggregate weight being estimated at about 600 lbs.

Notice to Quit (A Cottage Gardener).—No one can possibly understand the case as you have endeavoured to state it, and the only safe course for you to adopt is to consult a solicitor.

Nicotine Soap (A Victim of Bug).—This insecticide has been advertised in the Journal by the manufacturers, Messrs. Corry & Soper, who state that it can be had retail from all seedsmen and florists.

Melons under Rough Glass (Bredbury).—Rough plate glass is unsuitable for pits and frames intended for Melons, as it is only during very bright summers that the fruit can be depended on to ripen well and assume a high flavour in such structures. Much the same remarks apply to Cucumbers—i.e., such good crops cannot be depended on under rough as under clear glass.

Peaches Decaying (R. E. H.).—The specimen was very much crushed on arrival, but so far as we are able to judge by an examination of the decaying mass the fruit appears to have been punctured by some insect, it may be by the

larvæ of a Tortrix. Search carefully, and you may possibly find a small inconspicuous caterpillar, and if so you may conclude it is the cause of the mischief.

Grapes Cracking (R. S. O.).—The Madresfield Court Grape is more liable to crack than many other varieties, and we have observed that it often cracks the worst when the crop is light in comparison with the vigour of the Vine. Possibly if you notch the wood just below the bunches, and so check the flow of sap to the fruit, that you may mitigate the evil. Mildew may be destroyed by dusting it with sulphur.

Land Valuation (J. B.).—It is impossible for anyone to answer your questions satisfactorily without an inspection of the land and possessing some knowledge of the district. The land in some localities is steadily increasing in value, and the increase in time may be considerable, while in other places the reverse may be the case. It is only by a full consideration of these circumstances that the leasehold value of the land can be obtained, and whether long or short leases are likely to be the most advantageous to the occupier. Consult someone in the neighbourhood who has good practical knowledge on the subject. In no other way can you act with safety.

Plants at the North Pole (F. N.).—In 1873 Capt. A. H. Markham collected, chiefly at Fury Beach, *Ranunculus gracilis*, *Papaver alpinum*, *Lychnis apetalum*, *Stellaria Edwardsii*, *Dryas octopetala*; *Saxifraga cespitosa*, *S. nivalis*, *S. flagellaris*, and *S. oppositifolia*; *Pedicularis hirsuta*, *Juncus biglumis*, *Salix arctica*, *Alopecurus alpinus*, *Festuca ovina* var., *Pleuropogon Sabini*, *Platysma juniperinum*, and *Alectoris ochroleuca*. There have also been found there *Draba alpina*, *Cerastium alpinum*, *Taraxacum Dens-leonis* var., and *Poa flexuosa*. These were collected in the highest latitude from which flowering plants have hitherto been obtained. Of these the *Pleuropogon* is the only genus absolutely confined to the Arctic regions.

Painting Greenhouses (J. E.).—We scarcely understand your question. You ask for the "best form of stage for painting the roofs." The term "stage" implies that you mean the inside portion of the roof, as only ladders are required on the outside. For this purpose a "box ladder" is employed in some places, the steps being flat, and boarded from the back edge of the lower to the front edge of the step above it, the steps being of a suitable angle for the roof. A workman cannot touch the glass with his feet when on a ladder of this kind. Such ladders, however, are heavy, cumbersome, and rather expensive, and most painters can do very well without them with an ordinary ladder placed on battens and a board placed under the ladder. If you refer to the inside of the roof the "stage" must depend on the arrangement of the house, and a painter will be able to suggest the best form for using.

Summer-pruning Fruit Trees (Idem).—All the breastwood and superfluous growths of Apple and Pear trees should be removed at once, shortening them to about four leaves next to the main branches. The buds so left will not produce a second growth now; perhaps the top one may do so, but it can be pinched, or left to be removed at the winter pruning. Of course any shoots required for further branches and the extension shoots for occupying further space must be retained.

Removing Potato Haulm (Idem).—After the disease is clearly present in the foliage and stems it is no use removing the haulm for the preservation of the tubers, but if the haulm is removed before the foliage is affected the tubers will be safe. We have not known it necessary to remove the haulm of Magnum Bonum, the stems of which appear to contain much woody tissue, which possibly arrests the spread of the mycelium of the fungus, and the tubers are left in comparative safety. The more fully the stems and foliage are exposed to the air the firmer they become, therefore thin planting should be adopted.

Tea Rose Luxuriant (S. H.).—It is not easy to advise you without knowing the condition of the other portions of the plant. If the other growths are healthy, fairly strong, and well placed for covering a wall, it would be prudent to shorten the luxuriant shoot so as to equalise the sap and form a good foundation for a healthy plant. If the other portions are very weak the shoot may grow unchecked for the purpose of encouraging root-action, and be shortened as required in the winter, the weaker growths being cut away.

The Trebbiano Grape (W. A. B.).—To have this Grape in good condition it requires a higher temperature than is necessary for Black Hamburg and Foster's Seedling. The Grapes sent, owing to having been loosely placed in a tin box, were so much crushed by being shaken in transit as almost to be unrecognisable, while the juice saturated the letter accompanying them, reducing it almost to pulp. The Vine should have the benefit of fire heat now for maturing its growth, nriple wood being the source of many failures in Grape culture.

Propagating and Wintering Tuberous Begonias (F. B., Norwich).—If you insert strong healthy cuttings at once in sandy soil in a propagating pit they will emit roots speedily, and form small tubers before the winter. The cuttings must only be shaded to prevent flagging, and must be inured to light and air as soon as possible to induce healthy growth. After the growth has died down we should plunge the pots in slightly moist cocoa-nut fibre refuse in a temperature of about 55°. If the small tubers are kept too dry they will shrivel, and if too wet they will decay, especially if in a low temperature. You must not expect every tuber to grow in the spring, for even when great care has been exercised in preserving them a number of tubers not infrequently refuse to start. We should insert the cuttings singly in 3-inch pots, and winter the tubers in the same pots, as it is too late for inserting cuttings to be potted off this autumn.

Propagating Bedding Pelargoniums (T. J.).—No one can tell what the weather may be a week after writing. In ordinary weather, and the soil being moist when used, the cuttings would receive no harm from not being watered during that period. In dry weather a good watering may be given; but had showers prevailed, as they have done heavily in some districts, artificial watering would have proved deleterious. The soil should not be dust dry for long together at any time. Seed of *Anbrietias* sown now will not produce plants that will flower next spring. The same remark applies to perennial *Alyssums*.

Second Crop of Figs (X. F. Z.).—If the trees are in a house to which heat can be applied the shoots may be pinched above the fruit, which will then ripen, a proper temperature being maintained. If the trees are in the open air and in a weak state, the incipient fruits had better be removed; but if the trees are luxuriant the second crop will do no harm if left on until the fruits shrivel and drop off. Without knowing to what trees you refer as being unhealthy we are unable to suggest the cause of their unsatisfactory state, but we know that many forest trees were considerably injured by the prolonged severity of last winter.

Shaw's "Market Gardening" (Inquirer).—Owing to an extraordinary press of matter that we have experienced for some months past we have been reluctantly compelled to defer the publication not only of notices of some books,

but also of communications of value and interest that have been kindly sent to us by various correspondents. Failing an opportunity of referring more fully to the book in question, we now say of it briefly that it is a small work on a great subject. It is written by a practical and observant gardener, who has very fairly described what he saw in his visits to several large fruit, vegetable, and flower-growing establishments, and recorded what he learned during such visits. As the leading growers of garden produce for market do their work well the cultural remarks embodied in the chapters are sound, and may be usefully adopted by many gardeners and cultivators of the soil.

Alsophila australis Unhealthy (*E. Sheffield*).—In all probability the wet and cold soil has caused the roots to decay, a process that would be greatly accelerated by the injury to the foliage by the sulphurous fumes to which you refer. If the roots are dead round the outside of the ball formed by the pot, from which we presume the plant was removed, it is no use packing fresh peat round them. You had better take the plant up and carefully remove the soil until you find live roots, removing all that are dead, then either pot the plant again or place a fresh sweet compost of turfy peat and broken charcoal round the roots, and if carefully watered that will promote the emission of fresh roots. At the same time syringe the stem of the plant frequently, keeping it moist, also the atmosphere of the house, and in due time your plant may recover. You cannot, however, expect it to thrive if fumes from the stovehole are permitted to enter the house.

Seedling Pelargonium (*A Gardener's Wife*).—We are sorry to inform you that the flowers of the Zonal Pelargonium shared the fate of nine-tenths of those that are sent to us when a little clear gum has not been dropped into the centre of the flowers to seal the petals. The moment we opened the box all the petals fell except from one flower. If the others are equal to this the variety is one of the best that has been submitted to us for a long time. The flower is perfectly circular, with stout smooth velvety petals, the colour being rich scarlet with a small clear white eye. The truss is good; and if the foliage is also good, the habit sturdy, and the plant floriferous, we consider the variety well worth preservation; but whether it is distinct from other varieties in commerce it is impossible to say without comparing it with those in a very large collection. We are glad that, like many other gardeners' wives, you take such an active interest in your husband's work. Such encouragement is helpful, sweetens labour, and not seldom contributes to success.

Dwarf Cabbage (*Rev. J. A. W.*).—No one could possibly identify the Cabbage from the specimen sent. If the plant that produced the heart, and which is of the size and shape of a swan's egg, received no check during any period of its growth, but was a full and well-grown specimen, we suspect the variety is distinct. By all means preserve the plant, protecting it with a hand-glass if necessary during the winter, and before the flowers expand in the spring envelope them with gauze to prevent insects having access to them. This is very important, as it is essential that the flowers be fertilised with their own pollen to ensure the perpetuation of the variety. If you succeed in raising a number of plants identical in size and form with the parent, we think you will be justified in attaching a name to this diminutive Cabbage; and if the variety proves very early as well as very small, it is likely to meet with considerable favour from cultivators.

Muscat Grapes Shrivelling (*A Fourteen-years Subscriber*).—It is not possible for Grapes to swell and ripen when so much infested with thrips as yours appear to be. Not only are what you term the "best" sample of leaves covered with the insects, but they have almost entirely destroyed the epidermis of the footstalks of the fruit, and so restricted the flow of sap which is essential for the swelling of the Grapes. The great injury which the foliage has sustained must also have checked the root-action considerably, and the Vines are not in a condition for carrying a heavy crop next year. You must first destroy the thrips by sponging every leaf, and when the Grapes are cut syringing with an insecticide, and fumigating. You had better also encourage the growth of laterals and keep them clean. You do not state the age of the Vines. Possibly they would be benefited if the roots were lifted and placed in fresh soil, for judging from the appearance of the leafstalks we think the Vines are deficient in vigour. You must clearly understand, however, that they cannot possibly be brought into a satisfactory state as long as insects are permitted to remain in the house.

Aviary in Greenhouse (*W. J. L.*).—We do not know of any contrivance by which the birds can be protected from smoke when the house is fumigated; but we have long had birds in a greenhouse, and with cleanliness by syringing and otherwise good culture we have succeeded in preventing insects infesting the plants, and rendering fumigation unnecessary. This is the best practice you can adopt. You would, however, find a fumigating case useful—a wardrobe-like frame, well made and covered with close calico or some other suitable material, and having closely fitting doors. In this case such plants as show Pelargoniums, Calceolarias, Cinerarias, and others subject to the attacks of aphides could be fumigated and the insects destroyed before the plants are placed in the house. Such a case, in which a few plants can be placed and fumigated as required, often prevents the necessity of fumigating a house, and a considerable saving of tobacco is effected.

Costmary (*W. Gleave*).—The leaves you have sent are of this old herb, which is also known as Alecost. It is the Pyrethrum Tanacetum of Linnaeus, and Balsamita vulgaris of Willdenow. The whole plant has a strong aromatic and agreeable odour, and a bitter warm taste, from which it has been regarded as a stimulant, and very energetic. It formerly enjoyed great reputation as an antispasmodic, and macerated in oil it formed oil of balm, so much used for applying to wounds, and particularly to contusions. It is a native of the south of Europe, and is an old inhabitant of British gardens. It was quaintly described and its uses recorded as follows by Parkinson 250 years ago:—"Costmary or Alecost is a sweet herbe, bearing many broad and long pale green leaves, snipped about the edges, every one upon a long foote-stalke; among which rise up many round greene stalkes, with such like leaues on them, but lesser up to the toppe, where it spreadeth it selfe into three or foure branches, every one bearing an ymhell or tuft of gold yellow flowers, somewhat like unto Tansie flowers, but lesser, which turne into small heads, containing small flat long seede: the roote is somewhat hard and stringy, and being diuided, is replanted in the Spring of the yeare for increase. Costmary is of especial vse in the Spring of the yeare, among other such like herbs, to make Sage Ale, and thereupon I thinke itooke the name of Alecost. It is also vsed to be put among other sweete herbes, to make sweete washing water, whereof there is great store spent. The leaues haue an especial vertue to comfort both the stomack and heart, and to warme and dry a moist braine."

Imported Orchids (*S. M. D.*).—We cannot better reply to your question than by publishing the following from Mr. B. S. Williams's "Orchid-Growers' Manual," a work which you will find of great use:—"When unpacked these should have every leaf and bulb sponged over, and all the decayed parts re-

moved. There are many insects that harbour about them, such as the cockroach, and different kinds of scale, which are great pests. When clean they should be laid on dry moss and placed in some part of the Orchid house, where they are shaded from the sun. After a week or two pot them, or put them on blocks. Water must be given very sparingly at first, as it is liable to rot them; too much of either light, heat, or moisture at first is very injurious. The moss or peat should be gradually moistened, and when they begin to grow and make roots they should be potted, or put on blocks or in baskets, but care should be taken not to have the pots too large, overpotting being dangerous. As soon as the plants begin to grow those which come from the hotter parts of India should be put at the warmest end of the house, but they should not have too much moisture when first starting into growth: those which come from the more temperate regions should be kept in the coolest part of the house, and they should not be allowed to stand under drip, as this frequently rots the young shoots as soon as they appear. Such plants as the species of Vanda, Saccolabium, Aërides, Angraecum, Phalaenopsis, &c., I place so that the heart or crown hangs downwards in order that no water may lodge about them. They should hang for about a fortnight, and may afterwards be put on blocks or baskets with moss; but they must have but little water until they begin to grow and make new roots, after which they may be treated in the same manner as established plants. This is much the safest mode of treating these valuable Orchids on their first arrival in this country." The price of the book is 7s. 6d., not 5s., as we inadvertently stated a short time ago, and which we quoted from an older and smaller edition.

Names of Plants (*E. B. W.*).—1, The fronds appear to be those of Adiantum hispidulum, but are small for that species; 2, Specimen insufficient for identification, but it resembles Aspidium aculeatum; 3, Selaginella caesia; 4, S. Wildenowii; 5, Hebeclinium lanthum; 6, Stapelia hufonis. (*R. Masters*).—Diplacus glutinosus. (*H. Begbie*).—1, The specimen sent was scarcely sufficient for identification, but it appears to be a large form of Campanula rotundifolia; 2 is Hypericum perforatum. (*F. C.*).—Owing to the specimens having been packed in cotton wool they were so shrivelled as to be unrecognisable. (*G. D. C. T.*).—We cannot with certainty identify the specimen, but it resembles Sedum altaicum. (*A Reader*).—1, Asplenium longissimum; 2, Asplenium dimorphum; 3, Cyrtomium falcatum; 4 and 5, Insufficient for identification. (*C. F.*).—Both specimens were greatly crushed in transit through the post-office, but the one with yellow flowers is apparently Chrysanthemum bipinnatifidum. (*G. P., Hunts*).—1, Leycesteria formosa; 2, Lavatera arborea flore-pleno; 3, Eupatorium purpureum.

POULTRY, PIGEON, AND BEE CHRONICLE.

THE CROSS-BREEDING OF SHEEP.

(Continued from page 198.)

HAVING described the various pure breeds of sheep, without which crossing would be comparatively unprofitable, we now propose to allude to the plans and systems adopted by the most eminent agriculturists in improving and establishing those breeds which stand highest in estimation, and also to consider the means we have for raising animals of a style and character distinct from those we possess at present. We will take first the Hampshire and West County Downs. The native breeds in both Hampshire and Wiltshire were originally horned white-faced animals. They were large, coarse, flat-sided, but hardy sheep, well suited for folding on the hills. These horned Hampshires were crossed with the South Down nearly or quite one hundred years ago; but the Wiltshires were not often crossed, but exchanged for South Downs somewhat later, for it occurs that the last flock of these horned sheep were seen in the year 1819. Be this as it may, both the Hampshires and Wiltshires as Down sheep were coarse animals, the former being the worst, and showing less of the South Down character than the Wiltshire. Neither of the breeds showed any improvement worth notice until about the year 1830, when Mr. John T. Twynam of Winchester used the improved Cotswold ram with his Hampshire ewes, and the result of the first cross gave a strong proof of the preponderating effect of the male animal. This cross gave by careful selection of the darkest-faced and best sheep a valuable opportunity for the breeders in both Wiltshire and Hampshire to improve their flocks, and some of them did so by the purchase of rams from Mr. Twynam's flock. It may be fairly inferred, that although special circumstances occurred to prevent Mr. Twynam from carrying out his original object of establishing a cross breed of a type and character similar to what has since been done in the Oxford Down, yet it

effected a great improvement in the flocks in both counties, the animals yielding more wool, having a greater aptitude to fatten, and producing a greater number of twin lambs. The next improvement in connection with the Hampshire or West County Down breed occurred through the intelligence and perseverance of the late Mr. William Humphrey, of Oak Ash, Chaddleworth, Berks, specimens from whose flock were often prizewinners at the Royal Agricultural Society's meetings. It may be stated that it was these splendid sheep which induced the Royal Society to admit into their prize list the Hampshire or West County Down. These had previously been exhibited in the short-woolled classes with a variety of others, and we recollect at the Chester Meeting of the Royal Society that this stock as shearlings exceeded all others.

The method adopted by Mr. Humphrey in establishing the type of his improved Hampshire Downs was as follows. He has said, "I received my first impression of the desire to improve my sheep through noticing the manner in which the Cotswold breed had been improved by crossing with the smaller Leicester breed, and the most robust animals of the produce being selected for use; the thought then struck me that my best plan would be to obtain a first-rate Sussex Down ram to put to my larger Hampshire Down ewe, in order that I might improve the quality and form of flesh, still retaining the size and hardihood so necessary for folding on our cold and exposed hills. In consequence I applied to Mr. Jonas Webb, who sent me a shearling by his favourite sheep called Babraham, and for two years I selected for myself but did not use them, as they did not suit me so well. I then commissioned him, without regard to the cost, to send me his sheep which obtained the first prize at the Liverpool meeting of the Royal Society; and from the first and the last two sheep—by marking the lambs of each tribe as they fell, then coupling them together at the third and fourth generation—my present flock was made, not having used any other blood on the male side for more than twenty years. I found some difficulty at first when putting the first-produce ram to the first-produce ewe, the lambs coming too small to suit my customers. To obviate this difficulty I drafted out the smallest-bred ewes, replacing them with the largest Hampshire Down ewes which I could meet with that suited my fancy, still continuing to use the most masculine and robust of my rams to keep up the size. Some of my friends advised me to use a large coarse sheep to the smallest ewes to remedy the defect, but the larger ewe seemed to me the better way, and that course I pursued, and the using of no male animal but my own, the pedigree of which I was acquainted with for more than twenty years, has succeeded beyond what I could have expected." Now, we recommend all parties intending to raise a new breed by crossing to take particular notice of Mr. Humphrey's mode of procedure, because we consider it not only based upon sound principles, but because it has the further recommendation of his great success.

As an improver of the Wiltshire Down breed, originally descended from the Sussex Down, we must introduce the name of Mr. James Rawlence of Bulbridge, near Wilton, who says, "I commenced improving my flock by drafting all the small and delicate ewes, and the remainder were crossed with rams of the Hampshire breed. I bred from their produce for some years, and then had another cross with the Hampshire, still continuing to cull defective ewes. After I had obtained considerable size from the infusion of the Hampshire blood I had recourse to some rams bred by Mr. Humphrey of Chaddleworth, Berks. I use my own rams, and I also frequently purchase a few of the best Hampshire ewes I can get, put my own sheep to them, and use their lambs. I also put a sheep of Mr. Humphrey's to some of the best of my ewes, and select rams from their produce, thus getting fresh blood without making an entire cross." Mr. Rawlence's great experience and success renders his observations worthy of great attention and consideration by flock-masters in general.

We must now give the particulars and origin of the celebrated new Oxford Down breed, which has been recognised by the Royal Agricultural Society as an established style and type of sheep, and included in their prize list within the last twenty years. These large and beautiful animals, of which the late Mr. Samuel Druce of Eynsham, Oxon, was one of the earliest and most successful breeders, says that "the foundation of this class of sheep was begun here about the year 1833 by using a well-made and neat Cotswold ram with Hampshire Down ewes. At the same period several breeders of sheep in this neighbourhood also tried the experiment, consequently there has always been an opportunity of getting fresh blood by selecting sheep which suited different flocks, and thereby maintaining the uniform character which is now established." Mr. Druce adds, "With ordinary skill in sheep-farming I find no difficulty in keeping the form and size of the

animal as it should be, the wool of a valuable texture, and the carcass not deficient in quality; and I maintain that the good qualities can be better secured by employing the cross-bred animals on both sides than by confining the practice to the first cross." Mr. Charles Howard of Biddenham, Bedford, has also been a very successful breeder of the same class of sheep, and following pretty much the same method of obtaining it as that pursued by Mr. Druce. This breed of sheep now ranks very high in the estimation of farmers, particularly in the midland counties. In referring to the Shropshire Downs, which although of mixed origin have also been admitted into the prize lists, and to some extent may be considered rivals of the Hampshire and South Down stock, have unquestionably sprung from an original and local breed called the Morfe Common sheep, a locality near Bridgnorth, for a long time, in consequence of their being crossed with not only the long-woolled Leicesters and Cotswolds, but also the short-woolled South Downs. The admixture of such different blood prevented such a uniformity of type as was desirable; but as the system advanced in sheep-crossing they have been improved, so that they are also admitted into the prize list of the Royal Agricultural Society; and at the Chester meeting, where they were shown with other breeds, they were distinguished by receiving the prizes as older sheep when they had no chance against the Hampshires as shearlings. These sheep still vary more in character and style than any other recognised breed, but Lord Chesham has done more to fix a type for them than any other breeder.

Now, after having related matters as to the characteristics of certain breeds it is a question of great importance, and may be made valuable by the selection of rams of certain breeds for crossing the off-going ewes or the last year of breeding for the sale of lambs or tegs for slaughter, and for this purpose the Oxfords offer a better alliance than the long-woolled and white-faced breeds, because the butchers prefer sheep with dark faces, as they are sure to die with more internal fat, making also a higher price at a given weight. We will now give a few of our opinions relating to the possibility of raising a new breed, and possessing in our opinion some valuable qualities beyond either of our types at present in existence. Having been accustomed for many years to the rearing of lambs bred from the horned ewes, both of Dorset and Somerset, produced by a cross with a Down ram, we have often thought if a breed could be established of this cross how desirable it may be if carefully carried out. We have been led into this way of thinking because many years ago there was a little movement in this direction made by some of the Dorset and Somerset breeders, who thought that they may give up the idea of horned sheep and obtain all the advantages they required from a Down breed; but they soon found that the Downs would not lamb early, even in their climate and soil, where the horned ewes had always done so. They also found that the horned ewes leave a superior fold of manure for the food consumed compared with the Downs, and that they could not raise enough lambs from the Downs. Some farmers tried the first cross, but they were not continued. We have purchased this cross in two instances, and they answered an excellent purpose—lambing early in December with plenty of twins, and the ewes being excellent mothers furnished the best quality of lambs at Easter. In the endeavour to establish a fixed character and type between the horned ewe and Hampshire Down we should select the former of the best class, like those bred by the late Mr. John Pitfield of Higher Eype, Bridport, Dorset, whose stock is still maintained in the county, his rams having been much sought for. These ewes being well-woolled, short-legged, long, deep, and round in the body, also yielding the greatest number of lambs, and being capable of becoming fat during the time of rearing their lambs, which they make of the best quality, would in our opinion if crossed with the Down produce a breed having all the qualities which can be required if carried out as recommended by Mr. Humphrey, and would well repay after some years any farmer of sufficient experience and perseverance who would not hesitate about the trouble and expense.

WORK ON THE HOME FARM.

Horse Labour.—In some of the early districts harvest work will be forward enough for the horses to be employed on the land in various ways; some of them will be engaged in preparing the land for sowing with *Trifolium*, Vetches, &c. After sowing the seed of these green crops upon the cleanest fields, and those requiring the least labour in preparation, some work may then be undertaken on the land called autumn cultivation; but steam power should be made to precede the horse labour, not only because so much more work can be effected within a given time, and more effectually performed, but also because it relieves the animal power of the farm, whether horses or oxen, of the heaviest work. This is a matter of no small importance when

we consider the cost of the food of the working animals, and as far as horses are concerned the yearly depreciation in value also. For a fortnight past, and as soon as the Wheat crop had been carried, we have noticed the double engines steam tackle at work on some farms, very much to the credit of the managers, whether they are on a home farm or occupiers as the tenants of the land. This is taking time by the forelock, and on the same farms last spring we noticed the steam power at work, which forwarded the seed time so much that we now see these fields covered with splendid root crops seeded in due season, as well as fine crops of Barley sown after Wheat. The autumn work we are now recommending could not be done last year to any extent in consequence of the lateness of the harvest, thus leaving a legacy of labour for the present year. There is, however, every appearance of this season continuing favourable for all work required upon the land. Upon the strong and heavy lands preparation for the Wheat crop seeding should not be much longer delayed. Whether the preparation is by the long fallow or after fallow crop, such as Beans or Peas, the land cannot be tilled too soon after the crops are cleared and the manure carted upon the land so long as the weather continues favourable, after which artificials may be sown broadcast and ridged in, or the manure may be applied in the spring. Where the strong lands are put into Wheat out of Clover lea the manure should now be laid out and the land ploughed and pressed, in order that it may become mellow before the seed is drilled; and we must again call the attention of the home farmer to the policy of wide drilling, so that in the spring the ordinary three-shared horse hoe may be effectively employed between the rows; for upon cold strong soils in some seasons the Wheat plant will lose colour and look sickly and yellow, in which case nothing changes the colour of the plant like effective moving of the surface by the horse hoe. The plan of hoeing with the machine, which does the width of the drill at one operation, is by no means suited to the hard surface of the land in winter-sown Wheat, although it does very well upon spring-sown Lent corn, the soil being loose.

Hand Labour.—This will still be required for drawing straw for thatching corn and pulse ricks, the second hoeing of some late root crops which may have been neglected during the harvest, filling and spreading of manure, and hedge-trimming. In the later districts the men will be engaged for a little time yet in cutting and tying the grain and pulse crops, and on such farms all roots should be sown early, so as not to require any attention by horse or hand hoeing during the harvest. The early crops of Turnips are so fine this year that they are now fit for feeding by the sheep, and, in conjunction with a run on the Clover and Saintfoin leas they may be folded at night on the roots, receiving some little cake or corn as the weather and objects for which the sheep are kept may dictate. If sheep are intended to be fattened for the Christmas markets it may be desirable not to allow the sheep to run into other grass keeping, for after they get accustomed to the root food they do best to remain on the land and have a small fold twice each day with half a pound of cake or corn at first, but further on in the season they may have one pound each sheep; but they never pay for more, because they cannot properly assimilate a larger quantity, or turn it into profitable meat. As the root crops are so abundant the milch cows may have some Turnips drawn on to the pastures as supplementary to the grass food. If, however, a butter-making dairy is kept the root-feeding should be omitted, and cake or corn added where the grass is short. When the root crop is abundant like it is now at least one-third of the crop may be pulled and carried away, two-thirds of a full crop being quite enough for consumption on the arable land with cake where a corn crop is to follow. Now is the time for the home farmer to consider his position as to obtaining the cattle for stall or box feeding during the winter; but where there is a good sale for milk, or where it is convenient to obtain calves for suckling, milch cows with calves at foot will pay more money than fattening bullocks, especially if the cows are kept to the stalls and receive the same allowance of food as the fattening cattle. In that case the cows if well bred, either Devons, Herefords, or Shorthorns, will feed out fat, although they may give a profit in milk or in suckling calves for veal. The ewes in lamb must now be looked to very carefully, and care taken that whilst food is so plentiful as now that they do not get too much forcing food; and whether the stock is horned Dorset ewes—now getting heavy in lamb—or late-lambing down or cross-bred ewes, they may be kept too high, and suffer at lambing time in consequence if they make fat internally during pregnancy.

THE POULTRY YARD IN SEPTEMBER.

WE are apt to think that our poultry yards require no attention while fine and dry weather, such as we have had for the last fortnight, prevails. This is by no means the case. We have found sickness particularly liable to appear and spread during dry summer time. The cause of this is somewhat doubtful. It may be that in the absence of rain to wash the soil it becomes foul and tainted; at this season, too, we are apt to have our stock at its highest numbers, which of course contributes to the same evil. Thinning should be continued as fast as possible, and lime-washing freely resorted to, even well-kept houses become offensive in summer without it. Chickens which cough should be separated from their fellows, well fed and stimulated till quite cured.

Sneezing and coughing are often the first signs of a want of tone in the system, which if neglected may terminate in roup, but which, if taken in time, passes off very rapidly. In most places growing chickens suffer now from the decrease of insect food; old birds too are going, or soon will go, deep into the moult, and all will be better for a tonic. We have long used one, when occasion required, taken from the pages of our old friend "The Henwife," and always find it efficacious.

"One pound of sulphate of iron, one ounce of sulphuric acid, dissolved in a jug with hot water; let it stand for twenty-four hours, and add one gallon of spring water. When fit for use, one teaspoonful of the restorative to a pint of water, given every other day to chickens, and once a week to old fowls, will make roup and gapes entirely a stranger to your yards."

Chickens hatched at this season are generally delicate, and seem to pine from unaccountable causes. If it is desired to rear any, we have found it best (save in the case of Bantams) to let them live the most natural life possible. We have some ourselves doing admirably. The hen sat herself in a hedge, and has from the first ranged with the chicks at complete liberty, taking them back every night to their dry birthplace in the bank. We suspect that some of the mysterious maladies which beset summer chickens may be attributed to the foul air of coops, and the ease with which the soil, as we have before said, now becomes soured, if they are kept long on the same ground.—C.

CANARY TREATMENT IN OLDEN TIMES.

I HAVE before quoted from an old work treating upon Canaries, and I here give a chapter showing forth their "dispositions and inclinations." The writer, Mr. Hervieux, says—

"It may truly be said that almost all Canary birds differ in their temper and inclinations, but being afraid it would take up too much time to distinguish between them all successively, I think fit to divide them into four classes. In the first place I find some cocks who are always of a melancholy temper, and if I may so call it, thoughty, who sing but seldom and in a doleful tone, being for the most part huffed up. This sort of Canary birds seldom answer the end they are designed for, for if you would teach them to sing flageolet tunes they are a prodigious time learning, and are never perfect in what they have been taught; besides that, what they have learnt they easily forget, especially the first time they come to be sick, as at moulting time or the like; and sometimes there are such as pine so much at being always covered that they die, and this sort of Canary birds, though they are cocks, I believe would never sing unless they were put to it under other old brisk Canary birds, that hearing them continually sing they may in some manner serve them instead of masters. These same birds are sometimes naturally so slovenly that their feet and tails are always very dirty. When you would clean them without danger you must use the following precautions:—Take the Canary birds into your hand, and with a little spittle by degrees take off the hardened filth that sticks on their feet which often hinders them from perching, and it often happens that when care is not taken to clean them their feet grow sore and their claws drop off. If you will make use of water instead of spittle to clean them it must not be cold, unless it be in very hot weather, for besides that the cold water does not clean them so well, there is danger that it may kill them through coldness striking to them on a sudden, especially in winter. Some young curious persons have lost their Canary birds by using of cold water at a time that did not seem to them cold enough to warm it, and your hands ought to be hot when you take hold of the bird."

As evidence that Mr. Hervieux estimated his mode of treatment at some considerable value, he says, "All the particulars I take notice of in this small treatise are of such consequence that those who through ignorance or negligence do not observe them lose many of their Canary birds, for those little creatures are of so tender a constitution that a very small matter impairs their health and occasions their death. On the other hand, if you design to have this sort of Canary birds to sit there is not only reason to believe that their young will be no better than the old, but the first cross accident that happens in their breeding, as the death of any of the little ones, or any distemper of the hen, or any other thing of this sort, they grow melancholy and dull that they often die; or if they happen to survive it they are all the rest of the time they remain in their huts so heavy that they never cheer the hens by singing, especially when they perceive the young begin to hatch. I would advise those who have any of these to get rid of them to save themselves the concern it will be to them to see that whatsoever they can do for them nothing will succeed.

"There are other cock Canary birds so mischievous that they kill the hens that are put to them; but sometimes it happens that those cocks have some other qualities which make some amends for that fault; as for instance, they sing very sweetly, have very fine feathers, and are very familiar, therefore there is no need of getting rid of them since they have good qualities to recompense for the bad. Besides, if for want of another cock you are resolved to have a breed from them you may do it as I will here prescribe." The writer's system of preparing a couple of hens to place to one cock bird is practically good, but although his particular system has long been adopted by most of the London fancy breeders, still I prefer the mating of only one hen to a cock bird if for breeding with in a cage. However, here is his plan:—

"Take two very strong hens, and if possible let them be a year older than that mischievous cock you design for them; put these two hens sometimes together into the same cage that they may grow very well acquainted, and by that means not grow jealous and fight when they have but one cock between them. A month before they are put up in order to sit they are both to be turned into the same hut, and when the proper time for coupling is come put in the cock to the two hens; he will be sure to beat them, especially during the first day he is with them, but both the hens joining to defend themselves against him, they will at length gain an absolute ascendancy over him, so that he, perceiving he can gain nothing upon them by force, he will in a little time grow so familiar with the two hens as to gain them by kindness, and thus these weddings by force often prove more successful than others, from which great hopes were conceived, and in the end came to nothing or very little. I have taught this way of coupling mischievous Canary birds to some who have owned that it has proved successful."

The above method is very good when matters run smoothly, but in seven cases out of ten when two hens are placed in a cage with one cock bird one of the two becomes a favourite, and this leads to jealousy. If one hen should obtain a choice scrap of building material in the shape of a spray of moss or a feather the other hen will not rest until she obtains it, and this leads to unpleasantness in the household. The nests thus often become damaged, and in the hens' eagerness to protect their respective building places I have not only seen the entire nests dragged out, but also the eggs scattered about the cage.—GEO. J. BARNESBY.

VARIETIES.

THE ENGLISH HARVEST.—We have, says the *Agricultural Gazette*, been privileged with a glorious commencement to our English harvest, and we have some reason to hope for a continuance of the same favourable conditions. It happily does not always rain here; and the longer a tolerably fine season is overdue the more likely is its immediate arrival to be. We may encourage ourselves by remembering that we are now entering upon the most settled period of the year, when dewy mornings, bright days, and cooler and keener air prevail than in the dog days. Over the southern counties harvest is rapidly drawing to a close. In many places the Wheat has been garnered, and a little late Barley or Oats is all that remains out. In the midlands rapid progress is being made, and in the north the splendid weather which has enabled south country farmers to secure their crops has been filling ears of corn beyond the hopes which farmers dared to cherish a month ago.

— **PREPARING FOR ROOT CROPS.**—The same paper observes that the next three months is the season for laying the foundation for heavy crops of Mangolds, Potatoes, and Swedes in 1881. Now is the golden time for steam cultivation, for ripping up stubbles—cultivating, cross cultivating, and dragging them—getting off couch and turning it. Much of success in farming matters depends upon taking time by the forelock, and performing every operation rather before than after its recognised season. The early worm can do but little injury to the early crop, and the early farmer is the man to meet times in which late and lazy men have no chance.

— **FOOD PRODUCTION IN AMERICA.**—One of the strangest cases of speculative discomfort, says the *Prairie Farmer*, is the fear expressed by some that there will be an over-production of food in the United States, and that such over-production will lead to financial embarrassment. It is true that the Dutch, upon gaining possession of the Spice Islands, cut down a large portion of the spice-yielding trees in order to enhance the value of what remained. On this

principle some croakers would have us kill off half our cattle and burn half our crops before reaping, or what would be about the same thing, refrain from raising more than one-half of what our soil and industry are capable of producing, lest, forsooth, there be a plethora, a glut, or an over-production of bread and meat, and food be a drug in the market! Nonsense. There is no such thing as over-production, and in articles of food even the appearance has not been presented. The American people are the only ones in the world now, or in the history of the world, that have had enough to eat. The Germans have not enough to eat; they cannot get it. The French have not enough to eat; they stint themselves. The English have not enough to eat, but try to supply the want by the use of cheap beer. The Irish certainly have not enough to eat and never had. The people of Asia are all on the brink of starvation. The people of Africa make cakes out of mosquitoes. The tribes of South America fare no better. With ninety-nine hundredths of the people of the world insufficiently supplied with food, what nonsense it is to talk about an over-production of breadstuffs.

— **NEW HOPS.**—Two pockets of Hops, the first of the season in this district, were sold to a resident at Hereford on Tuesday at £12 per cwt. They are the earliest pick on record in that neighbourhood, and are of an exceptionally superior quality for so early a gathering. The Hop crop promises to be one of the finest known for years.

— **MORTALITY OF CATTLE FROM AMERICA.**—Referring to this subject a correspondent makes the following remarkable statement:—Out of 375 cattle shipped for England in the "*J. C. Stevenson*" 357 died; 175 were shipped in the "*Glendawe*," and 157 died; 266 were shipped in the "*Canopus*," and 219 died, the cause being attributed to the rough weather in the Atlantic at that time; but he further states that during the late calm weather the "*Edward*" lost 30 out of 130 cattle, and the "*City of Bristol*" 127 out of 460, which is attributed to improper stowage and defective ventilation.

— **HARVEST PROSPECTS IN SCOTLAND.**—The Leith correspondent of the *Mark Lane Express* writes under date August 28th:—"The harvest makes rapid progress all over Scotland. [In the Lothians and in the adjoining counties much has been cut down] during the past week, and a considerable quantity carried and stacked in safety. Some small portion of the Oat and Barley crops has also been thrashed and brought to market; the samples, however, can scarcely be reckoned as fair representations of either crop. [Oats were generally of good colour, but some of the lots gave evidence of too rapid ripening, and therefore showed a somewhat shrunken or shrivelled appearance. Barley.—The two sample sacks shown in Edinburgh Market on Wednesday were high-coloured and rough though of good weight; but these do not represent the crop properly, as there will be much fine-coloured and weighty Barley; but there will also be a considerable portion of secondary colour and quality. Wheat promises well, but that crop does not come on so quickly as either Oats or Barley. There will be good quality and an excellent yield, perhaps a full average. Potatoes still promise largely, and, though the disease does exist, with fine dry weather for the next three weeks we hope to hear little of it. The yield will be large, and if disease keeps off will probably range from 8 to 12 tons per acre. Turnips are irregular, but there are many fine fields in the Lothians, Stirlingshire, Perthshire, and Fife—except, indeed, the 'East Neuk,' where so little rain fell.]"

UTILITY OF DRONES.

A SMALL pamphlet on "Bee-keeping for Amateurs" from the pen of Mr. Thomas Adley of Epworth has been published lately. I am not going to review the work of Mr. Adley here further than to say that it might be improved by revision and correction. The neighbourhood of Epworth has many bee-keepers, and Mr. Adley collects hundreds of swarms of condemned bees every year, and sends them to bee-keepers in all parts of England who want such to strengthen their own stocks and for feeding into stocks. I think no other person in England has saved with his own hands more bees from the brimstone pit than Mr. Adley has. "Drones," says Mr. Adley, "are male bees, and are necessary to a prosperous condition of the hive, not only for the fertilisation of young queens, but as a means of keeping up the heat of hives during spring when

early brood is hatching with fewer working bees than would otherwise be required. Thus many more workers can go abroad in search of honey and pollen than in hives which have not any drones. Afterwards, when the drones increase in number, they come out and fly abroad, which indicates that they are becoming stronger and are coming nearer the swarming point. As regards attempting to destroy drones it is a great folly to do so, as the bees know best how to dispose of them when no longer needed. When the principal part of the season for breeding has gone by, and the time has arrived for the storing of honey, the banishment of drones begins. Some seasons when drones become very numerous their destruction commences at an earlier period. When drones are seen late in the autumn it shows that there is some deficiency in the store of honey or that the queen is not fertile, or some other cause."

This quotation, containing as it does so many mistakes and inaccuracies, is enough, and long enough, for the intelligent readers of this Journal. The idea of drones being bred early to keep up the heat of hives when they have few bees is certainly new, but this novel and extraordinary idea is contrary to fact and reason. Drone combs are generally built on the outside edges of combs, and hence drones are not bred till the hives are nearly full of bees. Bees know better than Mr. Addey what is good for them, and avoid rearing drones in the early spring months when they are not wanted. Working bees are as good as drones for producing heat, and are otherwise more useful than drones. Again, in the banishment and destruction of drones the bees are guided by laws and conditions different from those of the pamphlet now quoted. In ordinary cases drones appear about the time of swarming, and are reared for the fertilisation of young queens. When this is accomplished they are of no use whatever in hives, and are considered by the bees worthless nuisances, and therefore they are destroyed. After swarming, when hives become full, drones are hated, as at the swarming season. In good seasons they are permitted to live till the end of the season, when the general drone massacre takes place. In seasons of scarcity and famine the bees, instinct with self-preservation, destroy both old and young drones hated and unhated. The useful and industrial part of the community is so far protected and preserved by the destruction of the lazy and useless drones.

The bees in this locality have this season been constantly on the borderland of starvation, and drone brood and drones adult have been at a great discount throughout. They have had a sorrowful time of it.—A. PETTIGREW.

COMB FOUNDATION.

I SHOULD not again trouble you on the subject of comb foundation but for Mr. Cheshire's keen remarks on page 201. I offered in my last an alternative as an excuse for the attempts made by Messrs. Cheshire and Raitt to strengthen foundation, it having been implied in "B. & W.'s" communication that such efforts showed that they had failed to succeed, while I affirm I have succeeded. I expressed my doubt that they had failed, but that a natural desire to meet the craving for novelty, or the desire to make the use of foundation really and in spite of careless handling effective (which would be a most meritorious result), had exercised their ingenuity. Mr. Cheshire has chosen to take the former branch of this alternative to himself, to which my observations by no means bound him, but he knows best why he identified himself with it.

In the second paragraph of his letter he says the first letter of mine puzzled him a little, but his second has brought a solution. May I ask what puzzled him? He says later on, "Mr. Procter rightly supposes that experimentally I know nothing of breakdown." Is it that anyone except Mr. Cheshire has had the same experience? Is this the puzzle? Has Mr. Cheshire a monopoly of success, and has he been raised up only to supply the deficient intelligence of the vulgar multitude on apian matters?

Now with regard to his remarks on my veil and the solution it offered to my former letter, I beg to inform Mr. Cheshire that for nearly forty years I have been a progressive bee-keeper. I never smothered a swarm. I have passed through all the stages of advance—through collaterals, nadirs, Pettigrew's, &c., until I reached the climax: not, I confess it (yet unattained), of Mr. Cheshire's ultimatum, but of what I have found both successful and profitable. Now being something more than a sexagenarian it might be deemed excusable that with veil and without spectacles I should mistake a new outside comb (not a month before a plain foundation, when filled throughout and sealed as white as any pure honeycomb) for the latter until a second glance showed me the difference; and I beg to inform Mr. Cheshire

that my former "puzzling" letter had reference to facts not seen through my veil, and that I maintain, as he himself admits, that plain foundation properly handled is as safe to use as any ingenious appliance can make it.—GEORGE A. PROCTER, *Clk.*

OUR LETTER BOX.

Red Game Bantams (*C. D. A.*).—The cock should be snake-headed; his wings carried up, and close to his body; tail moderate, and rather drooping than otherwise. The hen should be small-headed, straight-combed, with wings carried close. She should be very dark brown, almost black, with golden hackle. Both should be hard-feathered.

Gapes in Chickens (*O.*).—Your chickens are dying of the gapes, and have the roup as well. Give to each chicken a pill of camphor the size of a pea, and put some lumps of it in every vessel from which they drink.

Fixing Foundation (*J. B., Sandal*).—Your plan of fixing foundation fixes too much. If the ends are not left free the stretching which working out the sheet by the bees involves would cause it to assume a wavy line. To prevent this, foundation sheets are cut about half an inch shorter than the inside of the frame. If you remove your worse than useless side supports your plan becomes an awkward form of Mr. Hooker's (for which see last issue), having also the disadvantage of occupying some space by wood instead of comb. There is plenty of room for ingenuity in these matters, but those who have no "practical" acquaintance with them are hardly likely to suggest better forms than those who have. Mr. Woodbury in his day was ahead of you, since he made the top bar to divide, by which he secured the advantages you claim, but escaped the defects we have pointed out.

REMARKS.

22nd.—Dull cloudy morning, fine bright afternoon and evening, beautiful moon-light night.
 23rd.—Dull cloudy morning, fine afternoon and evening.
 24th.—Rather cloudy and dull on the whole, though there was some sunshine in the afternoon.
 25th.—Dull, cold, and damp all day.
 26th.—Dull morning, cloudy afternoon and evening.
 27th.—Cloudy all day.
 28th.—Cloudy till 10.45 A.M., afterwards fine, bright, and very hot.
 A dull cloudy week with remarkably little sunshine, excepting Saturday, which was a bright hot day, the maximum temperature (82.6°) being the highest registered during the year, with the exception of May 26th, when a temperature of 85.0° was reached. The drought which commenced on the 9th still continues.
 —G. J. SYMONS.

COVENT GARDEN MARKET.—SEPTEMBER 1.

GRAPES continue to arrive in large quantities from the Channel Islands, the supply of home-grown fruit being yet limited. Plums are very plentiful, realising moderate prices.

LIFTING OLD VINES.

ANY gardeners are under the impression that old Vines are of no use, but only fit for the rubbish heap. I am quite aware that many old Vines are apparently in that condition, but some of them at least, I think, can be renovated. I have seen many Vines worn out at twelve years of age, and others not worn out at forty or fifty years of age. The reasons are easily told—overcropping, and not giving proper attention to the borders. But, it may be observed, there are Vines more than half a century old which bear large crops of good fruit annually, and yet have very little care bestowed on the borders. The reasons are, that the natural soil is very good or the roots are working in a drain, while the rods have not been over-weighted with fruit. I believe that if the natural soil is not good for Vine-growing the borders require renewing every twelve or fourteen years, and if they are both inside and out the work can be easily done without losing any of the crop.

The Vines here are between fifty and sixty years of age, and were in a miserable state when I entered on my duties thirteen months ago. All gardeners who saw these weak and scraggy examples said they were worn out and would never come to any good. But my employer not desiring to have fresh Vines, there was no alternative but to lift the roots, and that work was commenced at once. The borders were inside and out, not a root could be found within 3 feet from the surface in the outside border, and those were few and as black as burnt sticks, destitute of fibres. The crop was cut as soon as possible, and we commenced lifting the roots towards the end of September whilst the foliage was on the Vines. The weather at the time was dull, so that it was seldom necessary to shade the roof; had the weather been bright shading would have been imperative.

We commenced with having a quantity of turf cut about 3 inches in thickness, and to every cartload was added one bushel of inch bones with a good sprinkling of old lime rubbish and charcoal dust; but it was mixed as the border was being made, as the soil was used in turves. We cut a trench 7 feet from the Vine stems to the depth of the border, and worked the soil back from the roots. It was very tiresome work, the soil being very hard and stiff quite to the stems of the Vines. As the soil was removed from the roots they were covered with damp mats. No more soil was removed than could be replaced in a day. We placed at the bottom 18 inches of brick rubble sloping to the front, then a layer of turves with the grass downwards, and built a wall of turf at the outside. The

border was filled up to within 10 inches of the top, when the roots were laid out, the ends being cut clean with a sharp knife, and the roots notched at intervals. They were then covered with 10 inches of the compost, having it rather fine about the roots.

The house was closed when we commenced operations, and kept so for about three weeks, and the Vines were syringed three times a day. Air was afterwards admitted freely, and with the help of a little fire heat the Vines ripened their wood and foliage well. The inside border, in which there were a few roots, was kept moist during the winter to keep these roots fresh. The outside border was protected with straw during the winter.

When the Vines were pruned they were cut to the best buds. The Vines were started gradually the second week in February, and broke evenly and well. After they had made 6 inches of growth they were kept at 55° as a minimum and 60° as a maximum temperature, so as not to exhaust the rods of their stored-up sap. About this stage they commenced to emit clusters of quill-like rootlets from the old roots, which had callused over in the autumn. The shoots were not stopped till they had produced five joints beyond the bunch, and the top shoots were allowed to extend freely. At this time the inside border was kept well supplied with liquid manure.

We left a good number of bunches on the Vines as we could not lose a crop. The result is, that the berries have swelled to a much larger size than they were before, and the new border is full of roots for future work. These roots are on the top of the border, which was watered as required, and the inside borders have been well supplied with liquid manure. On two Vines young canes had been run up previously, and the old rods were cut out at pruning time. These young canes did not show fruit so well as the old rods, but the bunches and berries are much larger and better coloured. Although we lifted the Vines we have not only not lost a crop, but have, on the contrary, secured one far superior to that of last season, and we have a supply of well-finished and good family Grapes.—A SOUTHERN GROWER.

[We saw the Vines referred to last year, and they were indeed "miserable." We have seen Grapes produced by the Vines this year, and they are excellent. We congratulate our correspondent on his well-earned success.—EDS.]

POPULAR GREENHOUSE FLOWERS.

CINERARIAS AND CALCEOLARIAS.

ALTHOUGH there is an abundance of what are generally termed florists' flowers, and annuals more or less suitable for culture in pots, the number of really popular and serviceable kinds is somewhat small. With this limited selection, however, it is really remarkable what a display can be maintained all the year round with but poor convenience for the work, and at a comparatively small outlay. At the present time we have Balsams, the strains of which are now of the best description. Cockseombs, Celosias, and Torenia Fournieri in the way of annuals; Zonal Pelargoniums, both single and double flowering, many of which produce immense trusses; and Fuchsias in bountiful variety, with a good batch of Gloxinias and tuberous-rooted Begonias. These relieved with a few Ferns, Selaginellas, and spring-sown Panicum plieatum form a cheap and very effective display, while the

requirements of the plants are of the simplest description. Later on the young Cyclamens, Chinese Primulas, *Browallia clata*, *Salvia splendens*, Zonal Pelargoniums kept denuded of bloom and well exposed to the sun at the present time, Chrysanthemums, and late Fuchsias will be in beauty. To follow these there will be the old Cyclamens, earliest-flowering Cinerarias, and Salvias. These will be succeeded by late Cinerarias, *Primula amoena*, *P. verticillata*, *P. japonica*, and others of the hardier kinds; the earliest of the large-flowering or stage Pelargoniums, Calceolarias, Carnations, *Spiræa japonica*, Alpine Auriculas, and others. Then comes in the main batch of Pelargoniums and Calceolarias, more *Spiræas*, Zonal Pelargoniums, Lobelias, and Harrison's Musk, which carry on the display till the Fuchsias and other previously mentioned plants are in again. I am aware that this list is far from being complete, but the object of these notes is to show what can be inexpensively done with the aid of but little fire heat.

Where there is a conservatory to be kept gay, with a number of plant houses and pits in which to grow the requisite supply, the process of plant-growing is much simplified, but with the majority, and probably the most enthusiastic of cultivators, house room is generally of very limited extent. Yet, strange to relate, it is generally in comparatively small places that florists' flowers are to be met with in the best condition. Some of these growers have their specialities, others endeavour to grow all kinds of plants well. One instance of the latter—I could give several—I will mention by way of illustration. Visit when I will a hardworking friend of mine, there is invariably much to admire in the way of florists' flowers, all being done with the help of a small plant house, a small vinery, two pits, and a few frames, which in addition have to do duty in the way of growing Melons and Cucumbers and the raising and wintering plants for the kitchen and flower gardens. The majority of the above-mentioned plants are grown, and in addition a few Azaleas, Deutzias, Lilliums in variety, and *Vallota purpurea*. One great secret of this gardener's success is, that he works all the principal kinds in batches throughout, the plants thus receiving the requisite fair treatment, not being drawn up by and smothered with insects, oftentimes in undisturbed possession of the more advanced of the flowering plants. A varied arrangement is no doubt most pleasing to the non-professional, but the true florist prefers having his favourites massed together, and can see plenty to admire in the various forms, markings, and colours of the varieties. Where the batch system is practised, one kind has frequently to be turned out before it has really collapsed in order to make room for a successional kind, but it is often really imperative that this apparently sacrificial act should be performed, and florists' flowers too after they have reached a certain stage soon become unsightly and dirty.

Of the various kinds above mentioned, probably with one or two unimportant exceptions, Cinerarias and Calceolarias are the most impatient of fire heat, coddling, and mixing with other plants, especially when growing. Of the two the former are by far the most serviceable, and are besides remarkably showy, but not so conspicuously so as Calceolarias. The treatment necessary for both is almost identical, the principal difference being in the time of sowing, as the Cinerarias are sown at different times from April till the end of July, whereas August and even early September is early enough for the Calceolarias. It is possible to err by too early sowing in both instances, as to have the plants in perfection they must be kept steadily growing on from the time the seed germinates; and any check experienced, whether from becoming rootbound in the earlier stages of growth, or being too dry or too wet at the roots, if not fatal in effect will at all events be the precursor of an attack of red spider in the case of the Calceolarias and green fly on the Cinerarias. It will be found no easy matter to dislodge either of these pests when once established. Bright sunshine and a dry base, such for instance as the shelves and staging of a greenhouse, are injurious to both species, especially in the earlier stages of growth. A shallow frame on a bed of ashes, either at the north side of a wall or sloping northwards, will be found suitable; and when the plants are transferred to the greenhouse they should be placed on either a slate or a gravelled bottom, and only sufficient fire heat given to keep out the frost, or occasionally to prevent damping from excessive moisture.

It is now too late to make a sowing of Cineraria seed, as the plants obtained would not attain to a serviceable size. This is not the case, however, with Calceolarias, as if a sowing of these is made at once good-sized plants may be had from it for flowering next May. Those who may have plants of the former, or later on of the latter, either in seed pans, pans of pricked-out plants, or self-sown in the open, will do well to pot them off before they have become drawn and weakly, employing pots of a size so as to

avoid cramping the roots. The weakest plants potted into 3-inch pots should, when these are well filled with roots, be shifted into 5-inch pots, and the strongest potted into 4-inch pots be shifted into 6-inch pots, the latter being a very serviceable size in which to flower them. If larger plants are required some of the best of each lot may be shifted on into 8-inch or 9-inch pots respectively. Clean well-drained pots should be employed in every instance, especially at the final shift, and it is very important that the operation of repotting be performed before the plants have become much rootbound, otherwise premature flowering will be the result, much labour thus being lost.

A suitable compost consists of two parts of turfy loam made somewhat fine for the small pots, afterwards broken up roughly; one part of leaf soil, with an addition of well-decomposed cow dung finely broken; failing this other decayed manure may be used—road grit or silver sand, and a sprinkling of small pieces of charcoal. This mixture of certain kinds of soils is given as being suitable, but it is not absolutely necessary to adhere strictly to it, as very good Cinerarias are not unfrequently grown by those who are unable to procure turfy loam. Where such loam cannot be had it is very advisable to use more leaf soil, say two parts to three of the ordinary loam used, and also charcoal in good quantities, and failing this broken crocks. Drain the pots most carefully, commencing with a big crock over the hole, next placing a layer of coarse pieces round this, over which more finely broken crocks, and finishing off with a thin layer of moss. When potting place a layer of the roughest soil over the drainage, over this a little finer soil; work the soil evenly round the ball, and make it moderately firm, and finish off evenly, the centre being slightly the highest, and filling the pots only so far as to allow the depth of the rims for watering space. Very dry soil should not be used, as afterwards it is moistened with difficulty; neither should wet soil be employed, as this is apt to go together too closely. It is also very important that the balls be in a moist state when repotted, as if very dry it is impossible afterwards to moisten them without saturating, and subsequently souring the fresh soil. Care should be taken not to injure the roots when removing the old drainage, and also not to crack the very brittle leaves during the operation of potting.

When the plants are returned to the frames after each operation a watering should be given them, using a fine-rose pot and tepid water, and the frame should be kept somewhat close till they are re-established, afterwards giving air freely. Crowding the plants is especially injurious; every plant ought to be clear of its neighbour, as nothing shows off the bloom better than healthy unbroken foliage. If the plants have to remain in the frames till nearly their flowering times it is very advisable that they be placed on inverted pots, the ashes about them occasionally freshened by raking, water be given carefully without any splashing about, and air given freely on all favourable occasions. Frost must of course be carefully excluded. Occasional mild fumigations with tobacco will keep the plants free from green fly, and when near their flowering time they will be materially assisted by alternate waterings with liquid manure. If large plants of Calceolarias are required the growths may be pinched once or twice. Do not, however, pinch those plants that are to flower in small pots, nor the Cinerarias, whether in large or small pots. Calceolarias require their bloom heads to be lightly supported with sticks.

To ensure the germination of Calceolaria seed, first fill well-drained pans or pots with soil consisting of equal parts fine loam and leaf soil with some sand, make this firm and lightly cover with sand, then water through a fine rose, and in the course of about six hours sow the seed thinly and evenly, press it into the sand, and lightly sprinkle a little more sand over it. Select a cool shady place, place the pan on a bed of ashes under a handglass, or cover the pan with a square of glass until the seedlings appear, which they should be before any water is required. Do not water the seedlings overhead, but moisten the soil by dipping. As soon as the plants are large enough to handle prick them out about 2 inches apart in pans or pots, using soil similar to that in which the seed was sown, again place them under handlights, afterwards treating them as advised above.—W. IGGULDEN.

TOMATO CULTURE.

I WAS much pleased to see, on page 179 of the *Journal of Horticulture*, the advocacy of the extended cultivation of the Tomato taken up by so able a pen as that of Mr. Iggulden. There is no doubt that the relish for the Tomato is rapidly extending, but, perhaps, is more the result of the palate becoming accustomed to them, or I might say educated (for the relish for Tomatoes is certainly an acquired taste), than from the introduction of superior

varieties, although there has been a great advance in that direction of late years.

That the plants should be grown as single stems and disbudded of all laterals cannot be too often or too strongly impressed upon those who are about to start for the first time their cultivation.

As illustrating the results of the practice advocated by me in the Journal during the spring, I had thought of sending to the Editors a sample of those grown out of doors with all laterals removed, and I cannot do better than do so at the present time, when the subject has been so well treated by Mr. Iggulden.

The sample sent is one of fifteen plants trained diagonally at an angle of 40° against a low wall, and from which we commenced gathering ripe fruits in July. The whole of the plants are equally good with the sample sent, which is a portion of the plant. The lower part having yielded its fruits has been removed, also the top with but recently set fruits. The fruits are not so fine as those in the houses, but my object is to show that it is not necessary to stop Tomatoes after the first three or four trusses are set to insure a crop of ripe fruits out of doors in ordinary summers, although it is beneficial when, owing to bad seasons or other causes, the energy of the plant might be wasted for supporting late fruit that has no chance of coming to maturity.

The variety sent is a seedling of my own, which I have grown exclusively for outdoor purposes for several years.—R. CROSSLING.

[It is evidently a very useful variety. The fruit is large, rather corrugated, and terminates with a blunt apex—is, indeed, of almost the exact form of the Custard Vegetable Marrow. The crop is a heavy one—quite a rope of fruit, and admirably illustrates the value of the system of culture above indicated.—EDS.]

VIOLET ARGENTEAFLORA AND OTHERS.

THROUGH the courtesy of Mr. Lee, who sent me a bundle of plants in the spring, I have also been able to test the merits of his new Violet *Argenteaflora*. Like Mr. G. Abbey I have found it a continuous summer bloomer. Of course the quality of the flowers is not what one would be satisfied with in the spring. Still they are fairly good and very sweet and acceptable, coming as they do at a time when the scent of a Violet is a luxury often unattainable. *V. odorata pendula*, or New York, is the only other variety known to me from which one can generally gather a few sweet if not very presentable blooms even in summer.

Everyone who loves Violets and can spare a frame for its accommodation should grow this fine variety. Now is the time to make preparations for a supply of these delicious flowers through the autumn, winter, and spring. I find that it does better planted out in a cold frame than in any other way. The situation should be sheltered and slope slightly towards the south, so that every ray of the winter sun can be caught. The soil should be rich and light. If that universally recommended commodity, well rotted manure, can be incorporated with it so much the better. Chimney soot is also useful, and keeps away the worms. Take up the plants with a ball early in September and plant them in rows about 8 inches apart. Give a good watering, shade for a few days if the sun is hot, and they will at once make themselves at home and begin to bloom as if nothing had happened. New York will give you a good crop of fine flowers before the lights need be put on, which should be in October. Very little water is needed in winter, and as much air should be given as possible whenever there is no frost. After the first of the autumn bloom is over there will probably be a slight break in the supply, but New York even in the depth of winter never ceases blooming altogether, and in February comes again with a rush in all its soft splendour. My long frame last spring was very beautiful. The remembrance of it is a joy to the present time, and animates me in my present endeavour to secure a similar treat in the coming season. Few who have not seen it have any idea of the beauty and size to which a well-grown Violet attains.

The general run of the blooms of New York in spring are as large as a florin, perfect rosettes of a rich lovely mauve colour with white and red eye. I grew also a frame of *Belle de Chatenay*, with which I am delighted. This fine double white Violet is not an autumn or winter bloomer, but in spring I have found it to be more than equal to the raiser's description. I gathered many specimens which more than covered a halfcrown; they were pure white, and had the appearance of small white Roses. Each flower was sufficient for a buttonhole. I do not mean to say that every bloom is up to this mark; what flower is there that does not produce many inferior specimens for one good one? But this Violet produced last spring an abundant supply of good flowers, many of them magnificent, of the kind described. I have grown it ever since it came out. It must have the protection of a frame to do its best.

La Reine is also good with the same treatment, but the white is tinted with a dull purplish colour, which rather spoils its appearance.

Of the singles I can strongly recommend *Victoria Regina* and *Odoratissima*. These do well without any protection here.—R. W. BEACHEY.

THE FRUIT CROPS.

THIS year many fruits are sadly deficient with us, notably Apples, Pears, Walnuts, Filberts, Peaches, Nectarines, and standard Plums. Strawberries were a heavy crop, but many of the finest fruits were spoiled by the wet weather. President, Marguerite, and Sir Joseph Paxton were the most productive varieties of several grown here; and it may be noted that the oldest plantation (nine years) was the most productive, although I am aware that in some soils, particularly shallow light loam resting on gravel, Strawberries are nearly useless after three successive years' cropping. Marguerite is a first-rate variety, and I should advise anyone who has not grown it to give it a trial.

Raspberries, Red and Black Currants, and Gooseberries were excellent crops. The practice of mulching with well-decayed manure over the roots of the trees I believe to be a good practice. Plums on walls are a good crop, especially Kirke's Blue, Coe's Golden Drop, Jefferson's, Greengage, Victoria, and Orleans, but there are scarcely any on bushes or standards, with the exception of Diamond (a handsome Plum) and the Prune Damson. Anyone making a new plantation of Plum trees will find the last-named an excellent variety, and more reliable for bearing than many. The last three seasons old trees of this variety have been heavily laden with fruit. It is also an excellent plan to place a covering of decayed manure 3 inches in depth over the roots of these apparently old trees, so that the rains may wash the nutriment down to them.

Apricots have been an excellent crop here. More fruit has been taken from the trees this season than in the three preceding seasons together. The trees are on south and west aspects, but were equally good. When the fruit is all gathered the trees are examined, the dead wood cut out, all misplaced shoots and those not wanted are removed; those remaining that are required to keep up a supply of bearing wood are nailed in their full length, except at the top of the tree and where there is not room for extension, allowing plenty of room and light for each shoot. If the thinning-out is done with judgment the trees will neither require pruning or nailing in winter or the early spring months. Young shoots of Apricot trees that I saw nailed-in to the wall and pruned in the cold weather two and a half years ago were nearly all dead the following summer. That taught me to touch the trees as little as possible during the winter time, but to prune and regulate the trees after the fruit was picked. The short natural spurs produced are best left, as these often produce the best fruit, which ripens the earliest. If very few bees are about at the time of wall trees flowering, the syringe with a fine rose attached is employed for sprinkling the trees once or twice in the middle of the day. I think it helps to scatter the pollen grains.

Peach and Nectarine trees are a complete failure; the two past sharp winters with cold springs and with last year's unripened wood has left the trees in a sad plight. Some were killed outright—young newly planted trees as well as old trees. Of the young trees two varieties are worth noting as having withstood the climate better, and that is Barrington and Crawford's Early Peach. The last-named is an excellent, early, and handsome Peach. The only Nectarine I have with any fruit on is Hunt's Tawny.

Apples showed a plentiful bloom, but not one tree in twenty bears what can be termed a crop. Codlins that did not bear any or very little last year are good this. Hollenden Pippin is good, and has been so for the past three seasons, and a very useful Apple it is for dessert, lasting (if enough of them) two or three months—from November to the end of January. Ribston Pippin is scarce both on old and young trees. An Apple called Nonsuch has borne well the last two or three seasons as a bush. Nearly all kinds of Pear trees were deficient in bloom, consequently there is no fruit on them worth speaking of. Jargonelle has borne well against a south wall, and is in use at the present time. Doyenné d'Été is the best early Pear we have, being in use at the end of July or beginning of August, and very constant in bearing. Passe Colmar is bearing well this season, as it did last, against a wall with a south aspect. Williams' Bon Chrétien, Duchesse d'Angoulême, Autumn Bergamot, Forelle, Beurré Bosc, Beurré Diel, and Winter Nelis have very little fruit. Culinary Pears of Catillac and Uvedale's St. Germain are a thin crop.

Cherries, particularly Morellos, have a full crop, but the trees were very much affected with aphides early in the season; the

east winds prevailing so long when they were making their young growth checked it, and made it an easy prey to insects.—A. HARDING, *Orton Hall, Hunts.*

TROPÆOLUM SPECIOSUM.

I OBSERVE from a note (page 212) that this fine *Tropæolum* is growing and flowering freely at Richmond, and it is such a lovely plant that I daresay all who see it will desire to grow it. I have often found it most difficult to grow well. I have had plants direct from Scotland, and at the present time I have not one of them, all having started into growth feebly and then died. This has happened to plants in pots and beds alike. Why I cannot tell. I have grown it successfully elsewhere, but the soil here is lighter and hotter, and probably this is the cause of their failure. I should say a cool rather heavy soil, and a cool atmosphere, suits it best.—M. M.

THE NATIONAL EXHIBITION OF FRUIT AT THE ALEXANDRA PALACE.

SEPT. 3RD TO 7TH.

THIS, the chief Exhibition of the year solely devoted to fruit, was opened on Friday last, the entries being sufficiently numerous and the quality such as to constitute it a decided success. In a schedule of thirty-three classes, only three, comparatively of little importance, were unrepresented, and of the total amount offered in prizes—viz., £160, more than £130 was awarded. In some classes the entries were numerous, and altogether the competition was fairly spirited, the result being a generally satisfactory display. The arrangements were carefully and efficiently carried out under the superintendence of Mr. J. Forsyth Johnson, the only matter that seemed to require any alteration being the method of removing the prize cards to write the names of the winners upon them. Had the system followed by the Royal Horticultural Society's officials been adopted it would have facilitated the work and reduced the possibility of mistakes occurring in affixing the awards to the exhibits.

Collections of Fruit.—As was indicated in a note at page 212 of the Journal last week, the chief class provided in the schedule, as regards the money value of the prizes, was that for twenty varieties of fruits; £15, £10, and £6 being offered respectively as the first, second, and third prizes. We felt somewhat curious to see with what different interpretations the exhibitors would accept the wording of the schedule which did not restrict the number of varieties of one kind to be staged in a collection. Four competitors appeared, all staging good examples of the most important fruits, well selected and fairly answering what was probably the object of the class—viz., a diversified and representative collection of the chief kinds of fruits in general use. The coveted position of first was accorded to Earl of Harrington (Mr. J. H. Goodacre), who had excellent samples of fruit; but Grapes were represented by no less than six varieties which, had they not been of such good quality, would have somewhat injured his chance of success, especially as at least one of the competing collections contained more diversity combined with general good quality, though not sufficient to counterbalance the merit of the Grapes in Mr. Goodacre's exhibit. Taking these first, the following were the varieties shown:—Canon Hall, bunches of moderate size, berries large and fairly ripe; Gros Colman, neat bunches, fine berries, and well coloured; Muscat of Alexandria, large bunches in excellent condition; Black Hamburgh, berries not of great size, but admirably coloured, and the bunches of useful size; Foster's Seedling, good even bunches, berries a trifle small but fairly ripened; and Venn's Black Muscat, good bunches, bearing fine bloom. Pine Apples were represented by an unnamed fruit of moderate size, but well ripened, and a handsome example of Pernambuco. Three varieties of Peaches were shown—namely, Late Admirable, of good size and colour; Princess of Wales, large and of rich colour; and Bellegarde, equally good. Dishes of well-ripened Jargonelle Pears, Ischia Figs, Moorpark Apricots, McLaughlin's Gage Plum, fine; and Morello Cherries, excellent, were also noteworthy. Two Melons, one Miles' Victory of Bath, and the other unnamed, but both in fair condition, with Victoria Nectarines of moderate quality, completed this collection. Mr. George Sage, Ashridge Park Gardens, Great Berkhamstead, followed closely, the merit and diversity of his exhibits clearly entitling him to that position. The collection comprised good Black Alicante and Foster's Seedling Grapes; Scarlet Gem, Eastnor Castle, and The Squire Melons, the latter of great size; Elruge Nectarines, beautifully ripened; a magnificent bunch of ripe Bananas (*Musa Cavendishii*); a neat Smooth Cayenne Pine Apple; Morello Cherries, of good size; Goliath, White Magnum Bonum and Kirke's Plums, all good; Moorpark Apricots; handsome Royal George Peaches; ripe Brown Turkey Figs; a fine dish of Filberts; Kerry Pippin Apples, neat; White Dutch Currants, a dish of Bigarreau Cherries, and fruits of the edible Passion Flower (*Passiflora edulis*), which are very rarely seen at exhibitions. The

third prize was awarded to Mr. John Austin, Ashton Court Gardens, Bristol, who staged some well-grown fruit, but the collection was not sufficiently good all round to entitle it to a higher position. The most noticeable of the exhibits were Exquisite Peach, very fine, grandly coloured, and well meriting its name; Morello Cherries, large; Rivers' Plum, good; Ashton Hybrid Melon, finely netted; and Brown Turkey Figs, well ripened. In the smaller class for ten varieties, though prizes of £6, £4, and £2 were offered, only three competitors appeared, the chief position being secured by Lord Carington, Wycombe Abbey, (Mr. Miles), with Muscat of Alexandria and Black Hamburgh Grapes in fair condition, especially as regards the bloom; Golden Gem and Read's Scarlet flesh Melons, very well coloured; Morello Cherries, good; Pine-apple Nectarines, Barrington Peaches, fine; Charlotte Rothschild Pine Apple, of good size; and a fine dish of Kirke's Plum. Mrs. Lambert, Sandhill, Bletchingly (Mr. C. Goldsmith), obtained the second prize with fruits but little inferior to the first in the majority of the varieties staged. A bunch of Black Alicante Grapes was particularly fine, the size, colour, and bloom being admirable; Read's Scarlet-flesh Melon and Pine-apple Nectarines were also of more than ordinary merit. Third honours were awarded to the Earl of Ellesmere, Worsley, Manchester (Mr. W. P. Upjohn), for good examples of Brugnon Nectarines, richly coloured; and Raisin de Calabria, Venn's Black Muscat and Black Hamburgh Grapes, of fair size but not very well finished.

Grapes.—These were well represented in numbers, and several examples of exceedingly good quality were also staged. Seven classes were devoted to them, and over forty collections were entered in competition, the contest in some classes being very keen. In that for five varieties, one bunch of each, there were seven entries. W. Just, Esq., Eastham, Cheshire (Mr. McMaster), being first with magnificent Grapes that were greatly admired for their size and superb finish. The varieties were Buckland Sweetwater, grandly ripened, neat bunch, and beautiful colour; Madresfield Court, excellent colour; Muscat of Alexandria, large bunch and berries; Black Alicante, superbly coloured, bunch fine; and Mrs. Pince's Black Muscat, very handsome. The Baroness L. de Rothschild, Gunnersbury Park, Acton (Mr. J. Roberts), secured the second prize also with highly meritorious fruit, Madresfield Court, Foster's Seedling, and Muscat Hamburgh being very fine; the other varieties were Black Hamburgh and Muscat of Alexandria. Mr. Miles took the third position with neat bunches, but not so well finished as in the other two collections—Lady Downe's, Foster's Seedling, Black Prince, Trebbiano, and Black Hamburgh were the varieties. For three bunches of Black Hamburgh Grapes there were seven competitors. Messrs. Miles and J. Roberts were first and second respectively with fine bunches, well ripened and coloured; the two lots being very close in quality, but the berries in the former collection were slightly the larger. Mr. John Gadd, Thornden House Gardens, Brentwood, was third with creditable bunches of a fairly good colour. The class for three bunches of Muscat of Alexandria was a comparatively strong one, eleven competitors entering. The general quality was not so satisfactory as might have been desired, but very fair examples were staged in the three winning collections from E. C. Glover, Esq., Highfield House, Leek (Mr. C. Roberts); J. Atkinson, Esq., Gunnersbury House, Acton (Mr. J. Hudson); and H. J. Ashton, Esq., Bishopsgate House, Staines (Mr. P. Feest), who were first, second, and third respectively. For three bunches of any other white variety, among nine competitors, Mr. J. Roberts secured the chief prize with Foster's Seedling, fine even bunches, remarkably well ripened and of excellent colour, one bunch being particularly notable in that respect. Mr. G. Sage followed also with that variety, which though of good colour was not quite so even and neat. Mr. McMaster was third with Buckland Sweetwater, bunches and berries of good size. There were eight entries in the class for three bunches of any black variety of Grape except Black Hamburgh, and at least two collections were exceptionally fine—namely, the Madresfield Court from Mr. J. Roberts, and the Black Alicante from Mr. McMaster, for which first and second prizes were awarded in the order mentioned. These Grapes were nearly equal in merit, but the great size of the berries combined with the finish of the Madresfield Court secured the chief award to Mr. Roberts, but the bunches of Black Alicante were of such fine size and grand colour, with large berries, that it was scarcely possible to find a fault in them. D. P. Bell, Esq., Clive House, Alnwick, obtained the third prize for three neat well-coloured bunches of Alnwick Seedling. In the classes for the heaviest bunches of black and white Grapes the exhibits were unsatisfactory, and the first prize was withheld in both cases. There was no entry in the class for ornamental baskets of Grapes.

Pine Apples.—These were not very numerous, but several handsome fruits were staged. In the class for three fruits of the Queen variety the only exhibitor was Mr. J. Roberts, who well deserved the first prize which was awarded to him. One large, even, and beautiful fruit weighed 6 lbs.; and the others, also of excellent shape, were 5 lbs. 7 ozs. and 5 lbs. 1 oz. respectively. For one Smooth Cayenne Pine Apple chief honours were obtained by Earl Fortescue, Castle Hill (Mr. D. Wilson), with a fruit of good size and very symmetrical, weighing 6 lbs. 13 ozs.; C. R. M. Talbot, Esq., Margam Park, Glamorganshire (Mr. J. Muir), being second with good and finely-formed fruit. In the class for one fruit of any other variety Mr. D. Wilson carried off the chief prize with a handsome example of Charlotte Rothschild, good shape and large pips; Mr. Miles followed with a

fine but unnamed fruit. Mr. D. Wilson obtained an extra prize for six Smooth Cayenne Pine Apples of excellent quality.

Peaches and Nectarines.—These were well represented in the two classes devoted to them, there being nine exhibitors of the former and eight of the latter. For a dish of twelve Peaches R. Leigh, Esq., Barham Court, Maidstone (Mr. C. Haycock), was placed first with handsome, large, finely-coloured fruits of *Violette Hâtive*, which were very creditable to the exhibitor. Captain Jackson, Meopham, Kent (Mr. R. Phillips), was awarded the second prize for *Reine des Belges*, of fine colour and good size; W. R. Winch, Esq., North Mimms Park, Hatfield (Mr. J. Seymour), being third with large examples of *Salwey*. In the corresponding class for Nectarines C. H. Firth, Esq., Riverdale, Sheffield (Mr. D. Abbott), secured the chief award, a dish of *Victoria*, very large and well coloured. R. C. Naylor, Esq., Hooton Hall, Chester (Mr. Hanagan), followed with neat highly coloured fruits of the variety *Pine Apple*; Mr. J. Gadd taking third for *Elruge* of fair quality. Apricots were only represented by three collections, first, second, and third prizes being secured by Lord Ebury, Moor Park (Mr. Mundell), Mr. Goodacre, and Mr. G. Sage.

Melons.—Two classes were devoted to these—namely, one to green-fleshed and the other to scarlet-fleshed varieties; about forty fruits were exhibited, nearly equally divided between the two classes, and presented a formidable task to the Judges. The prizes for a single fruit of a green-fleshed variety were obtained by Mr. J. Gadd with a well-ripened fruit resembling *Bromham Hall*, with a fair example of which variety Mr. P. Feest secured the second prize. Mr. H. A. Mann, St. Vincent's Lodge, Grantham, was third with an unnamed fruit of average merit. The general quality of the unsuccessful exhibits in the class was not of great merit. Mr. J. Muir was first with a scarlet-fleshed Melon, very good in form, well ripened, and finely netted; Mr. C. Goldsmith was second with *Scarlet Gem* of good quality; and Mr. Miles was third with *Read's Scarlet-fleshed*, fairly well ripened. Figs were few and not first-rate, Mr. G. Sage was accorded the second prize for a dish of *Brown Turkey*. Plums were similarly deficient, Mr. Miles taking the first prize for fair examples of *Magnum Bonum*.

Pears.—Three classes were provided for Pears, and although the entries were not very numerous the quality was fairly good for the season. In the class for a collection of Pears, to include six fruits of each variety, C. Hardwick, Esq., Hollenden, Tunbridge (Mr. G. Goldsmith), was first with forty dishes of as many distinct varieties, some of the fruits being of good size. The following were the most noteworthy:—Williams' *Bon Chrétien*, *Maréchal de Cour*, *Doyenné du Comice*, *Marie Louise*, *Chaumontel*, *Beurré d'Amanlis panachée*, *Glou Morceau*, *Beurré d'Anjou*, *Souvenir du Congrès*, *Beurré Clairgeau*, *Doyenné Boussoch*, *Bonne d'Ezée*, *Beurré Diel*, *Catillac*, and *Gansel's Bergamot*. Mr. G. de Faye, Jersey, was second with twenty dishes of fine Pears, including the following in excellent condition:—*Doyenné Boussoch*, *Beurré Diel*, *Beurré d'Été*, *Duchesse d'Angoulême*, *Louise Bonne of Jersey*, *Chaumontel*, *Marie Louise*, *Beurré Bachelier*, *Beurré d'Amanlis*, and *Glou Morceau*. Mr. P. F. Le Sueur, Jersey, was a good third with sixteen dishes of well-selected varieties. For a dozen *Jargonelle* Pears there were six entries, none, except the two winning collections, being of remarkable merit. Mr. G. Goldsmith was first with fruits of medium size, good shape, and fairly ripe; J. Fisher, Esq., Ebor House, Stamford Hill, N. (Mr. G. Hood), being second with fruits of good size, but not so ripe. Mr. G. Goldsmith was also first in the class for twelve fruits of any variety except *Jargonelle*, staging a dish of Williams' *Bon Chrétien* of moderate quality, Mr. G. de Faye following with the same variety, green, but large.

Apples.—There was a fine display of Apples both in the classes and not for competition, a very large number of varieties being represented by characteristic fruits. In the class for six varieties of baking Apples, six fruits of each, there were eight entries. Mr. C. Haycock was an admirable first with beautiful specimens of *Lord Derby*, *Washington*, *New Hawthornden*, *Lord Suffield*, and *Stone's Apple*. Mr. G. de Faye followed closely, *Emperor Alexander*, *Alfriston*, and *Beauty of Kent* being the best. Mr. Miles was third. There were fourteen entries in the class for twelve baking Apples of one variety, Mr. P. Le Sueur taking the first prize with very fine examples of *Incomparable*, Mr. J. Austin being second with *Lord Suffield* of fair quality. In the class for a collection of dessert Apples, six varieties, six fruits of each, Mr. Haycock was awarded first honours for handsome specimens of *Devonshire Quarrenden*, *Golden Pippin*, *Jefferson*, *Summer Golden Pippin*, and *Mother Apple*. F. Whitbourn, Esq., Loxford Hall, Ilford (Mr. J. Douglas), was placed second with a creditable collection, in which *Early Harvest*, *Kerry Pippin*, *Worcester Pearmain*, and *Gravenstein* were noteworthy. Mr. G. de Faye was third, three other exhibitors staging fair examples, but not sufficiently good to obtain them a place in the prize list. Messrs. C. Roberts and Miles were first and second with *Devonshire Quarrenden* in the class for dessert Apples fit for table.

Small fruits were represented by few collections. For a dish of Gooseberries Messrs. Sage and Goodacre were first and second respectively with *Warrington* in good condition. Mr. G. Goldsmith had the best dish of *Red Currants*, the variety being *Red Dutch*, while Mr. G. de Faye was the only exhibitor of *White Currants*. Messrs. Lane & Son, Great Berkhamstead, Herts, were the only exhibitors of four Vines in pots, and obtained the first prize for handsome specimens of *Black Hamburgh* and *Foster's Seedling* in vigorous health, and remarkably well fruited.

Tomatoes.—In the class for twenty-four Tomatoes of one or more varieties Mr. S. Castle, The Vineyard, King's Lynn, Norfolk, was awarded chief honours for a collection comprising twelve fruits of *Trophy* and twelve of *Improved Red*, which together weighed 14 lbs. The fruits were of good shape and fine colour. The same exhibitor staged twenty-four fruits of *Stamfordian* which weighed 21 lbs., but they were very coarse in form. Mr. Robert Farrance, Chadwell Heath, Essex, was second with fine even specimens of *Trophy*. Capt. Wingfield, Orsett Hall, Ilford, Essex (Mr. W. Iggulden), also exhibited a collection of very even and excellent fruits. There were six other exhibitors, thus constituting a very fair display.

Miscellaneous Exhibits.—These were numerous and attractive, the most important being the superb collections of Apples from Messrs. Veitch & Sons of Chelsea and Messrs. Paul & Son of Cheshunt, which were highly commended by the Judges. Messrs. Veitch exhibited more than a hundred varieties, well representing the best in commerce; the condition of the fruits as regards size and form was also excellent. Messrs. Paul had about fifty carefully selected varieties, several being exceedingly fine. The latter firm also contributed a number of cut Roses. Mr. H. Cannell, Swanley, Kent, sent cut flowers of *Tigridias*, *Asters*, and *Dahlias*, all in their customary fresh healthy condition. Mr. J. Gilkes, Wickham Nursery, Newbury, sent a collection of quilled *Asters*, very fine; Messrs. J. Cheal & Son, Crawley, Sussex, samples of Apples, Cucumbers, and Melons; and Mr. Boller a group of succulents. J. Southgate, Esq., Selborne, Leigham Court Road, Streatham (Mr. C. J. Salter), exhibited fruits of a seedling Cucumber named *Selborne Rival*, a cross between *Marquis of Lorne* and *Tender and True*. The variety was said to be very prolific, and was commended.

Nothing could exceed the courtesy of the officials extended to all who were in any way identified with this excellent Exhibition.

COOL HOUSE ORCHIDS.

A FEW years ago cool house Orchids were but little understood, and the prices were so high that they could only be obtained by few. They are now, however, within the reach of many, and of such easy cultivation that they could be accommodated in gardens of small extent where there is a greenhouse. They will do well in cold frames from the end of April until October where they could have the exact treatment they require—that is, plenty of water at the root, and abundance of air with moderate shade. I think it is not sufficiently known that many Orchids can be grown in a cool temperature, or they would be more generally met with. They are great favourites with most ladies and gentlemen, and have more attractions than most flowers, either in the forms or delicacy of colour in the flower or the sweet perfume many possess. To prove that some species will endure very low temperatures, I may mention that the temperature of our cool house frequently falls as low as 35° to 40° during winter, and on one occasion to 33°, and the plants were not injured in the least. Not that I recommend a temperature below 40°, but this is abundant for them, and far more likely to induce a vigorous growth and abundance of bloom than the usual temperature of many cool Orchid houses. Take for instance a cool species, and winter it in a temperature of from 60° to 70°, and then give it greenhouse treatment the following summer—it will scarcely move in growth. Plants so treated will rest for months in a temperature of from 60° to 80°, and commence growing in autumn in a temperature from 40° to 50°. This clearly proves that to obtain a vigorous summer growth the plants must be wintered in a proportionately low temperature.

It must be remembered that this class of Orchidaceous plants cannot endure strong sunshine while growing, yet the shading material employed should be moveable, so as to give the plants abundance of light. This I consider is a very important point in cool house Orchid culture. Air should circulate through the house night and day when the external atmosphere will allow of it; they cannot endure a close confined atmosphere, nor take the same amount of water as if air is admitted freely. Watering should be liberally done on fine mornings before the sun has much power. The plants are watered overhead with a coarse-rose can, so that the bed of gravel the plants stand upon is thoroughly saturated also; this is repeated in the afternoon in very fine weather. During the season of growth too much water cannot be given, nor will the young growths damp with these copious waterings if ventilation is in proportion. Damping of the young growths is frequently caused by a close stagnant atmosphere. Some varieties are subject to one kind of insect more than another. For instance, *Odontoglossum Phalaenopsis* is subject to red spider; *O. Alexandræ*, *O. Pescatorei*, and many others of a strong constitution to thrips and green or yellow fly; while *O. grande* and *O. Insleyi* are affected with scale. The best preventive for all is abundance of water and air.

In potting, the pots should be clean and two-thirds filled with clean crocks, and the material employed should be well elevated above the rim of the pot. Good brown fibrous peat should be

used in a rough state, and mixed with equal quantities of sphagnum moss. The surface should be entirely covered with moss, the green ends being preserved for this purpose; it will soon grow rapidly if watered as directed. The best time to repot these Orchids is when the young roots have commenced growing from the base of the young growths, they soon establish themselves in the fresh compost. I am in favour of small shifts, for the plants do better when the roots reach the sides of the pots, and take water more freely than when large pots in proportion to the plants are used. There is but little fear of water stagnating about the roots of the plants if the drainage is perfect. The compost frequently becomes sour when inferior peat is used, and it is better to dispense with peat altogether if bad, for the plants succeed much better in crocks with a portion of sphagnum on the surface. Often good results are obtained by employing crocks, especially with plants that have become unhealthy and lost many roots. After considerable experience with imported Orchids, I find they always establish themselves better in crocks than in peat. Some kinds succeed best when suspended in baskets from the roof, especially such dwarf growers as *Odontoglossum Cervantesii*, *O. Rossii*, *O. Ehrenbergii*, *Epidendrum vitellinum majus*, and others of a similar habit. Other dwarf species do well on blocks with sphagnum, but I avoid blocks as much as possible, because they require more attention in watering during summer.

It is sometimes difficult to bring imported Orchids at first to this system of cultivation, because the great heat of the voyage often stimulates an untimely growth, which cannot be severely checked without injuring the plant. It must, however, be gradually adopted, and not till it is done shall we see some of the short, stiff, leathery growth, and rich purple-tinted stems we find in the imported specimens. We appear to aim at size, but it is not the standard of excellence in Orchids.

The following is a list of the cool house Orchids cultivated at Lee Hall:—

<i>Angloa Clowesii</i>	<i>Oneidium crispum</i>
<i>Ruckerii</i>	<i>crispum grandiflorum</i>
<i>Ada aurantiaca</i>	<i>prætextum</i>
<i>Cœlogyne cristata</i>	<i>cueullatum</i>
<i>corymbosa</i>	<i>cuenllatum major</i>
<i>barbata</i>	<i>serratum</i>
<i>corrugata</i>	<i>nubigenum</i>
<i>speciosa</i>	<i>flexuosum</i>
<i>Epidendrum vitellinum</i>	<i>auriferum</i>
<i>vitellinum majus</i>	<i>spilopterum</i>
<i>syriugothyrus</i>	<i>Rogersii</i>
<i>Odontoglossum Alexandræ</i>	<i>varicosum</i>
<i>blaudum</i>	<i>pelecanum</i>
<i>cirrhosum</i>	<i>cheiroporum</i>
<i>Cervantesii</i>	<i>tigrium</i>
<i>Cervantesii decorum</i>	<i>pubes</i>
<i>coronarium</i>	<i>ornithorhynchum</i>
<i>cordatum</i>	<i>Lælia majalis</i>
<i>Dawsonianum</i>	<i>autumnalis</i>
<i>Ehrenbergi</i>	<i>albida</i>
<i>Egertonii</i>	<i>auceps</i>
<i>grande</i>	<i>Leptotes bicolor</i>
<i>gloriosum</i>	<i>Lycaste Skinneri</i>
<i>Hallii</i>	<i>cruenta</i>
<i>Insleayi</i>	<i>Mesospinidium sanguineum</i>
<i>Insleayi leopardinum</i>	<i>Sophranites cernua</i>
<i>Lindeni</i>	<i>grandiflora</i>
<i>Lindleyanum</i>	<i>Masdevallia amabilis</i>
<i>maculatum superbum</i>	<i>ignea</i>
<i>madrense</i>	<i>ignea splendens</i>
<i>maxillare</i>	<i>ignea violacea</i>
<i>nebulosum</i>	<i>eoccinea</i>
<i>nebulosum eandidulum</i>	<i>Lindeni</i>
<i>pardinum</i>	<i>Veitchii</i>
<i>pulehellum</i>	<i>Davisii</i>
<i>roscum</i>	<i>sanguinea</i>
<i>stellatum</i>	<i>sanguinea superba</i>
<i>Wallisii</i>	<i>Harryana</i>
<i>sceptrum</i>	<i>Harryana splendens</i>
<i>odoratum</i>	<i>trochilus</i>
<i>Rossii major</i>	<i>caudata</i>
<i>luteo-purpuratum</i>	<i>chimæra</i>
<i>nævium major</i>	<i>melanopus</i>
<i>Andersonianum</i>	<i>Restrepia antennifera</i>
<i>triumphans</i>	<i>Disa grandiflora</i>
<i>Pescatorei</i>	<i>Cypripedium insigne</i>
<i>membranaceum</i>	<i>insigne Maulei</i>
<i>Oneidium macranthum</i>	<i>Renanthra eoccinea</i>
<i>macranthum hastiferum</i>	

—JOHN GLOVER, *Lee Hall*.

GREENING SEED POTATOES.—Greening seed Potatoes is an old practice, but a very good one. It consists of placing the tubers in the sun for a time after they have been taken from the ground until they are quite green. They become green equally well in a shady place, and this, I think, is the best, as I have lately seen some tubers which were so much exposed to the sun that they were quite shrivelled. Potatoes keep better during the winter in a green state, and they are much hardier for

seed than those that have not been so prepared.—A KITCHEN GARDENER.

ATHERSTONE HORTICULTURAL SOCIETY.

THIS Society held its first Exhibition on the 1st inst. in Merevale Park, the seat of W. S. Dugdale, Esq., the President of the Society, who kindly placed his grand park, which is second to none in the midland counties, at the disposal of the Committee. The Committee and their Hon. Secretary, Mr. Alfred Sale, worked together with a will, and the result was that a fine collection of plants, flowers, fruit, and vegetables was brought together. There were over a thousand entries, and the Judges had a hard day's work, especially as the competition in some classes was remarkably keen.

In the first class for the best collection of plants arranged for effect there were six entries, the space allotted to each competitor being 18 feet by 12 feet, arranged crescent-shaped against the side of the tent. Here the Judges had a difficult task to decide the first prize, and ultimately the collections shown by W. S. Dugdale, Esq., of Merevale Hall (Mr. W. Brown, gardener), and Mr. J. Parker of the Victoria Nurseries, Rugby, were declared equal, and the first and second prizes were divided between them. The third prize was awarded to Mr. E. Holmes, nurseryman, Lichfield, and the fine collections of Mr. A. Waters of Coventry and Messrs. R. & F. Allum of Tamworth were highly commended. The collection by Mr. G. J. Sale was also commended, but the deficiency of colour precluded it from taking a prize, although it included several high-class specimens. In the classes for plants in pots there were some excellent exhibits, and the competition was again very keen, Mr. A. Waters of Coventry carrying off no less than seven first and four second prizes. In the classes for cut flowers Mr. Kimberley of Stoke Nurseries, Coventry, was eminently successful, and succeeded in taking six first prizes, four seconds, and one third. The classes for fruit were also well filled, Mr. Hanson Sale carrying off both first prizes for black and white Grapes; Mr. Forsey, gardener to Sir George Chetwynd, Bart., taking both seconds in the same classes.

The roots and vegetables were also far above the average. The cottagers' classes were on the whole well filled, and the exhibits wonderfully good. There was also an exhibition of butter and eggs, which was one of the great features of the Show, Mr. Choyce of Pinwall taking the first prize for butter, and the Marchioness of Hastings the first prize for eggs.

It is seldom that a Society meets with such a marked success on a first attempt, and the Committee may be congratulated upon having brought together such well-known nurserymen and florists as Messrs. Parker and Bryant of Rugby, Messrs. Waters and Kimberley of Coventry, Mr. Holmes of Lichfield, and Messrs. Allum of Tamworth. —(Communicated.)

CARTERS' LEVIATHAN BEAN.

I SEND you specimens of this fine long-podded Broad Bean grown by me. One peculiar feature in this Bean, which I have not seen remarked upon by anyone is, that when the crop was fit for gathering, two, three, and in some instances four growths issued from the bottom of the stems, and are now producing a second crop, from which I am gathering. The ripe pod I send you is from the first crop, and the green one from the second. I consider this Bean the heaviest cropper I have ever grown, and the flavour equal to any other variety. I have had numerous pods this season between 14 and 16 inches in length, containing seven beans in a pod.—THOMAS JELFS, *Hungerford*.

[The dried pod is 13 inches long, and contains eight beans quite hard and ready for sowing. The green pod is nearly 10 inches long, and contains seven very large beans in good condition for cooking.—EDS.]

RED SPIDER IN VINERIES.

"MID-SURREY'S" letter on this subject in your last issue was to my mind a slight misnomer, for in the case adduced the insects do not appear to be in the vinery at all, but outside it. I will refer to an instance of red spider on the Vines in a house, and how in a very simple manner I got rid of thousands of insects. Like your correspondent I reside in a "red spider district," for I am in the same county. Kidney Beans, Vines on walls, and even on some forest trees, are being devoured with this insect, that infests them by millions.

In the vinery in question the young laterals with small leaves from 1 to 3 inches in diameter were rather seriously attacked, but the older leaves on close examination did not appear to be touched. I therefore carefully cut out those infested laterals, which were not numerous, and did not let them fall to the ground, but placed them in a pail of water as they were cut and carried them out of the house. I then, towards evening, gave the Vines a heavy washing, directing the syringe carefully between the bunches, and applying the water with great force. The house was thoroughly drenched, and although the water fell on the bunches it did not

wash the berries, but formed globules as if on Cabbage leaves. An hour or two afterwards the Vines were shaken and the water drops dislodged from the foliage and bunches. The next day no one could tell from the appearance of the berries, which were half coloured, that the Vines had been syringed at all, for scarcely a particle of bloom was moved. The result of the two-hours work is, that the Vines look much better for the heavy shower to which they were subjected, while not a red spider can be found in the house. A week ago there were certainly hundreds, and probably thousands, but by the prompt removal of the laterals, and the vigorous yet very careful syringing, I have now a clean house.

I have little fear now that the thick leathery foliage will be attacked by the pest if I prevent, as I intend doing, the formation of fresh laterals with their thin delicate foliage to invite the insects into the house. With from three to five good leaves beyond the bunches, according as there was space for them to expand, lateral growths at this season can very well be dispensed with, and better still can red spider, which such growth certainly encourages during bright and hot weather.—W. J., *West Surrey*.

DERBYSHIRE HORTICULTURAL SOCIETY.

SEPT. 1ST AND 2ND.

THE annual Exhibition of the above Society was held in conjunction with the Agricultural Exhibition at Derby. The show of plants was a very good one, and quite equal to former years; but there was a falling-off in the number of exhibitors of fruit.

Plants.—In the nurserymen's class for twelve plants Mr. Cypher of Cheltenham was first, showing six fine-foliage plants and six in bloom, comprising well-grown handsome specimens. Messrs. E. Cole and Sons of Manchester were a very good second, with their usual good plants. Messrs. Small & Son of Ilkeston were third. In the gentlemen's gardeners' corresponding class T. H. Oakes, Esq., Riddings House (Mr. Ward), was easily first with a good collection, the following being noteworthy:—*Kentia Fosteriana*, *Latania borbonica*, *Dicksonia antarctica*; *Croton variegatus*, an immense bush, and well coloured; *C. Weismanii*, *Cocos Weddelliana*, *Dasyliroium glaucum*, *Ixora Williamsii*, very good; *I. Fraseri*; *Allamanda Hendersonii*, and *Dipladenia amabilis*. H. Evans, Esq., M.P., Allestree Hall (Mr. Milford), was second, his best plants being *Areca lutescens*, *Croton pictus*, *C. longifolius*, small but good; *Maranta Veitchii*, and *Alsophila australis*. His flowering plants were rather weak, the best being *Allamanda nobilis*. Mr. Gilbert was a very close third. *Selaginellas* were remarkably fine. G. Meynell, Esq., Meynell Langley (Mr. Robinson), was first with *S. cæsia arborea*, *S. Wildevonii*, *S. Mertensii*, and *S. apoda*. Mr. Milford was a good second with *S. cæsia arborea*, *S. stolonifera*, and others. *Pelargoniums* were not first-rate, Mr. Ward being first for tricolor varieties, and Mr. Robinson first for zonal varieties. Mr. Milford staged a very neat and effective basket of plants, for which he was awarded the chief prize.

Cut flowers were very well shown, especially Dahlias. Mr. Edwards, nurseryman, of Nuthall, Nottingham, being first with collections of twelve and six. The same exhibitor staged an excellent stand of four dozen not for competition, as well as a stand of Pompons. Messrs. Perkins & Sons of Coventry were first with twelve Roses, Mr. Henson of Derby being first for six Asters. Marigolds, Gladioli, &c., were also well shown, Mr. Henson being the principal prizetaker. Mr. Cypher had the best bouquet, followed by Mr. Henson. There was a spirited competition for table decorations and bouquets, to be arranged by ladies. In the former there were seven competitors, Mrs. Bolas being first with a very neat stand of flowers, Mrs. Ward of Riddings second, and Mrs. J. Henson third. In bouquets there were fifteen exhibitors for the six prizes offered, Miss Butler of Marlpool, near Derby, being an easy first, Mrs. Butler second, Mrs. Ward third, Miss Cypher fourth, Mrs. J. and Mrs. Isaac Henson fifth and sixth.

Fruit.—There was only one exhibitor in collection of ten dishes of fruit—Mr. Ward, who had very good Madresfield Court and Muscat of Alexandria Grapes, Peaches, Nectarines, Melons, Figs, Plums, &c. Mr. Ward was first for black Grapes with fair examples of Black Hamburgh. The Hon. E. Coke, Longford Hall (Mr. Edwards), was a very close second, and Mr. Robinson third. Mr. Ward was a long way ahead with white Grapes with Muscat of Alexandria, good in berry, bunch, and colour; Mr. Edwards was second, and Mr. Robinson third. Mr. Ward was the only exhibitor of a Pine Apple: he was also first with two Melons, Luscious and Melting, and for Peaches. Mr. Gilbert was first for Nectarines, and Mr. Milford for Cucumbers, having an excellent brace.

Vegetables were very good, there being five collections staged. Mr. Ward; R. C. Curzon, Esq., Lockington Hall (Mr. Woolton); and Mr. Wright, Manor House, Borrowash, were the prizetakers. The last-named exhibitor staged a bunch of Grapes not for competition that weighed about 7 lbs., the berries being a fair size and good colour for the size of the bunch. It was not named, but it resembled Gros Guillaume.—G.

NICOTINE SOAP v. EARWIGS.—I observe by your reply to a correspondent that you have no data as to the efficacy of nicotine

soap in destroying earwigs. I found a colony of these pests, and subjected them to a syringing with a solution of about 8 ozs. to a gallon of water, and they were destroyed instantly. I have no doubt of its proving equally efficacious with ants, but I cannot find any to try it upon.—G. ABBEY.

TOMATO, THE CONQUEROR.

YOUR esteemed correspondent, Mr. W. Iggulden, describes The Conqueror Tomato as being corrugated (see page 180). It is no more corrugated than an egg, and that is more than can be said of a single Tomato in the list which he gives. He has not grown it, or he would say that it was the best Tomato. I can speak confidently about it, for I had our seed direct from America from the raiser. Why does Mr. Iggulden call The Conqueror "commoner" than The Trophy? He ought to know that The Trophy was "common" years before The Conqueror was raised.—SINGLE-HANDED.

SCHIZANTHUSES IN POTS.

SOME weeks ago Mr. Pettigrew directed attention to the desirability of growing *Schizanthuses* in pots for spring and early summer decoration in the conservatory. The grand plants he there refers to I saw at Cheetham Hill about twenty-eight years ago,

Fig. 49.—*Schizanthus papilionaceus*.

and I have never seen any to equal them since. The seed was sown in July, and the plants—grand specimens, 3 feet high and through, bearing thousands of flowers—were flowered in 11-inch pots.

I desire now to say that much smaller plants than those are most valuable for decorative purposes—plants from 1 foot to 18 inches high, and the same in diameter, and covered with hundreds of "butterfly-like" flowers. Such plants may be grown in 5 and 6-inch pots from seed sown at the present time. It should be sown very thinly in a compost of two-thirds turfy loam, the remainder consisting of decayed manure and wood ashes in equal parts. The moment the seedlings can be handled they must be thinned out, leaving five or six in each pot, and these must be grown in a light position and not be topped. If the plants are intended to be flowered in 5-inch pots the seed may be sown in those pots, which however should not be filled quite full of soil, but a little space should be left for a top-dressing of manure; if required to flower in 6-inch pots sow in pots 4 inches in diameter, which must be washed clean, especially inside, and dried before using, or the roots will be injured when the plants are placed in their flowering pots. A frame is suitable for the young plants until cold weather occurs, they must then be placed on a shelf in a light greenhouse, the temperature of which should not fall below 40°. They require careful watering through the winter, but when growing rapidly in the spring the supplies must be copious, and as the flowering period approaches the pots should be placed in

saucers, and clear soot water may be given with advantage twice or thrice a week.

S. retusus is very rich in colour, but lacks the elegance and grace of *S. pinnatus* and *S. papilionaceus*. The last-named is very charming, and once produced in good condition will be regarded as indispensable for decorative purposes. If not required for flowering under glass these plants are highly worthy of preparation in the manner indicated for planting in the flower garden in March or April.—J. W. B.

MORE ABOUT POTATOES.

MR. R. W. BEACHEY in his excellent article in the *Journal* of September 2nd alludes to some remarks of mine on the Potato (*vide Journal* August 5th), and pronounces them "Fallacy No. 1." Now I think the brevity of my remarks, out of consideration for your space, has been the cause of this judgment, as I feel convinced from the latter half of Mr. Beachey's article that our principles of Potato culture are identical, although differing somewhat in detail. He is quite correct in his description of the result of planting the largest Potatoes whole, also that generally the largest in a crop are the most diseased. It is, I believe, generally allowed that the attacks of disease are modified somewhat by the stage of maturity of the tubers, and I think this explains how the largest are often more diseased than the others. Planting large Potatoes whole is, I am convinced, a mistake, as you get only about one-fourth of what the same Potato would have produced if cut into pieces of one or two eyes each, and the crop in the latter case would be far more even in size.

My authority for cutting when I commenced were the experiments of the late Professor Lindley at the Gardens of the Royal Horticultural Society. I believe Mr. Beachey to be quite correct in his remarks on saving seed yourself and not buying in the spring. My way is to select seed when the crop is dug, spread the tubers in a single layer on the floor of an attic exposed to the light from a window in the roof; there they remain till taken for planting, only having been covered during severe frost with a piece of matting. The result is they become green in colour, have short stout shoots and are not shrivelled, which I consider the essentials in a seed Potato.

When planting each tuber is cut into pieces of two eyes (to make sure of a plant if one shoot is accidentally broken off), commencing cutting at the stem end; the sets are then dusted in dry lime and dug into the previously manured bed about 9 inches to a foot apart in the row, and the rows about 18 inches from the next. The Potatoes are not earthed at all; if the soil is light the weeds are hand-pulled, if heavy it is worked once or twice with a pronged hoe.

I quite agree with Mr. Beachey that Champions and Magnum Bonums are not the varieties wanted, and prefer those of something the style of Snowflake, which ripen moderately early, keep well into the spring, and the stems of which are not too luxuriant.

There is no doubt we are at the mercy of the weather, yet Mr. Beachey shows that in spite of this he has for fourteen years saved seed of Gloucestershire Kidneys, which are as good now as they were at first. This is what I call retaining the constitutional vigour of a Potato thoroughly well.

In conclusion, the only point that I see at present on which we are not agreed is, Which are the tubers to reserve for seed? Maturity of growth must come first, after this Mr. Beachey thinks the medium in size, and at present I think the largest have the most vigorous shoots and produce the finest crops.

All this does not banish the disease, but I believe it does the next best thing—namely, mitigates its severity.—W. B. W.

GOOD DAHLIAS.

THESE popular flowers are now in their best condition, and a good opportunity is afforded for making a selection of the most distinct and handsome varieties. Several catalogues are issued by the chief growers of Dahlias, with accurate descriptions of the varieties in commerce; but intending buyers who have not the opportunity of personally inspecting the collections are confused by the great number enumerated, and are almost as much at a loss as if the descriptions were too meagre. It is for such that the following notes are intended; and as many who only possess gardens of limited extent have to content themselves with a correspondingly limited number of plants, a selection of about a dozen really good and generally useful varieties in each section may be of service.

Show Varieties.—These are so numerous and excellent, and so many new and meritorious varieties are being annually sent out, that selection is by no means an easy task where the collection is

limited to a few. However, the following will be found of fine quality and entitled to rank among the best, though they are equalled by many and possibly surpassed by some that have not come under my notice in the best condition. The new varieties appended to the principal list have been recently exhibited at Kensington and honoured with certificates—a sufficient indication of their merit, for a new Dahlia must possess some excellent qualities to obtain such a distinction now. A very handsome symmetrical flower is John Standish (Turner), of a rich reddish hue, attaining great size, and telling well in collections at exhibitions. Canary (Fellowes) is of fine form, good depth, very regular in outline, with a full centre, and of a clear bright yellow colour. Chris. Ridley (Turner) is a beautiful variety, with flowers of good substance, clean, neat in outline, deep, and of an extremely rich crimson tint, scarcely rivalled in hue when at its best. John Bennett (Rawlings), very distinct and effective, of neat form, the florets being tinged with yellow and tipped with scarlet, the contrast of the shades having a peculiar appearance. Lady Gladys Herbert (Keynes), like the last this is remarkable for the contrast of colours in the flowers, the body of the florets being white and the margin rich crimson; the flowers are usually of good size and symmetrical. Earl Radnor (Keynes), a handsome flower of considerable size, good form and substance, the colour being a warm purplish plum tint. John Greenaway (Fellowes), one of the finest crimson selfs, excellent in symmetry, size, and substance. Ovid (Turner), an exceptionally beautiful variety with large well-built flowers of great depth, good centre, and altogether a nearly perfect flower. The colour, too, is an additional attraction, the shade being very distinct—a deep clear puce. Samuel Plimsoll (Turner), a very attractive purple self, flower of good form. Toison d'Or (Turner), a charming bright yellow or golden-coloured variety, admirable in all respects. Sarah McMullen (Rawlings), a pretty variety with mauve-coloured symmetrical flowers. Picotee (Keynes), is a bright variety, the florets of which are of a golden yellow tinge margined with crimson. Among the glowing colours the following are especially noteworthy:—Victory, crimson; Vivid, scarlet; Crimson King, fine tint; Dauntless, orange; and John Laing, bright crimson, all of Keynes' raising; while among whites, Julia Wyatt (Keynes), Mrs. Hartopp Nash (Turner), Mrs. Henshaw (Turner), and Purity (Fellowes), are noteworthy. Among the new varieties the following are especially deserving of notice:—Cyprus, a fine flower, excellent in form, and of a pale orange tint, the edges of the florets being faintly tinged with red. Mr. Spofforth, a handsome rich crimson flower of good substance; Helen Macgregor, white, tipped with purple, deep and full in form; Revival, a grand variety, with flowers of moderate size, great depth, symmetrical form, and rich scarlet colour; and Goldfinder, a clear bright yellow variety, of excellent form and substance. All these have been raised by Mr. Fellowes, and the two last mentioned were exhibited by Mr. C. Turner at a recent meeting of the Royal Horticultural Society, when first-class certificates were awarded for them, honours that were also accorded to the following varieties from Messrs. Keynes:—Lady Wimborne, a beautiful variety with full neat flowers of a pale rose tint; James Vick, also excellent in form, rich purple in colour; and Mrs. Compton, fine purplish maroon colour, rather more globular than the preceding.

Fancy Varieties.—There is also a great number of these, many presenting some peculiar combinations of colours that are more striking than beautiful, but there are others of considerable beauty, the tints of the stripes or margins harmonising with the body colour very pleasingly. The forms of some new varieties are very good, but generally the fancy varieties would not come up to the standard of the show section in that respect. The undermentioned are all worth growing, and will bear comparison with any others in commerce:—Henry Glasscock, buff-coloured ground striped with crimson, rather variable; Monsieur Chauvière, lilac, spotted and streaked with rich crimson; and Grand Sultan, yellowish buff, striped with bright red, all of which are Keynes' varieties. Mrs. Saunders, a beautiful variety, yellow ground tipped with white, excellent form; and Peacock, deep purplish maroon, the florets edged with white, very distinct; both of Turner's raising. Singularity (Rawlings), yellowish ground colour, the florets tipped and edged with red and white, very aptly named; and Prospero (Goodwin), a fine flower, maroon colour edged with white. In addition to those noted above, Messrs. Keynes' Parrot, Maid of Athens, and Lucy Fawcett; Mr. Fellowes' Oracle; Mr. Turner's Pauline and Mrs. Standish; and Messrs. Rawlings' James Carter, are all good varieties.

Bouquet Varieties.—The improvements that have been effected in this section of Dahlias during recent years is remarkable. Not only have we a most satisfactory symmetry of form combined with diminutive size, but the colours are very rich and varied.

The majority of the varieties are extremely floriferous, and thus yield a very important supply of neat flowers of considerable usefulness for all purposes of decoration, particularly at a time when the general supply of other flowers begins to diminish. Mr. Turner has contributed to the improvement of this section, and Mr. Cannell has also worked successfully in the same direction, but some of the best and most distinct varieties I have yet seen are now flowering in the Royal Horticultural Society's Gardens at Chiswick, where a large number of continental forms are being grown. These comprise several of exquisite regularity and bright colours, the florets in some varieties having the margins recurved so as to impart a quilled appearance to the flowers. Perhaps one of the best is that which bears the name of the genial Superintendent at Chiswick, but the majority are dignified by names that almost defy English utterance. Of the varieties in commerce those appended are meritorious:—Louis Rodani, lilac; North Light, rich scarlet; John Sandy, orange shaded with yellow; Crimson Beauty, rich crimson maroon; Amelia Barbier, pale rosy pink, darker margin; Dr. Schwebes, fine scarlet; Fireball, bright red; German Favourite, crimson; Prince of Liliputians, maroon; White Aster, a good white; and Lady Blanche, undoubtedly the finest white variety, of admirable form and pure in colour. Of new varieties Dora, pale primrose; Hebe, rose tipped; Toby, dark scarlet; and Fair Helen, white tinted with lilac, are the best.

Bedding Varieties.—A list of Dahlias would not be complete without including some of those free-growing forms, which, although very bright and effective in beds, do not possess the type of flowers that florists regard with especial favour. Good habit and floriferousness combined with rich glowing and distinct colours are the principal requisites in this section, and a very fine display may be produced by the judicious planting of varieties possessing those qualities. The following will be found generally useful:—Flora Macdonald, primrose; Mont Blanc, white; Prince Arthur, crimson; Royal Purple, Cloth of Gold, Drap d'Or, Rising Sun, rich scarlet; The Pet, maroon, white tip; Marguerite Bruant, good white; Faust, fine deep maroon; Sir James Watts, scarlet; and Dark Model, fine crimson. Those enumerated in the above section will form a good representative collection of Dahlias at the present time.—D.

THE LATE MR. JOHN READ.

By the death of this well-known florist we of the older generation of florists have to lament the loss of an enthusiastic lover of the Auricula, Tulip, &c., and of one of those godly men who show that the truest lovers of Nature are those who in simple faith look up to their Father as the Creator and Upholder of all things; a Wesleyan, if I recollect right, and a consistent Christian, there are few who knew him who will not grieve to think that they have lost a friend of no ordinary worth.

It is now many years since that I paid Mr. Read a visit at Market Rasen. I had known him by his contributions to the "Gossip for the Garden," under the signature of "DERA," an anagram of his name, and I was very much astonished when I saw how small his collection of Auriculas was. His great delight was in the raising of seedlings, and in this he displayed no ordinary amount of intelligence and skill, carefully hybridising and keeping a note of all his crosses. He has left behind him two flowers which will probably perpetuate his name—Acme and Dr. Horner, both of which were sent into commerce by Mr. J. Booth of Failsworth, and is another instance of how strong a hold the Auricula has on those who cultivate it. Tulips, Ranunculuses, and other flowers were given up, but the Auricula remained to the last his chosen and favourite flower. He has left behind, too, what is far better, an honoured name amongst his relatives and friends.—D., Deal.

THE PARKS OF LONDON.—No. 2.

FINSBURY PARK.

As usual this charming little Park is in the most satisfactory condition, every portion indicating the care and attention which are so necessary to produce the best results. Well-kept turf and walks, fast-improving shrubberies, and abundance of flower beds serve to render the Park a greatly appreciated resort for the inhabitants of the contiguous and rapidly advancing districts, and it is surprising to observe the great number of people who assemble there every Saturday and Sunday if the weather be fine. One feature, too, which this of all the London public parks alone possesses is that its elevated position commands some pleasant prospects. Beautiful glimpses of Essex and Middlesex are obtained from the northern portion of the Park, where the ground slopes down rapidly. All these advantages render Finsbury Park

as deservedly popular in the north of the metropolis as Battersea Park is in the south. The flower garden is chiefly confined to a sheltered position near the lake at the highest portion of the Park, but numerous beds are found elsewhere, generally in lines on each side of the paths. All the beds are extremely bright, the Pelargoniums and other flowering plants being in first-rate condition, fresh, vigorous, and flowering profusely; but objection might be taken to the preponderance of scarlet and pink in the arrangements, which in one place is very noticeable. Otherwise the designs are tasteful, particularly of a few carpet beds, which although not largely represented are remarkably well done. In the principal flower garden referred to above, which consists of two series of beds cut out in turf separated by a broad path, the display is very satisfactory. The beds are in several rows on each side of the path. Those at the back on the north side are very large, circular in form, and occupied with Cannas in superb health, the margin being formed with Ageratums, Pelargonium Vesuvius, the pretty and effective lilac-coloured Lobelia Omen, and the outermost edge of Echeveria secunda glauca. Some beds between these have Centaurea ragusina and Verbena venosa intermixed. In the next row the beds have centres of Pelargoniums, comprising Mrs. Turner, a strong free-flowering variety with bright pink flowers in very fine trusses, and Rose of Allendale, another very good light pink variety. These beds are edged with Crystal Palace Gem Pelargonium and Lobelia Lady Macdonald, a form of strong habit and bearing pale blue flowers. In front of these are smaller beds, some containing centres of Pelargonium Theocritus, a very good rich scarlet variety of strong habit, a band of Centaurea ragusina, and a margin of Lobelia pumila magnifica, the effect being very pleasing. The beds near the path are circular and oblong in form, the former containing Alternanthera magnifica, paronychioides major, and the richly coloured A. versicolor edged with Veronica repens, Herniaria glabra, and Echeveria secunda glauca. The others consisted of the beautiful white variegated Pelargonium Princess Alexandra, Lady Cullum, and Macbeth, edged with Iresine Lindeni kept very dwarf, and Mesembryanthemum cordifolium variegatum. Some other beds contain Coleus Verschaffelti, very richly coloured, and edged with Robert Fish Pelargonium. On the opposite side of the path the beds are planted in a similar manner, with the substitution of a few different varieties of Pelargoniums. In other parts of the Park are some good beds of Dahlias, Palms, &c., all excellent but not calling for special mention. Great credit is due to the Superintendent, Mr. Cochrane, for the able manner in which the Park is conducted.

REGENT'S PARK.

We have in this Park an instance of the great difficulties attending flower gardening in unfavourable localities, even when a considerable amount of skill is brought to bear upon the subject. Regent's Park, or rather that portion of it at the south side which is devoted to bedding, is so closely surrounded by trees and houses that it is not surprising if plants do not thrive so well or appear so fresh as in more open positions. However, though there is a slight dullness of colour noticeable, particularly in the Alternantheras, yet everything has been done that is possible under the circumstances to render the beds attractive, and in several instances these efforts have been fairly successful. Carpet bedding, subtropical bedding, and the ordinary beds of flowering plants are represented, and many tasteful designs, especially of the first mentioned, are noteworthy. One in particular, a circular bed cast of the central path, has a most graceful design composed of a variety of curves combined in a highly artistic manner, and principally planted with Alternanthera amabilis and magnifica on a ground of Mentha Pulegium gibraltaria, and had the colour of the former been richer the effect could have scarcely been excelled. Another bed opposite that is also pretty, but somewhat formal, as the design consists of straight lines and sharp angles. Several ribbon borders are bright with lines of Pelargonium Waltham Nosegay, Pyrethrum Golden Feather, and Ageratums, while the vases are very effective. Some of these contain a great number of flowering plants, such as Pelargoniums, Fuchsias, Calceolarias, &c., the sides being draped with Tropæolums, and the base covered with Lysimachia nummularia. Large beds of Castor-oil Plants, Cannas, Solanums, and Eucalypti form important features in the arrangements, the glaucous colour of the Eucalypti contrasting strikingly with the darker plants employed. These few notes indicate the chief excellencies of the display, and it only remains to state that the general condition of the Park is admirable as regards the keeping of the turf, paths, and shrubberies.

HYBRID ODONTOGLOSSUM.—Mr. Bardney describes a hybrid Odontoglossum (see page 192). Is this only a supposed hybrid, or is it proved? Was it raised in this country? I understand

that no hybrid *Odontoglossum* has been raised. Can anybody tell me whether *Cattleya Mossiae* or *C. Loddigesii* was the seed-bearing parent of *C. Manglesii*?—SINGLE-HANDED.

THE following are the ROYAL HORTICULTURAL SOCIETY'S ARRANGEMENTS FOR 1881:—Certificates will be awarded to deserving new fruits, vegetables, plants, and flowers; and medals, supplied by the Davis Fund, will be awarded for meritorious productions exhibited at the meetings. The Fruit and Floral Committees will meet on January 11th, February 8th, March 8th, March 22nd, April 12th, April 26th, May 10th, May 24th, June 14th, June 28th, July 12th, July 26th, August 9th, August 23rd, September 13th, October 11th, November 8th, and December 13th, the chairs being taken on each occasion at 11 A.M. The Great Summer Show will be held from June 3rd to June 7th; the Rose and Pelargonium Society's Show June 28th and 29th; and the Exhibition of the British Bee-keepers' Association July 26th to August 1st; the Artisans' and Cottagers' Show August 1st; and the Evening Fête on Tuesday, June the 28th.

— ON Monday afternoon there was a slight but welcome shower of RAIN IN LONDON, the first that has fallen for twenty-nine days. The heat since the commencement of the month has been very oppressive, and on gravelly soils in the south of the metropolis the grass has quite a brown and burnt appearance. Red spider has also increased to an extraordinary extent on several forest trees, notably on Limes and Willows, and several trees of the former have lost all their foliage. The weather has been highly favourable for maturing the wood of fruit trees, but now that the harvest is secured a copious shower would be of great benefit to both farms and gardens in the south of England.

— "W. B." writes, "In Croxteth Hall Gardens there are now flowering in two beds *TIGRIDIA PAVONIA GRANDIFLORA* and *CONCHIFLORA*, and the effect is gorgeous. These beautiful plants are admirably adapted for planting in shrubby borders and in large beds in the pleasure grounds. The Plum trees in a house in the same garden, which generally do well, are again laden with a heavy crop of extra fine fruit. Pyramid Pear and Plum trees in pots, which have set the fruit indoors and afterwards been plunged outside, have a good crop of fruit."

— MESSRS. JAMES CARTER & Co., 237, High Holborn, request us to state that they will offer the second and third prizes in the open class A at the International Potato Exhibition to be held on September the 22nd and 23rd. The class is for twenty-four distinct varieties, nine tubers of each. Notice of a desire to compete must be given to the Secretary, Mr. J. A. McKenzie, Tower Chambers, Moorgate, London, E.C., before the 14th instant.

— WE are informed that the ROYAL HORTICULTURAL SOCIETY OF IRELAND held their autumn Show on Thursday the 2nd inst., in the grounds of Mr. Cecil Guinness at Dublin. The weather proved very favourable and the attendance was large, which with the satisfactory condition of the exhibits rendered the Show very successful. Plants were well shown, particularly those remarkable for their ornamental foliage, Ferns being represented by many handsome specimens. The chief exhibitors in these classes were Lord Ardilaun, St. Ann's, Clontarf; Sir Edward S. Hutcheson; Lord Justice Deasy; Messrs. Watson, Westby, Jury, Riall, and Wilson. Among the exhibits not in competition a fine group of plants from Messrs. Rodger, McClelland, & Co., Newry, was

noteworthy. Cut flowers were also numerous shown, the chief prizes for Dahlias being obtained by Mr. Leland, Mr. C. Hamilton, and the Rev. Frederick Tymons. Other exhibitors in the cut flower classes were Messrs. Guilfoyle, Berry, Comyns, Lindsay, Campbell, and Jonathan Hogg. Messrs. Alexander Dickson and Sons, Newtownards, also staged a fine collection of Rose blooms. Fruit was not comparatively quite so well represented as the other classes, but several exhibitors had good examples of Grapes, Peaches, Nectarines, Plums, and Pears. The chief prizes were awarded to the Countess of Charleville (Mr. Roberts), Lord Portarlington, and Mr. Nathaniel J. Powell.

— IN the Royal Horticultural Society's Garden at Chiswick a number of CAPSICUMS are now being grown for trial, a great variety of forms being represented. Among those with long narrow fruit two of the best are Red Cayenne (Veitch), and Long Yellow (Vilmorin et Cie.), the fruits of both being somewhat similar in form, 4 or 5 inches in length, and freely produced. Among the varieties bearing rounded fruits the most noticeable are Cherry Red, Yellow Tomato-shaped (Leroy), Yellow of Nocera (E. G. Henderson), certificated at the last meeting of the Society, Yellow Cherry (W. Paul & Son), and a very large-fruited variety named The Monster (E. G. Henderson). Of the small-fruited forms, Tom Thumb (Sutton & Sons) is the best; it is of dwarf habit, and bears a great number of diminutive fruits, the plant being really attractive in a decorative point of view.

— REFERRING to the letter, page 207, on SOUND AND DISEASED POTATOES, Mr. Luckhurst writes:—"Had 'W. G.' taken up the crop of Myatt's Prolific as soon as the tubers ceased growing, he would have saved it from disease. To leave this early variety to be lifted with Magnum Bonum—a late variety, was decidedly wrong, and the result is precisely what might be expected. If the early, intermediate, and late varieties are taken up separately in succession as the growth of each section ceases there will be much less risk of loss by disease."

— THE same correspondent writes as follows on *TROPÆOLUM SPECIOSUM*:—"This charming little South American climber has long been established in the open ground at Messrs. Woods' nursery near Uckfield. It is planted at the foot of a hedge some 6 or 7 feet high, over which its growth rambles every year, and is at the present time laden with clusters of its rich crimson flowers."

— THE very distinct and showy DAHLIA JUAREZII is now flowering finely at Mr. H. Cannell's nursery, Swanley, Kent, and he has recently exhibited flowers of it at several exhibitions, where they have invariably been greatly admired. Especially was this the case at the Alexandra Palace on Friday last, when they were shown with the brilliantly coloured *Tigridia pavonia* and bouquet Dahlias. The colour is so bright, and the starlike form of the flowers so attractive, that it deserves the attention of all who patronise the beautiful genus in which it is included. A botanical commendation was awarded for it by the Floral Committee of the Royal Horticultural Society on September 16th, 1879.

— THE *Southern Reporter*, describing a tour of the members of the Associated Chamber of Commerce, contains the following relative to the TWEED VINEYARDS:—"Arriving at Clovenfords the whole party inspected the Tweed Vineyards, which had been kindly thrown open for the day by Messrs. William Thomson and Sons, the proprietors. No visitor to this district should miss this sight, of which there is perhaps none similar in Great Britain, and certainly not in Scotland. The Vineyards are very large, and if the houses were placed in a line they would extend to the length of half a mile. An idea of their extent may, however, be much more easily gained when it is known that the annual production of Grapes is 15,000 lbs. or a little over 7 tons! Through the houses there run five miles of hot-water pipes, heated by twelve

boilers. This sight was certainly not the least attractive of the day, and to walk through the houses and view the luscious fruit hanging in bunches overhead within easy reach greatly exercised one's virtue, which, however, was rewarded on departing, for then the occupants of each carriage received a box containing a bunch of the tempting fruit of the Duke of Buccleuch, the total weight of the bunches being 112 lbs."

— R. L. writes as follows:—"The peculiar Orchid *BOLBO-PHYLLUM BECCARII*, of which Messrs. E. G. Henderson & Son exhibited a flowering specimen at the last meeting of the Royal Horticultural Society, though certainly not possessed of any qualities entitling it to the term 'gorgeous,' which has been somewhat strangely applied to it, is yet deserving of note from the extraordinary size of the leaves and the repulsive odour of the flowers. The leaf on the plant referred to was nearly 3 feet in length by about 2 feet in width, the small foetid flowers being borne in a dense spike. I believe this was the first time the plant has been flowered in this country."

— THE cultivation of TOBACCO IN FRANCE appears to be increasing. In the Department of which Calais is the principal town, this crop is said to be an important part of the industry of the district. Last year, in the Pas de Calais, 2100 acres were authorised to be planted with Tobacco, which was 247 acres more than in 1878; and this implies that both the Government and the agriculturists were satisfied with their previous experience. The amount furnished to the Government from this area was 3,659,636 lbs., or an average of 1743 lbs. per acre; and at the price which the French Government gives for the best quality, namely 1 franc 45 cents per kilogramme, the yield per acre would be about £24 15s. The quantity grown in 1879 was 573,196 lbs. more than in 1878. The Department of the Nord, another district with a climate closely corresponding with that of the south of England, grew rather more tobacco than the Pas de Calais.

— A NAPLES correspondent referring to the PHYLLOXERA IN ITALY says:—"It is reported from Messina that the invasion of the phylloxera is of greater extent than at first supposed. The Ministry has authorised the spending of another 10,000 francs, and decreed the destruction of more vineyards, on which work about three hundred men are employed. The proprietors are dismayed at the ruin with which they are menaced." The Government of Turkey has also forbidden the importation of any plants into that country, as a means of preventing the increase of the phylloxera in the Sultan's territories.

— WE received from Mr. Rivers during the last week of August a perfectly ripe, large, and handsome specimen of BEURRÉ DE L'ASSOMPTION PEAR, the quality of which was of great excellence. The fruit had been grown on a tree in a pot, and was placed outdoors in June. This is a much larger and earlier Pear than Williams' Bon Chrétien, and is highly worthy of a position on a south wall or other sheltered aspect, as it is undoubtedly the finest of all early Pears. It was raised in France by M. Rouille de Beauchamp, and first fruited in 1863.

— A DAILY contemporary in discussing the condition and prospects of the Fiji Islands under British rule, gives the following statement concerning the well-known COFFEE DISEASE—"The worst insect is the *hemeleia vastatrix*, which settles on the young Coffee shrubs. Some rash trader from Melbourne introduced the pestilent little grub, and now the British authorities are obliged to put plantations infested with this plague into strict quarantine, for fear of the infection spreading to other plantations." Possibly the writer of the above remarks will be surprised to learn that the *Hemeleia vastatrix* is a fungus, and not an insect.

— MR. JAMES CROSS of Bailie House, Wimborne, states that he planted in spring 1 bushel of CARTER'S IMPROVED MAGNUM

BONUM POTATOES, and he has just dug 28 bushels as the yield, none of the tubers being diseased.

FUNGI VERSUS DISEASE IN PLANTS.

THE contributions of your correspondent, Mr. E. Luckhurst, usually contain so much of practical interest and value to readers of the Journal, that in common with many others I generally derive no mean share of satisfaction and profit from perusing his remarks. It was, therefore, with a feeling of regret I found when reading his note on the shanking of Grapes in the last issue of the Journal, that our opinions regarding the relation of fungi to diseases in plants were entirely at variance. After referring to the fact that the Potato disease, Peach blister, and the shanking of Grapes have been attributed to the effects of fungi, Mr. Luckhurst states, "In every instance the idea is erroneous." He then draws attention to some well-known peculiarities of fungi, and observes that the diseased epidermis of any part of the young and tender growth of plants affords a suitable medium for the vegetating of fungus spores, and thence infers that fungi do not produce disease, but "follow and are the results of it." The only evidence adduced in support of this view is the somewhat doubtful fact that "delicate sickly human beings" are more subject to infectious diseases than "those in robust health," a rule which I am persuaded is by no means general; and further, the "analogy existing between plants and animals" is not of such a nature as to justify the argument. An intelligent and observant man like Mr. Luckhurst must, I am convinced, have other and better grounds for his opinion than the single statement referred to, and a further explication of his views would greatly favour myself and others who are interested in the subject.

The Fungi are an extremely large family, and the numerous forms differ very much in their characters; but there are two great sections into which they clearly fall—namely, those that grow upon the decomposing remains of organic matter, and those that grow only upon living beings, either vegetable or animal, and are true parasites. The latter, as with all parasites, possess the power of appropriating to themselves the substance of the being they infest, breaking up or decomposing the organic compounds, and thus obtaining the elements necessary for their growth. In the higher divisions of the vegetable kingdom parasites of various kinds occur, some with leaves and abundance of chlorophyll, which obtain from the host the rising or crude sap that is elaborated in their own leaves under the influence of the sun, while other forms, leafless and devoid of chlorophyll, subsist upon the descending or fully elaborated sap. The fungi resemble the latter in their action, for the whole of their support is derived from the living substance of the host, and when that dies the infesting parasite dies also. The conditions necessary to the growth of fungi are chiefly a particular temperature and moisture which vary according to the species, and without these conditions are provided the spores or mycelium of a fungus must perish, which much more frequently occurs from that cause than from the want of "a suitable nidus." Can Mr. Luckhurst bring into accordance with his view the fact that some parasitical fungi are entirely confined to particular species of plants?

I have not referred particularly to the Potato disease, which is undoubtedly one of the true parasitic fungi, nor to the Peach blister, or the shanking of Grapes, the connection of the latter with fungi being by no means clear, but to the matter generally, as did your correspondent after introducing his remarks with a few observations on the singularity of disease being so often attributed to the effects of fungus, instancing those above named as examples.—S.

SHANKING OF GRAPES.

I AM much obliged to Mr. Taylor for his kind and considerate letter on page 193 in reply to mine on the "Shanking of Grapes." Still I must entirely differ from him. It is not a matter in which I have come to a hasty conclusion, but the outcome of some years of close observation. When I said the Vines were healthy, I mean that they were all that could be desired in that way, and also I may say that the crop of fruit they were bearing was exceptionally fine; indeed I have never seen better, and this was also the opinion of others, as I can show. I sent some of them to Covent Garden Market, and my salesman wrote to say "that they were the admiration of all who saw them, and he could sell as many as I liked to send at very high prices." Well, some of these very bunches had little pieces shanked. They were cut off and carefully examined, and I am of the same opinion now as I was when I last wrote—it is caused by fungus. I am perfectly aware

that I am in opposition to the received opinion, but I cannot help it, and I feel confident that when the matter has been thoroughly investigated I shall be found to be in the right.

As regards Mr. Luckhurst's letter I have but little to say. With regard to certain diseases, if I may so term them, as resulting from fungus, he simply says, "in every instance the idea is erroneous." That is very easily said, but he gives no proof that it is so in any way. One assertion is equal to twenty denials is a well-known axiom, and this I apply to Mr. Luckhurst. His letter has no weight with me whatever. I think in the latter part he had better have consulted a medical man before he made the following statement:—"The fact of the liability of delicate human beings to suffer from infectious diseases while those of robust health are untouched, is well known to medical practitioners." Is it? Here is another of Mr. Luckhurst's facts. Now I believe it is remarkable that these particular kind of diseases, such as fever, small pox, &c., are more readily taken by persons in robust health, and are generally more fatal. Take, for example, the North American Indians, full of vigorous health; they were carried off in hundreds by small pox, and it is the same with fever. The old saying of "a creaking door hangs long on its hinges" is a truer one than most people think. Mr. Luckhurst goes on to say, "the analogy which exists between plant and animal life should fairly induce similar conclusions." I fail to see this entirely. The organisation of a man and a plant are so widely different that to my mind there is no analogy at all. As Mr. Luckhurst has so kindly said of my theory, I think I can more safely say of his letter—"in every instance the idea is erroneous."—HARRISON WEIR, F.R.H.S., *Weirleigh, Breckley, Kent.*

GLADIOLI, &c., AT LANGPORT.

WHEN a man—and he no scatter-brained smooth-faced youth, but a venerable white-headed sexagenarian—looks you quietly in the face and tells you that he has 20 acres of Gladioli, your first impulse is to give that low vulgar whistle which simply implies that your vis-à-vis has told you a pretty considerable tall one, or that Somersetshire acres are different in size from those in other parts of England. Your second is to think of the few hundred roots you have in your own garden, and to smile at the idea of your being thought to be a grower of Gladioli. Yet this was what Mr. Kelway told me when I met him at the Royal Horticultural Society's Show in June last, and bid me come and see. So on my journey to Taunton I accepted his courteous invitation, and, despite all the delays and inconveniences of the two competing lines of railway, was enabled to spend a few hours in visiting this most remarkable place, for the annals of Gladiolus-growing can tell of no such achievement as this. M. Souchet and his successors, Messrs. Soullard & Brunelot, grow them largely and supply the Continent with corms to a large extent from their grounds at Montreux and Fontainebleau, but they grow nothing like the quantity that Mr. Kelway does—a quantity that seems to increase every year; and I can quite believe his statement, that if his corms were planted the same distance apart that growers in their private gardens do, he has sufficient to plant 100 acres instead of 20. He may, then, surely lay claim to being the prince of Gladiolus growers.

Most florists know that Langport is in Somerset, but more particularly I may state that it lies on the branch line of the Great Western Railway from Yeovil to Durston on the main Bristol and Exeter line, in a tract of country of great historic interest—the scene of Alfred the Great's early life, and many centuries afterwards of Monmouth's rebellion, the last embers of which were so cruelly stamped out by the bloody assize of the brutal Jeffries. The country is low and marshy, but Langport itself stands in rather an elevated position as compared with the neighbourhood. The soil is of various characters—some light, other parts stiff clay, and others loam, so that no special advantages are derived by Mr. Kelway from his position, indeed I consider quite the reverse, for I saw on his land patches which had been continuously under water where the corms had perished—a marked contrast to Fontainebleau, where the clear bright autumn allows them to be lifted in such a ripened condition as is hardly possible in our moister climate; for the climate which ripens the delicious Chasclas de Fontainebleau must compare favourably in this respect to our own, where the ripening of Grapes out of doors is so rarely achieved.

Mr. Kelway's land comprises about 140 acres, and of this, as I have said, 20 acres is this year devoted to the culture of Gladioli. In such an immense culture there is, of course, to be found the utmost variety. There are huge patches of such as *Brenchleyensis*, *Bowiensis*, and the older French varieties; while there are selected spots where the choicer varieties both of French

origin and his own seedlings are grown, and the prices of the roots vary from 5s. a hundred to 60s. a piece. Here is a piece of ground, for instance, of several acres, where the corms have been literally ploughed in. The drills are done by the plough, the roots planted and covered over with the plough, much in the same way as Potatoes are in some cases planted; while here is another smaller piece where each corm has been carefully planted, and the ordinary garden method is adopted. He does not find that the soil makes much difference, and in this I am inclined to agree. Moreover, the use or non-use of manure does not seem to affect them. In the early days of Gladiolus-growing manure was considered injurious to them, and all were advised never to use it; this is an utter fallacy. I saw some small corms of the choice varieties, which were sown on an old hotbed, about 3 inches of soil resting on the manure, yet here they were as healthy as in any other part of the ground, while in other places a heavy coating of manure had been applied on the surface without in the least affecting the health of the plants, unless it was indeed to make them more vigorous. Wherever we turned it was "Gladioli to the right of us, Gladioli to the left of us," &c. Even the walks between the beds were covered with seedlings, and they seemed as much at home there as anywhere else. What, it may be asked, becomes of all these flowers? Do they "waste their sweetness on the desert air?" Not so; they appear in places all over England. Last year one hundred thousand spikes were sent out for decorative purposes to all parts of England, while America, the colonies, and the British Islands are largely supplied with the corms. It may well be imagined what a laborious matter this culture is. Already, when I was there, Mr. Kelway had begun the lifting of the small seedlings and spawn, and this will go on continuously for months as the corms ripen until frost comes to put an end to it. Then, again, consider the planting. Mr. Kelway takes off the outer skin of each corm, so that he may see that no imperfect ones are planted, and each has to be planted separately by hand. This planting begins in February, and goes on continuously until May or even June.

As Mr. Kelway grows such a large number of seedlings he has the good fortune to raise many very striking novelties, but it must be most bewildering for him to know what to reject. On my remonstrating with him for the enormous number of named sorts in his catalogue he posed me by the reply, "But what will you cut out? If you were to reply, The older varieties, the answer might be, Why Lady Bridport, one of the oldest, is also one of the best for exhibition purposes even now." But this makes the task of recommending varieties a very difficult one. Of course I know some, and can easily recommend them; but it does not follow that there are not many others quite as good and perhaps better. My advice would then be to anyone who desires to cultivate them, to name the price to which he will go and leave himself in Mr. Kelway's hands. In one respect my visit was unfortunately timed. The season was so very late that very few were in bloom, and it was with great difficulty that a presentable box could be cut for the Taunton Show; but had I been there in "the season" I daresay I should have been bewildered by the *embarras des richesses*, and so philosophically consoled myself.

Those who were present at the June Show at South Kensington need not be informed that Gladioli are not the only flowers for which Mr. Kelway is noted. The stands of Pyrethrums which he exhibited, and which so puzzled the multitude, bore witness to the fact that he is no ordinary cultivator of these fine flowers. I heard them called Chrysanthemums, Asters, and by one lady who was quite sure of her ground Zinnias. They were indeed very grand, and several of them were his own seedlings. Upwards of sixteen thousand of these very handsome plants were sent out last season. A notice appeared in the Journal some time ago of the large quantities of Hyacinthus candicans which Mr. Kelway grows. Bed after bed was filled with them, and upwards of twenty thousand blooming bulbs will be ready for delivery in October. It is a very handsome flower of the most dazzling whiteness, and the individual blooms are very valuable for button-hole bouquets; while planted in clumps in the borders it is very striking, and is thoroughly hardy. I had a small lot of seedlings in the ground all last winter, which bloomed very strongly this summer. Those who are now going in for herbaceous plants—happily an increasing number—will find this a very welcome addition to their border bulbs. It remains a considerable time in bloom, and supports its flower stems without the need of stakes.

Although Mr. Kelway cannot vie with some of our large growers of Roses as to quantity, yet in one department he is a large cultivator—Roses in pots, of which I saw some fifteen thousand, varying in size from 9 inches to 3 feet in height, exceedingly vigorous in growth and healthy. In the houses there were also some sights to be seen, the Cucumber houses especially, where immense fruit

for seeding purposes was being ripened off of his well-known and excellent varieties Conqueror, Paragon, &c. In one house I saw two thousand plants of the strange *Scolopendrium vulgare* var. *Kelwayi*. But after all one comes back to the startling fact—twenty acres of *Gladioli*! People make much of 12 acres of *Roses*, but that is mere child's play to this. No wonder that a stately building which I saw rising up should be devoted to the

drying of these corms, or that with pardonable pride at his success he should have called his house "*Gladioli Villa*."—D., *Deal*.

AQUILEGIA JUCUNDA.

THIS pretty species is well represented in the accompanying engraving, the neat rounded form of the leaflets, and the compact

Fig. 50.—*AQUILEGIA JUCUNDA*.

flowers with their short tubular petals and oval sepals, being faithfully depicted. It was regarded by Dr. Fischer, who first sent seeds to the Royal Horticultural Society about thirty years ago, as intermediate between *Aquilegia alpina* and *A. glandulosa*, both of which it resembles to some extent. *A. jucunda* is, however, dwarfer than *A. glandulosa*, and the flowers are of a brighter blue tint, which is pleasantly relieved by the petals being tipped with white. It is hardy, and may be grown in a well-drained border

of light soil, where it can be protected from excessive rains, which prove very injurious to it. Plants also succeed well on the rockery, where they must be freely supplied with water whilst growing, or they will not flower satisfactorily. The species is native of mountainous districts in Siberia.—R.

THE WOOD VETCH.—I have a word or two to say in favour of *Vicia sylvatica* as a border plant. A specimen in my garden is in

the form of a pyramid in a back row of a large border of plants, and is nearly covered with its charming silver-coloured flowers. By pinching-in the shoots it affords a grand display through the summer. It is by no means particular as to soil, good loam and decayed vegetable matter meets its requirements. It is easily increased by seed sown in the spring. There is another of our wild Vetches that is worthy of notice and a place in our borders. The Tufted Vetch (*Vicia Cracca*) is a charming plant when well grown. It requires confinement at the root. A large pot or other vessel should be sunk in the ground for it to grow in. It thrives in ordinary garden soil, and is increased by seed sown in the spring.—VINCIO.

WASPS.

A CORRESPONDENT asks how it is that wasps are so numerous this year, when they were comparatively scarce for two years before. Wasps are always numerous after a dry spring, and more especially a dry May. If the weather be wet and cold when they first appear a very large per-centage will die, but this year it would seem as if every one had lived. Hornets are later, and did not appear in large numbers till the wet month of June, consequently they are unusually scarce. It is surprising that wasps should be allowed to have their own way as much as they do, when a little organised resistance could scarcely fail to keep them in check. It is comparatively useless for one person here and there to pay a large sum for their destruction if the majority of people are apathetic till precautionary measures are of no avail, when they merely grumble at the nuisance and promise to do something next year. Those who do pay are liable to great imposition (which the many could in a great measure prevent), and at the most can only effect a temporary local benefit. If towns or districts would start some organisation for collecting queen wasps in the spring—and for the destruction not only of nests, but of the whole colony of wasps which belong to each nest, during the summer—some diminution of their numbers must soon be apparent. Should there be a dry May next year it will be quite useless for the majority of people to think of growing any outdoor summer fruit unless something is done to check the increase of wasps, for I can warrant there will be no scarcity of stock to start with.

If allowed I shall do the same as I have done for the last eleven years, and hope to be as fortunate as now in saving a considerable quantity of fruit; but again I say, Why do not everybody combine for the destruction of their common enemy? I pay 3*d.* for every wasp brought to me in spring till such time as the young insects come about, say the end of June, excepting when they are very numerous, and then half price is given. Sixpence is paid for every nest when all which belong to such nest are destroyed. If the insects are not past the grub state then the queen and the comb are sufficient for the money, but if any of the wasps have flown something more is necessary. The best way to destroy a nest and all its belongings when built in the ground is to fire a squib made with sulphur and a little gunpowder in the hole, and immediately stop it up to exclude the air and prevent the sulphur fumes escaping for a few seconds; then without loss of time dig out the nest, destroy its occupants before they have time to recover, and insert a wine bottle half filled with water in the place of the nest, so that the top of the neck may be level with the surface of the ground, and in or near the same place as the entrance to the nest was. The bottle must remain there for three days, and will catch every wasp belonging to the nest which may have been away from home at the time the nest was destroyed. Sometimes one bottle, although it will accommodate from seventeen hundred to two thousand, is not sufficient to hold all the rovers, and then it must be replaced by a second one. The bottles must be clean and have no scent with them, or the wasps will hesitate about entering. You may generally see, when a nest has been merely destroyed without any provision being made to catch the absent insects on their return, that it appears as strong as before it was disturbed, but not a wasp is to be seen after the third day when managed in the way I recommend. Sometimes a nest is so situated that a squib cannot be fired into it, and the comb cannot be removed, then I believe cyanide of potassium is the best thing to use; but as it is a dangerous substance with which I am not familiar I will leave the task of giving directions for its use to someone else.

Many people may think 3*d.* too much to give for a queen wasp, so it is if you can have it caught for less, and I have no doubt that school boys would gladly bring half a dozen for that sum; but it takes considerable skill to catch them, and I am afraid that if we left them all for the school boys many would escape; nevertheless a great many thousands might be caught by boys if clergymen and schoolmasters would move in the matter.

Understand that every wasp seen before the middle of June is a queen, and liable to have a nest of ten thousand at least. I lately estimated the number of cells in a rather large nest, and made out nine thousand of them. A great many of the young had flown, and fresh eggs were laid in their places, and I have reason to believe that there is often more than one succession of young insects from the same cells, therefore ten thousand is a comparatively small family.

I have this season to pay for 1192 queens, and this leaves out a goodly number killed by myself and family. About 230 nests have been destroyed within a mile of the garden up to the present time, but there is more than enough left for stock now.—WM. TAYLOR.

WASPS are quite a plague. Our late Gooseberries that we hoped to save are scooped out completely, and nothing in the shape of fruit escapes their voracity. Although we have destroyed a hundred nests within a radius of less than half a mile, and trapped a large number of insects in bottles and handlight traps, still they swarm in the fruit quarters. Having thrown some waste fruit away it was soon covered with wasps, and I tried the effects of a dose of nicotine soap; it had the effect of instantly killing most of them. This seems to me a more humane method of destroying wasps even than either bottles of sweetened beer or the torture of starvation in handlights, as by placing the garbage fruit in heaps the wasps may be destroyed in an instant by syringing with nicotine soap, 8 ozs. to a gallon of water, as hot as the operator likes to use it, or it will answer cold. A few heaps of fruit will attract the representatives of a wasp nest, and if the application is repeated they will soon be disposed of. Taking the nest is of course the most speedy method of destruction, and the other will dispose of the stragglers. Wasps will not touch anything impregnated with nicotine soap, therefore fresh baits must be used.—G. ABBEY.

SYRINGING PEACH TREES.

It is necessary to allude to the importance of syringing Peach trees after the fruit has been gathered in order to keep the red spider in check. An instance recently came under my notice where the leaves were entirely falling off prematurely through the red spider. The trees in question had evidently been neglected after the fruit had been gathered. This is a practice that is too common. It is not surprising that we frequently see puny fruit and sickly plants when subjected to such treatment. If cultivators who practise these systems knew the result consequent upon the treatment, they would preserve the foliage of the trees in a healthy state. This keeps the trees healthy and vigorous, and abundance of large fine-flavoured fruit is the result. The other plan rapidly impedes the luxuriance of the trees until at last they are exhausted, the trees become diseased and gradually die off, bearing, perhaps, for a few years poor ill-flavoured fruits. If water is freely employed at the roots and the foliage well syringed red spider will rarely appear upon the trees.—SCIENTIA.

A WEEK IN YORKSHIRE.—No. 1.

A WEEK spent in a county so large necessarily afforded no adequate opportunity for inspecting more than a few gardens, and those not the most extensive; yet in even small and moderate-sized gardens some good result or some suggestive hint may be found that is worth recording. A rambling horticulturist sometimes finds a garden or nursery in which some feature is especially prominent. Orchids, Grapes, Roses, or what not may be the strong point, and in these cases the work in hand is usually done well. Sometimes he finds a curious garden, such, for instance, as one having a greater extent of walks beneath the surface than above it, for such a garden surely exists. Sometimes he finds, not so much a curious garden as some novel practice, such as growing Grapes in a stokehole and subsequently seeing a prize eard attached to the bunches in a large exhibition and splendid competition; and sometimes he finds an extraordinary garden. As most readers have a preference for "something extraordinary" I will endeavour to describe my last "find" first. But I should never have found this remarkable garden without a guide. A kind friend sent me the following letter—"The story of the life of Isaac Holden was given in 'London Society' of February, 1879. He has been a wonderfully successful man in business, and now spares no expense in everything he takes in hand. His residence is in this neighbourhood, and a visit from you would not prove a disappointment. There are about forty glass houses all new. The winter garden has cost about £25,000, I believe, and covers nearly half an acre. The mosaic pavement took nine Italians about three months to lay, and Frenchmen were years erecting rockery. The roof of one house is covered with Tomatoes, and

the admiration and envy of every gardener in the neighbourhood. I know every place of note within many miles, but there is not one equal to Oakworth House; and should you think it worth while to come and see the place I shall be happy to communicate with Mr. Holden and make arrangements for going. Mr. Holden's house is well worth going through. The air is renewed every half hour, and temperature kept at 60°. Twelve large boilers are in use. The winter garden has sixty rows of 4-inch pipes, in addition to coils of pipes. I have so often read of visits to gardens in the *Journal* that I concluded to write you." This invitation was irresistible, and I found myself at

OAKWORTH HOUSE.

As the hot-water piping employed in an establishment is in some degree indicative of the extent of the glass structures, it may be well at the outset to publish a return under this head that I asked for and obtained. It is a plain unadorned statement by Mr. Holden's plain, practical, and industrious gardener Mr. Shaw. "The vineries contain 4000 feet of 4-inch pipes, heated by one of Weeks's and one of Lumby's (of Halifax) Paragon boilers. The other block of houses, containing Pine pits, plant-preparing houses, &c., are heated with the same kind of boilers, and contain 7000 feet of piping. The winter garden is heated by the horizontal tubular boiler, and contains 7500 feet of piping. We are having another boiler put in to assist in severe weather or in case of a breakdown—one of Keith's of Arbroath. The stoves, &c., adjoining the winter garden are heated by two of the horizontal tubulars (Byram's of Bradford), and contain 11,000 feet of piping." We have thus 29,500 feet of 4-inch piping in one private establishment. That is extraordinary enough, and especially when considered with the fact that the owner of Oakworth House once worked for as low wages as perhaps any gardener has done who reads these lines.

What a lesson this one life teaches! It shows what may be accomplished by unflagging perseverance and a dogged determination to achieve success. It shows the colliers' boy, once receiving the rudiments of education in a thatched cottage, and now occupying a princely home. It tells of his first earnings as "drawboy" to hand weavers, of his studies at night-school after 8 P.M., of his alternate term of work and school according as the means of his father permitted the latter, of his learning Latin and Greek and becoming a school teacher, of his studies in chemistry, of the great invention by which almost all the world benefits daily, yet not half the world knows to whom they are indebted for the simple yet important household necessity—the lucifer match. Others have reaped a rich reward in the manufacturing of this indispensable article, but to Isaac Holden belongs the honour of being the real inventor and first manufacturer as an aid to him in his night studies. As he explained before a Committee of the House of Commons the invention "cost him so little labour that he did not think it proper to get a patent, or no doubt it would have been profitable." The "story" above referred to informs us that after becoming a dominie in Scotland Mr. Holden, then a young man, was appointed book-keeper to a manufacturing firm. How he brought his inventive powers to bear in the improvement of machinery of wool-combing, how he pressed on and succeeded, founding three business establishments in France and one in England, and became the head of the greatest firm of the kind in the world, employing four thousand people, a number which equals the work of twenty-five thousand before machines were invented to do the work. Such is a bare skeleton outline of the career of this remarkable man, and his works prove he is good as well as great—a liberal benefactor to worthy objects, a hearty supporter of the religious denomination to which he belongs, a friend of the friendless, and a helper of the needy. Any notice of Oakworth House would be clearly incomplete without reference to its owner, and now having in the briefest possible manner given a faint idea of an extraordinarily successful career I will attempt a sketch of his home and garden.

Oakworth is a small village about three miles from Keighley. Its position is elevated, and overlooks a broad dale. In the hollow nestles Haworth, the goal of many literary pilgrims, for it was in her father's vicarage there that Charlotte Brontë wrote her name in history by the production of her famous work, "*Jane Eyre*." Beyond the plain are hills which meet the clouds, and the view is diversified and fine. Quite in the village of Oakworth—indeed, almost in a line with the cottages—is the Hall, the front of which is not more than 20 yards from the high road; but the cottages on either side of the mansion are masked, on one side in a remarkable manner. A fine Wesleyan chapel is the boundary of the forecourt on one side of the mansion, and on the other side a huge rockery, rises in bold and rugged massiveness above the tops of the houses, the effect being wildly picturesque. This huge pile forms a covered way to the back of the mansion, the

approach to which is through a cavern formed with blocks of gigantic size, and as rough and rude as if upheaved by some violent subterranean eruption. To subdue the effect of this great pile and to secure harmony of design immense stones half encircle the small panel garden, in which is a fountain, immediately facing the front portico, which has also a rock-like appearance; on the opposite side there is a rustic summer-house made with cement and flanked with rock, one cavernous approach leading to the chapel and another to the winter garden, the doors being faced with cement, and resemble solid stone; yet with all this stone the effect is neither harsh nor cold, for shrubs of upright and bush growth, low evergreens and trailing plants, have been freely yet judiciously planted, the result being a frontage which is unique of its kind, original in design, novel, striking, yet satisfying.

A glimpse between the chapel and mansion is obtained of the winter garden. A large dome of richly stained glass rises from the centre; there are also panels of stained glass on the sides near the roof, the spear-head-like ornamentation surmounting the spouting being gilded. The dome I understood was erected by Messenger of Loughborough; but the building—indeed, all the glass structures, with the mansion—was designed by Mr. Smith, architect, of Bradford, a relative of Mrs. Holden's, and executed under his supervision by local workmen. Externally this remarkable winter garden is rich and imposing, while internally its appearance is extraordinary. There are larger glass structures to be seen in a few public and private gardens, but none, so far as I am aware, like this in the manner of arrangement and ornamentation. As more space than can be afforded this week will be requisite for even a meagre description of this and the structures adjoining, further notes on Oakworth House must necessarily be postponed to a future issue.—A RAMBLER.

TRUFFLES.

I SEND you a tuber that I have dug out of an Oak wood, and have been informed it is eatable, but its perfume does not com-

Fig. 51.—Black Truffle.

mend itself to me. Will you kindly inform me what it is, and if I have been correctly informed respecting its edible properties? —A BERKSHIRE SCHOOLMASTER.

[It is a fine specimen of the Black Truffle, and is correctly represented in the accompanying figure. Truffles are regarded as a choice dish on the tables of the affluent. They are generally found in chalky or clayey chalk soils. Just as many aerial fungi only grow on dead wood, and that of a particular kind, so the black Truffle is only met with among the roots of trees, and more especially the common and Evergreen Oak, and *Quercus coccifera*. It is among the roots of these trees that the Truffles are most abundant, and acquire a perfume that makes them esteemed all over the world.

Truffles increase like other allied fungi. When ripe they contain minute spores not exceeding $\frac{2}{50}$ th of an inch in diameter, and when the Truffle decays in the ground these produce white threads,

or mycelium, like Mushroom spawn when running, and a fresh crop results.]

ESCALLONIA MONTEVIDIENSIS.

THIS is one of the most beautiful white-flowering shrubs that I have seen for some time. I recently saw a specimen in the gardens of Mr. J. G. Mitchinson, at Park Clies, Galval, where it is trained quite 10 feet high against the front of his house, and is just commencing to flower, and cannot fail when more extensively grown to become a great favourite. It is growing in common garden soil covered with about 2 inches of gravel. It has little or no water, and it appears to flourish luxuriantly, and has been for four or five years quite exposed. This is very remarkable, for in a garden adjoining that of Mr. Mitchinson, and belonging to T. R. Bolitho, Esq., the gardener (Mr. Every) cannot induce it to flower. Speaking of Escallonia I may also add a few remarks on *E. macrantha*. As a plant for making hedges this is unsurpassed; it will bear clipping almost to the main stalk, and the hedge at the thickest part need not be more than 12 inches through. Here, as well as at Scilly, it is used very largely for this purpose, and the fields where Potatoes are grown are usually divided into one-eighth and quarter-acre squares with it, thus protecting the Potatoes from the wind and taking up scarcely any room. *E. Ingrami* is a very fine species, but is not so accommodating as *E. macrantha*.—W. ROBERTS, *Penzance*.

VEGETABLES IN AUSTRALIA.

THESE have been scarce enough sometimes there, though not because they could not be produced. The first comers were glad enough to qualify their salt junk, salt pork, and ship biscuits, the only procurable food in the settlement. With no vegetables they seized upon the top shoot of a native tree, which ever afterwards was known as Cabbage Palm. As the Tea-tree Scrub gave them a bitter substitute for Bohea, so did other native plants render service for those sighing after vegetarian fare. Bushmen usually despised the pot, unless it were the pannican for their tea, and contented themselves with damper bread and meat for every meal. Thanks to the health-giving breath of Australia this fare did them no great mischief. There are many thousands of persons in Australia who are months at a time without vegetables. As shepherds or solitary miners they might easily grow them if they took the trouble. In American wastes men have the everlasting salt pork and Beans, but in Australia flour and fresh meat form the staple diet.

An impression once existed that Potatoes would not thrive in so hot a region as Australia. Finer than those raised in southern Victoria or the Darling Downs of Queensland cannot be found; and they are as cheap as they are good—far better and cheaper than in England. As to the Cabbage family, nowhere can such be surpassed. For Cauliflowers it is truly a native clime. The markets display magnificent specimens, and at a price to excite the envy of Britishers. The Chinese, to whom Australian gardeners are much indebted for improved culture, have introduced a Chinese Cabbage, which is much relished by miners everywhere. However outlandish a place be, occupied by Queensland diggers, a Chinese Cabbage vendor will find it out. Give the Yellowface the means of irrigation, and the most barren-looking bit of bush land becomes a garden of vegetables under his hand. The health of country residents has been decidedly improved by the advent of Chinamen with the variety and goodness of the vegetables they raise.

In Queensland climate and soil are suitable for the production of an extensive assortment for the table. Whatever can be grown in any part of the world has a chance there. The plateaus of the southern districts bring forth plentiful supplies of English Potatoes, Cabbages, Lettuces, Parsnips, Carrots, Turnips, Beet, Celery, Endive, Seakale, Rhubarb, Spinach, Onions, Leeks, Cauliflowers, Parsley, Asparagus, Peas, and Beans. These, too, obtain a flavour only to be realised in a sunny land. Their richness and ripeness put them out of comparison with the watery varieties found in Britain. Then, again, upon the rather lower lands, even in the more settled fields around Brisbane, Ipswich, and Maryborough, almost the whole of the English vegetables do equally well, with the addition of those not to be grown in the British Isles. Further north, toward the seacoast or beside the inland streams, genuine tropical vegetables may be procured. Thus it is that the colony contains the entire range of them.

Yams and Sweet Potatoes have been introduced with the Taro from the South Sea Isles and are getting popular. The tuber of the West Indian Yam will often run down a yard in Queensland. There are also the Chinese and South Sea sorts of Yam. Roots of 30 lbs. weight give abundance of nutritive food, very acceptable

in hot countries. The pods of the Okra are good in soups. Maize is there, as in America, used as a vegetable when in a growing state. Melons, Marrows, Pumpkins, Squashes, Cucumbers, Tomatoes, and many other varieties are successfully cultivated. Cassava, Tapioca, and Arrowroot, growing there in such luxuriance, come hardly under the denomination of vegetables, though so agreeably diversifying the table of Queenslanders. But the Sweet Potato, so mealy and rich, is pre-eminently the root-crop of semi-tropical farmers, and is as valuable for human food as for all kinds of stock. Not only may as much as twenty tons of roots be taken per acre, but about that quantity of capital green food. The very heat, of which some immigrants complain, helps to make Queensland one of the most favoured lands for vegetables.—J. B.

ANNUALS FOR SPRING.

ANNUALS for spring must be sown in autumn, and annuals for summer must be sown in spring. Where an ounce of seed of any of the popular forms of these pretty flowers is sown in the autumn a pound is sown in the spring. This would imply that if sown in spring the display produced is generally the most satisfactory, and that resulting from sowing in the autumn correspondingly disappointing. Yet annuals well selected, sown at the right time in the autumn, and properly managed, are in every respect far superior to those sown in spring—superior in vigour of plants, size of flowers, and continuity of beauty. Why, then, has not the plan of sowing them in autumn become more popular? That is a very natural question not easy to answer. Possibly there are some people who do not desire to have their flowers early, but prefer to devote the whole of their resources to producing a grand display in summer. This fashion, however, is generally dying out, and there is a disposition now to have gardens like the fields, woods, and waysides—cheerful as early in the year as possible. There are also a certain number who have tried the plan, perhaps once, of sowing annuals in the autumn, and did not succeed as they expected, therefore abandoned the practice and did not “try again.” This is not the way to succeed. Seasons vary, and all alike are not favourable to these flowers when sown in autumn any more than they are for Wheat, fruit, Potatoes, or any other crops.

A quarter of a century's experience in growing annuals enables me to say positively that those sown in autumn and rightly managed are as certain to succeed, and more likely to give satisfaction, than the same varieties sown in spring. True, they are not alike good every year, but they are invariably good enough to be greatly admired, and I sow the seed annually with at least as much confidence of securing a satisfactory return as I do of securing a crop of Cabbages from seed sown a month previously.

The present is precisely the time for sowing seed of some of the most useful hardy annuals; and if immediately these notes appear—there must not be a day's delay—those who intend sowing order the seed promptly, and sow it the same day it arrives from the seedsman, they may hope to succeed in their object. Many people include Forget-me-nots in this category, because they are raised from seed and flower with the annuals in early spring. They are charming flowers, but it is no use ordering seed of any of them and sowing it at the present time. June, as has been mentioned in the Journal, is the time for sowing Forget-me-nots, then strong plants are provided before the winter. Such plants are fine in spring, but plants from seed sown in the autumn are weedy and very disappointing; therefore do not waste money on Forget-me-not seed now.

Among the most reliable of annuals for spring decoration are *Silene pendula* and its variety *compacta*, the latter being charming for pots. August is the best time for sowing, but they succeed fairly well sown now, and may be included in the seed order. For a glowing mass of pink in May, June, and early July nothing can surpass and few plants equal *Saponaria calabrica*. This is preferably sown towards the end of August, but succeeds well sown now. The white variety makes a pretty edging, but is not so robust and hardy as the pink. *Nemophilas* cannot be sown at a better time than immediately these notes appear. Those who have not seen a bed or mass of the blue and white varieties of *N. insignis* in mixture in May have a treat in store. *N. maculata* is pretty, but scarcely equals those named, and all of them are extremely attractive in pots in the conservatory in April. *Venus's Looking-glass* sown now will produce rich masses next May that cannot be equalled by any other plant of its colour, and the flowering sprays are most beautiful when cut and associated with other flowers in vases. The winter seldom injures this plant, and the slugs have to be hungry before they eat it. *Clarkia pulchella* in the red, white, and parti-coloured varieties are amongst the most effective of plants for large beds and mixed borders in May and June, and the present is the exact time for sowing. The Tom Thumb forms are the most effective, especially those with broad petals and semi-double flowers. For

masses or lines of yellow, or rather yellow and white, the gay *Limnanthes Douglassi* is suitable, and is about as hardy as any weed that grows. About the end of August is the time for sowing, but it will do very well sown now. *Viscarias* are among the most attractive of annuals, and sown at the same time flower with the *Clarkias*. *V. oculata* is the most constant, but *V. cardinalis* is richer. *Viscarias* are seldom destroyed by frost, but excessive wet is sometimes injurious. *Collinsias* are extremely fine in May onwards. They cannot be sown at a better time than the present; if sown earlier they make too much growth before winter, and are then apt to be injured by severe frosts. The same remark applies to *Larkspurs* and *Candytuft*. As a dwarf bright blue flower for early spring *Veronica syriaca* is pretty, and the pink and white *Virginian Stocks* are dwarf and cheerful. Other annuals might be named for sowing at the present time, but those mentioned will suffice for rendering a garden attractive in spring and early summer.

As to sowing—select an open position, and the further it is from old walls, hedges, and such green crops as *Broccolis*, *Seakale*, and *Rhubarb* the better, for it is there that slugs hide, and they will travel some distance for some of the delicate annuals. The soil should not be too rich, and if rather firm so much the better, as the object must be to induce a hardy and sturdy, not a free and succulent growth. Sow in drills a foot apart; if the present dry weather continues saturate the drills before sowing the seed, which cover very slightly with fine soil. The moment the young plants can be seen run the hoe through the soil frequently, as this not only prevents the growth of weeds, but is a greater check to slugs than many people imagine. Immediately the plants can be handled thin them out so that each plant stands singly, and at the least an inch from its neighbour. The plants then become hardy, and branch out and become vastly superior to those left to crowd and choke each other in the seed beds and patches.

If slugs commence their attacks dust the plants with fresh lime an hour after dark when the molluscs are feeding, and more execution will be done than by twenty dustings in the daytime after they have enjoyed their repast and retired to their haunts.—SPRING GARDENER.

KITCHEN GARDEN.

THE crops of Winter Spinach will by this time require thinning, and it should be done before the plants become too large, allowing sufficient space between them to prevent damping in bad weather, and keep the surface soil between the rows well stirred. The latter observation applies to all growing crops at this season, the whole surface in the kitchen garden being hoed. Thin out autumn-sown Onions to about 3 inches distance apart. Every alternate plant may be removed in spring as required.

Cabbage.—As a spring crop this is one of the most important in cultivation. Place plants from the July sowing in their permanent quarters without delay; ground that has been occupied with Onions, turned over and properly prepared, will be suitable for this crop, planting from 15 to 18 inches apart every way. Do not allow the plants from the August sowing to stand too thickly in the seed beds, but when fit prick off the required number, and thin out the rest. A batch of the latest of these plants should be pricked off in beds for spring planting. Prepare the ground for the main crop of Cabbages, the plants being placed out 18 to 20 inches apart.

Attend to the requirements of Cauliflower plants from recently sown seed and sow again. Take up the main crop of Onions, and let them be exposed for a few days before storing them away thinly in a dry room on shelves, tying the larger in bunches so that they can be removed to a cooler situation in February. Keep up a good supply of salading. Select fine dry days for tying up Lettuce and Endive. Examine plantations of Globe Artichokes, cutting away useless stems, and removing all decayed leaves, so as to admit light and air to ripen them at the base. Tomatoes require some attention now; the leaves should be removed where they shade the clusters of fruit in order to advance the ripening, also keeping the laterals closely pinched or removed. Where means are at command a first sowing of Dwarf French Beans should be made in pots, placing them in a house with a

night temperature of 55° to 60°, and as close to the glass as possible. Osborn's Forcing is the best variety for this purpose.

FRUIT HOUSES.

Vines.—The earliest forced Vines should now be pruned if the wood be brown and hard and the leaves turning yellow. The house and Vines should have a thorough cleaning, washing the woodwork with soft soap and water, and the glass with clear water, the Vines being well brushed over with a solution of soft soap, 1 lb. to a gallon of water, removing the loose bark only, and repeating the dressing if insects have been troublesome, adding half a gallon of tobacco juice to the above mixture, with a small quantity of flowers of sulphur. The woodwork should be painted, and the loose surface soil removed, supplying fresh turfy loam and a sprinkling of crushed bones. Any Vines in an unsatisfactory state may be improved by partially lifting the roots, removing the old soil and carefully laying the roots in fresh compost, but this must be done before the fall of the leaf. Vines in pots intended to be started in November ought now to be fully ripe and at rest. The soil should be kept comparatively dry, but must not be allowed to become dust dry, or the plants will be much injured at the roots. Later batches of pot Vines should now be turned outside, and have the canes secured to walls or other exposed situations. Young Vines that have made strong growth will take a long time to ripen, and should be aided with fire heat, continuing it with a free circulation of air until the wood is brown and hard, discouraging any further growth by removing the laterals as they show. Continue fire heat for late Grapes until they are thoroughly ripened, ventilating the house top and bottom. The outside border must after this be protected from heavy rain by means of shutters, tarpaulin, or any similar material, as the Grapes keep much better when the roots are not chilled by heavy autumn rains. Ripe Grapes should be frequently examined, and all decayed berries removed.

Peaches and Nectarines.—The leaves will be off or nearly so in the earliest forced house; and to induce as complete a rest as possible the ventilators should be constantly kept open, and if the lights be movable they may be withdrawn for a time, which will prevent undue excitement of the buds and have an invigorating tendency, especially as the border will become thoroughly moistened by the autumn rains. If the lights cannot be removed see that there is no deficiency of water at the roots of the trees, for though the impression prevails that dryness at the roots accelerates ripening of the wood, it is fatal to the development of the buds. The border should never be allowed to become dry at any time, but of course a much lessened supply of water will be necessary when at rest than during growth. When the leaves have fallen the trees may be finally pruned. Only the strong growths that have not the points well matured should be cut back. In all cases be careful to cut back to a wood bud, not being deceived by a triple bud, as these in some instances form triple fruit buds, notably *Noblesse* and *Grosse Mignonne*. Thoroughly cleanse the house; and if the trees have been infested with red spider or other insect pests dress the trees at once with an insecticide, as red spider will secrete itself in the rough portion of the bark and in the woodwork. Nicotine soap, 8 ozs. to a gallon of water, at a temperature of 100° to 120°, will destroy every kind of insect, it being applied thoroughly but carefully with a brush. If the trees are badly infested it may be necessary to repeat the dressing before they are secured to the trellis. Remove the surface soil of the border, and supply fresh loam having an addition of bone dust and wood ashes in equal proportions to the extent of about a twentieth part. Partial lifting of weak trees and renovating the borders will be necessary, which should be done before the leaves have fallen, and in the case of trees that do not ripen the wood well the roots should be carefully lifted and relaid in fresh compost near the surface, ascertaining that the drainage is efficient. Do not neglect trees from which the fruit has been gathered in the succession houses, thinning out growths not required for future bearing, removing the bearing wood of the current season, ventilating freely, watering inside borders as may be necessary, and occasionally syringing the foliage. Late trees swelling off fruit will need the borders moist and mulched, and those with the roots in outside borders must not be neglected should dry weather prevail, and if carrying heavy crops weak liquid manure should be supplied. When all the fruit has

been gathered and the wood not being in a favourable condition as to ripening, gentle fire heat with a free circulation of air will be advisable, which more particularly applies to the late varieties; the midseason Peach trees will ripen the wood if the autumn be favourable, but if wet and cold they are benefited by gentle warmth and a free circulation of air.

PLANT HOUSES.

Orchids.—In the East India house the temperature should still range from 75° to 85° by day and 65° at night, which should be maintained until the end of the month, when a gradual reduction will be necessary. Give every encouragement to *Aërides*, *Phalænopses*, *Saccolabiums*, and *Vandas*, the blocks, baskets, or pots being damped every morning, and in the afternoon of fine days a syringing overhead will be of great benefit, but care must be taken not to render the sphagnum or peat soddened. Shade as little as possible—only sufficient to prevent the sun scorching the foliage. Encourage *Calanthe vestita* and vars. *Veitchii* and *Warneri*, also *Limatodes rosea* to make large pseudobulbs, for the stronger these plants are grown the finer will be the flower spikes. They should have a maximum of light, and be supplied with weak liquid manure. Too much light cannot be had in the *Cattleya* house henceforth, therefore dispense with shading, and clean the glass both inside and out, it being important that the growths be well ripened before winter. *Lælia purpurata* and *Cattleya Mossiæ* may be repotted if necessary, and should be kept in the warmest part of the *Cattleya* house to enable them to complete the growths as soon as possible; but forward plants of these which have completed their growth should have an increased ventilation; and *Cattleya citrina*, *Lælia albida*, *L. acuminata*, and *L. majalis* should be thoroughly exposed to the sun. Thorough cleanliness is of the greatest importance in Orchid culture, therefore sponge the leaves frequently, thrips and aphides being readily and safely destroyed by dipping the plants in a solution of 2 ozs. or 3 ozs. of nicotine soap to a gallon of tepid rain water, being careful that it does not reach the roots, and washing it off in about a quarter of an hour with soft water at 90°. The present is a good time to repot *Odontoglossums*, *Masdevallias*, and *Oncidiums*, giving them fresh pots, baskets, or blocks as may be necessary, employing a compost of equal parts sphagnum and fibry peat, with a sprinkling of charcoal and small potsherds. The pots must be clean, and should be drained to a depth of two-thirds, covering with a layer of sphagnum, potting moderately firmly, and keeping the base of the plant a little above the rim of the pot. Any plants not in a satisfactory condition should be carefully cleared of the old compost; remove the dead roots, and place the plants in pots just large enough to hold the roots, keeping the atmosphere as moist as possible, and carefully supplying water at the roots until re-established.

Stove.—The warm weather at the beginning of the month may induce some to retain flowering stove plants in conservatories longer than usual; but although the days are warm the nights are becoming cool, and if the plants remain in such quarters very long it must injure them for future flowering considerably. When moved to the stove care must be taken not to excite them into growth, as they will naturally be disposed to do in the higher temperature, seeking to prevent this by withholding water, but not so as to injure the foliage. The temperature should now be gradually reduced; and although stove plants do not require a long season to rest, no time is better for it than during the three closing months of the year. Fire heat will only be necessary at present to prevent the temperature falling below 60° at night, and to keep it at 70° to 75° by day. *Allamandas*, *Bougainvilleas*, and *Ixoras* that were started latest into growth will continue flowering the longest, and as flowers are now valuable the plants should be kept at the warmest end of the stove. Shading, except for tender fine-foliaged plants, should now be discontinued, and thoroughly cleanse the glass both inside and out. Tuberous-rooted *Gesneras*, *Caladiums*, *Gloxinias*, &c., as their leaves become discoloured and evince signs of ripening should have water gradually withheld, keeping them in a light airy position in the stove. *Gesneras* of the *zebrina* type should be kept well up to the glass and have copious supplies of weak liquid manure at every alternate watering, similar remarks applying to *Tydas* for winter flowering, also *Begonias*, as the stronger they are the finer will be the flowers.

Winter-flowering plants generally should have liquid manure in preference to increasing the size of the pot, and keep them near to the glass, the object being to produce compact growth.

NOTES ON VILLA AND SUBURBAN GARDENING.

Pruning Hardy Fruit Trees.—It is now getting late for the summer pruning of fruit trees, and those who have not performed this operation should no longer delay. Young standard trees of any kind should have the growth thinned out if at all crowded, but do not shorten-back that retained. Pyramidal and bush-shaped trees of either Apples, Pears, Plums, or Cherries, Morellos excepted, that have grown to the required size, and are fruitful, should have all the young growth cut back to about the fourth joints, but the younger trees that are being formed only require to have the growth thinned out where crowded, cutting to near the fourth joint, the shortening back of the remaining shoots being delayed till the winter. Hard pruning is very unadvisable where a tree is vigorous and unfruitful, as it only induces the formation of still stronger growth in greater quantities. A better practice is to thin out and leave a few strong shoots unpruned distributed throughout the tree. An Apple tree treated in this manner in 1878 is this season clothed with Apples in a manner resembling ropes of Onions. If this plan fails to make a tree fruitful, then root-pruning must be resorted to, and the present is a good time for this if not performed too severely. Standard Morello Cherries have this season been most profitable, in fact they seldom fail to bear well. The growth of these may be thinned-out if crowded, but it must be borne in mind that the next crop will be taken from the present season's growth.

Wall trees of the above kinds of fruit may be treated much the same as above advised for the pyramids. Trees having covered their allotted space to be rather closely spurred back, and the younger trees to have all leading shoots, and any required to fill up intervening spaces as the tree extends and spreads, laid in full length. Apricots to be treated similarly, but the young growth of Peaches and Nectarines for next season's crop requires to be laid in thinly. Outdoor Grapes are a failure this season, owing to the badly ripened state of the bearing wood. To avoid a recurrence of this failure, freely thin out the growth, and lay in a few shoots at intervals on each side of the main rods, stopping those with bunches to a joint or two beyond these, and those without to be left about 12 inches in length. Lay in young growth where old rods have failed of late years to bear well, and stop leading canes if weak to about 18 inches, and if strong to about 3 feet. To assist the maturation of young Raspberry canes, cut out all the old canes (those that fruited this season), and thin out the young canes if at all crowded. Keep the runners of both old and young Strawberry plants closely pinched off, and during dry weather give the plantations of the latter an occasional watering. Weeds to be kept down by frequent hoeings, choosing bright days for the operation.

VINERIES AND GREENHOUSES.

Grapes.—Keep all lateral growth stopped to a single joint at each time, and give abundance of moisture at the roots, especially where the borders are of very limited extent. The fruit ought now to be ripening fast, and the earlier in this month it is ripe the better in every respect. If it is later than the middle of this month, the probability is that it will be of indifferent quality, owing to the failing solar heat being of insufficient strength to properly elaborate the requisite amount of sugary matter, and without which Grapes will not keep well. To assist the ripening give more air both during the nights and days, and maintain a drier atmosphere. Grapes will not ripen properly in a cool house crowded with plants, and as a matter of course quickly decay under such conditions. Hence the necessity, previously alluded to, of forwarding them as much as possible in the earlier stages of growth, in order to have them ripened, cut, bottled, and stored away in a dry room before the winter occupants of the house are brought in from the open. Many amateurs' houses are imperfectly ventilated, so that air cannot be given in sufficient quantities in the usual way. Every house ought to be so arranged that air can be admitted at each light, both at the front and highest part of the roof. Much may be done in badly ventilated houses by opening the doors on warm sunny days.

Wasps and flies are remarkably busy among the fruit of all kinds this season, and have a great partiality for ripe Grapes. They may be kept off by enclosing the bunches in muslin bags; but this has its disadvantages, and a better plan is where possible to stretch scrim canvas, hexagon netting, or other similar material across the rafters or stanchions as the case may be, wherever there are ventilators, by these means excluding the pests. Seltzer water bottles, and failing these soda water or other wide-mouthed bottles half filled with a mixture of beer, water, and sugar, are wonderfully attractive to wasps and flies, and oftentimes if hung in good numbers in a vinery will save the crops. They should also be hung on the Peach, Pear, and Plum trees if the crops are of any value.

Fuchsias are now very effective in the greenhouse, and to keep them so as long as possible attend well to the watering, giving weak liquid manure often. The same remarks apply to Coleuses, which however are not of much good in a cool house later than September. Torenias Fournieri and Bailloni as they lose their flowers may be thrown away, as they are really annuals. Gloxinias and tuberous-rooted Begonias as they cease to flower should be gradually dried off at the roots, to be eventually stored away on a dry shelf. The same treatment should be given to a few plants of Begonia Weltoniensis to be saved for next season, the remainder to be thrown away.

Keep the flowers pinched out of the plants of Chinese Primulas, and shift the smaller plants into the flowering pots, and keep the frames somewhat closer till established. Give abundance of air to the largest and well-established plants. Cease to pinch back the plants of Salvias, Eupatoriums, Browallias, Abutilons, Heliotropes, Salvias, and other winter-flowering kinds, and shift into larger pots any that may require it. Keep trained Mignonette closely pinched back, and still prevent Zonal Pelargoniums from flowering, and let them have all the sunshine possible, and they will then give abundance of bloom during the earliest part of the winter.

Striking Bedding Pelargoniums.—As was anticipated much difficulty is being experienced in striking the choicest varieties of these; owing to the very succulent growth made whole pans of variegated sorts have decayed at the base, and that too before any water was given. Where long enough they have been cut afresh and placed in the sun for two days previous to being again inserted. All cuttings taken off late were served the same, and the pots and pans when filled were at once placed on sunny shelves under glass, and no water given for at least a week.

TRADE CATALOGUES RECEIVED.

Francis and Arthur Dickson & Sons, 106, Eastgate Street, Chester. — *Catalogue of Bulbs.*

The General Horticultural Company (Limited). — *Catalogue of Bulbs.*

Hooper & Co., Covent Garden. — *Catalogue of Bulbs.*

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Book (S. M. W.).—We quite understand the subject of the book of which you desire the title, but so many works are incidentally alluded to in articles that we are unable to find the one you need unless you can suggest a nearer date, or can state the subject of the article in which the book is mentioned. We have endeavoured to find what you want, but have failed in our search. If however, you can aid us by a further suggestion we will readily search again.

Exhibiting Araucaria excelsa (T. C. Smith).—It is a greenhouse evergreen tree, and cannot properly be excluded from a class for "stove and

greenhouse plants" any more than can Palms, which are also either stove or greenhouse trees.

Mildew on Gooseberry Leaves (A. S.).—There have been insects on the bushes as on other trees adjacent, and where these abound glutinous matter is invariably found on the foliage, and this is often taken possession of by a fungus, as in the leaves you have sent. If these are a fair sample, the fungus will do no harm to the bushes; but if other leaves are much more infested, dust them with fresh lime or sulphur.

Pruning Raspberries (Idem).—It is an excellent plan to remove the old canes from Raspberries at this season, and also to remove superfluous growths, but the canes remaining must not be cut to the height required for fruiting next year. You may remove the tops of any that are very tall, and further shorten them after the leaves have fallen, but topping the canes now is not essential.

Exhibiting Zonal Pelargoniums (San Juan).—We are unable to answer your question, but if you write (enclosing a stamped directed envelope for reply) to Mr. Cannell, Swanley, Kent, who was a large and successful exhibitor at the show you name, he will either be able to answer your question or give you information of equal value on the subject to which it pertains. We are glad your show was so successful.

Conifers Unhealthy (X. F. Z.).—Many Conifers were much injured by a sudden and severe frost that occurred last November, and then the protracted and almost arctic winter following caused the death of many specimens, also of shrubs in various districts. We have no doubt whatever that your trees and shrubs were injured by the frost. Your gardener appears to have done all that is possible to restore them, and we are unable to suggest any further remedy.

Vines for Planting (Old Subscriber).—If you will state what your object is in growing Grapes—whether you require a supply of good Grapes over a long period, or as many varieties as you can cultivate, or a heavy crop of easily grown Grapes all ready at the same time, we will endeavour to answer your question. You must also inform us whether you have made preparation for growing those Grapes that require a hothouse temperature to produce them in fine condition. You afford no data whatever to enable us to give a reply that will be useful to you.

Cutting down Cordyline australis (J. Mackenzie).—As your tree is healthy it will in all probability push forth fresh growths at any point at which you may cut it down. We have seen specimens cut down to the ground, and they have grown again freely; occasionally, however, we have known them when cut down "sulk and die." We would not hesitate to cut down a healthy specimen, and by syringing the stem frequently we should expect fresh growths to issue in due time.

Dividing Alpine Plants (T. J.).—Some of the plants you name are liable to damp off when divided in the autumn, especially if heavy rains occur and are continued more or less through the winter. A safer time for dividing and replanting would be just when fresh growth is commencing in the spring. The Heaths may be repotted now, if they need repotting, and the work must be done with great care. There is much danger in overpotting these plants, especially if the work has to be done and the plants managed by amateurs.

Fruit Trees on Grass (Busy).—If the trees have attained a good size, are healthy, and grow freely, they will probably sustain no injury by permitting the grass to grow close to their stems; but, on the contrary, may bear more freely, but the fruit will not be quite so fine as before. If the trees are at all weakly and stunted a mulching of manure or dressing of rich soil would be better than a covering of grass over the roots. You will now have no difficulty in determining the question. We are unable to reply more explicitly, as you did not state the age, size, and conditions of the trees. Your other question shall be answered in a future issue.

Insect on Cineraria Roots (W. Copeland).—The woolly insects to which you refer had quite shrivelled in transit, and were not recognisable; the brown grubs were probably conveyed to the pots in the soil or manure employed in potting. We should first try the effects of clear lime water as used for expelling worms from pots, and if this has not the desired effect should have recourse to paraffin. But this must be used with great caution. We have found that half a fluid ounce mixed in a gallon of soapy water has destroyed the aphides on Lettuce roots without injuring the plants, but we are unable to say if paraffin at that strength could be safely applied to Cinerarias. Try it of different degrees of strength with a few plants that you can afford to sacrifice, and carefully note the effects a week afterwards on the roots and aphides, obliging us with the result of your experiments.

Scale on Vine Leaves (T. M. C. Lincoln).—The leaf sent is much infested with scale, not mealy bug, and the insects being on the upper surfaces of the leaves are not easy to destroy; indeed the only safe plan you can adopt is to wash them off with a sponge and strong soapy water—a rather tedious process, and we think not absolutely necessary if the Grapes are ripe or cut, and the foliage is approaching maturity. We would not permit the leaves to remain until they drop off, but after they have fairly assumed their autumnal tint we should take them off by hand, leaving the footstalks to ripen and fall naturally. If you do this, and burn the leaves, you will destroy the bulk of the insects. Prune early and scrub the rods thoroughly with a strong solution of soft soap—5 or 6 ozs. of soap to a gallon of water, to which may be added half a pint of tobacco water, using it as hot as can be borne by the hand. Wash also the woodwork of the house, cleanse any plants that may be in the structure, and if the border is inside remove the surface soil to the depth of a few inches and add fresh compost. If you carefully carry out these suggestions you may possibly succeed in extirpating an injurious pest. A sweet glutinous substance is generally present on leaves where scale abounds, and it is this that attracts the flies to which you refer.

Lopping Trees (A Gardener).—It is always desirable to endeavour to remove grievances in an amicable manner. Probably if you courteously inform your neighbour of the injury you are sustaining by the overhanging branches of his trees he will aid you in removing them. If he ignores your complaint you had better write and inform him that you intend on a certain day to cut off the overhanging branches, and that you will be glad of his presence or that of his representative on the occasion. If he takes no notice of this intimation you will be justified in cutting off the branches, but you must be careful to cut them only where they actually hang over the fence; also prune them in a neat workmanlike manner, so that there is no splitting or splintering of the wood or tearing of the bark below the parts at which the branches are severed. You cannot then be accused of doing undue injury to the trees.

Ficus elastica Unsatisfactory (J. B.).—The plant has lost its lower leaves either by the soil having been too dry at some time, causing the roots to shrivel, or too wet, causing them to decay; or possibly the room was too cold at

night during the winter. Many plants were greatly injured last winter by the latter cause. You may adopt the plan you propose of striking the top, and possibly you may succeed. The pot should be so placed that the base of the lowest healthy leaf is covered with soil. Turfy loam, peat, and leaf soil in equal parts, with abundance of sand and crushed charcoal, will be suitable, and must be kept constantly moist. Established plants and Palms will grow well in a compost of turfy peat with a third of leaf soil and a sixth of sand and small lumps of charcoal. Your question on the cost of heating is unanswerable, as so much depends on the apparatus and position of the house, and much more on the character of the weather. You cannot have anything better than a mixture of ordinary house coal and coke as fuel.

Red Spider on Melons (*Subscriber*).—If the Melons are on a trellis and you can syringe the under sides of the leaves you may dislodge a great number of the insects and benefit the plants. The water should be directed with as much force as possible to the foliage without injuring it. If you cannot syringe the under surfaces of the leaves you must sponge them with a solution of soft soap and tobacco water of the strength that has so often been recommended in our columns, or 4 ozs. of nicotine soap dissolved in a gallon of water will answer equally well. Syringe the Passiflora violently with the same solution, or a thorough washing with pure water will be of great benefit. The moisture will not do the slightest harm to the Grapes if you ventilate the house freely, employing a little fire heat if necessary.

Mildew on Grapes (*S.*).—The berries were much rubbed in transit; still traces of mildew are apparent, but we think it will disappear if you employ fire heat, as it will certainly be to your advantage to do, and ventilate the house carefully. We do not think that mildew is the sole cause of the injury to the berries, but having employed no fire heat the moisture has condensed on them at night, then on opening the ventilators possibly a little too wide and a little too late in the morning evaporation has been sudden and excessive, and hence the "specks and shrivelling." Lady Downe's Grapes in the state that yours are should have a night temperature of 65° with the top ventilators opened an inch all night. Before the temperature increases to 70° in the morning admit more air, and continue opening the ventilators wider in advance of the increasing temperature until the front and top lights are thrown wide open when the temperature approaches 85°. Examine the border a foot or more below the surface, and if the soil is at all dry give a heavy watering. You may damp the house once at midday, but it must be dry in the afternoon when you commence closing the ventilators. With this treatment intelligently carried out we think the crop will ripen satisfactorily; but if the mildew does not disappear dust the parts affected with sulphur, which can be blown off again in the course of three or four days with a pair of bellows.

Early Harvest Apple (*Ramallo*).—The above is the name of the Apple of which you sent us three specimens. As showing the importance of submitting adequate examples of fruit sent to be named, we may state that any one of the three sent, so much do they vary in form and outline, would have been rather difficult of identification, but the three examples rendered the matter easy. The following is the description of this Apple as recorded in the "Fruit Manual," and which you will find agrees with the majority of the fruits gathered from your tree. "Fruit of medium size, 2½ inches wide, and about 2½ high; round. Skin smooth and shining, pale yellowish green at first, but changing to clear pale waxen yellow as it ripens, with a faint blush of red next the sun, and set with imbedded white specks, particularly round the eye. Eye small and slightly closed, set in a round and shallow basin. Stalk half an inch long, inserted in a rather shallow somewhat russet cavity. Flesh white, tender, crisp, and juicy, with a quick and pleasant sub-acid flavour. An estimable and refreshing early dessert Apple of the first quality; ripe in the end of July and the beginning of August. The tree is a healthy and free, though not a vigorous grower, and an abundant bearer. It is well adapted for dwarf or espalier training when grown on the Paradise stock, and ought to find a place in every collection however small. Though of American origin, this variety succeeds to perfection in this country, a qualification which few of the American Apples possess."

Potatoes (*A. S.*).—1, We presume the gentleman, whom you do not name, either renders the shed frostproof in winter or removes the Potatoes to a place of safety. That is what we should do. Potatoes are ripe when the skins are firm, but the tubers will keep well if dug up before they are ripe, the disease being absent, for thilpy spread in a dry place they soon form firm skins. 2, Potatoes have attained their "proper eatable size" when the foliage turns yellow in the autumn; but to evade the disease some cultivators dig their Potatoes as soon as the tubers have attained a good size, whether the haulm is green or not. When taken up before the skins are set, the tubers, especially of the later varieties, are not immediately in good condition for use, but they improve considerably by keeping, and eventually become of fair quality. 3, As to the period of use, much depends on soils and seasons. From one garden, and there may be many such, we have had Magnum Bonum of excellent quality in August; grown in another garden the tubers are not good until they have been kept for some months. We had some old tubers of excellent quality on the 12th of July, but they had been kept 4 feet below the surface of the soil in dry brick pits. Early Rose grown in dry soils is good as soon as the foliage decays naturally, and continues of the same quality for several months, and the same remarks apply to Paterson's Victoria.

Roses for Buttonholes (*R. D., Liverpool*).—No Roses are equal to the Teas for this purpose, but Moss Roses are often acceptable. Hybrid Perpetual Roses are too large, Général Jacqueminot being perhaps the most useful, and we think fifty plants of it would be more profitable than one plant each of any fifty varieties that could be selected. Teas, however, are the most suitable, and it will be better for you to have a number of plants of a few varieties than a large number of varieties represented by one or two plants each. For roofs and walls grow Maréchal Niel, Gloire de Dijon, Madame Trifle, and Cheshunt Hybrid. Near walls and in other positions grow Niphetos and Isabella Sprunt in large numbers. Madame Falcot, Lamarque, Madame de St. Joseph, Marie Van Houtte, Safrano, Mons. Furtado, and Catherine Mermet are also suitable. Some others may be equally good, but we have already named too many, as those who grow buttonhole Roses for sale find it to their advantage to grow few varieties. A number of the Tea Roses should be grown under glass, the others in the open air, to be protected if needful during the winter months. Some of the most hardy of the Teas are Madame Berard, Bouquet d'Or, and Madame Bravy. Mrs. Bosanquet is also suitable for outdoor culture, and the white Boule de Neige and Baronne de Maynard afford a profusion of white flowers, but not tea-scented. They will succeed well in your soil on the Manetti stock. Your other questions will be answered next week.

Name of Fruit (*Mrs. Edwards*).—The Grapes were smashed flat in coming through the post and were beyond identification. Fruit should never be sent in paper boxes, but in tin ones.

Names of Plants (*W. W. A. Nairn*).—*Alchemilla alpina*. (*K. T.*).—We

never received worse specimens for naming—single flowers thrown loosely in a dry box with no foliage. The *Thunbergia*, however, is *T. alata*. No one can name the *Mesembryanthemum* without seeing a fresh spray with foliage as well as flowers. (*A. Parkin*).—1, *Mesembryanthemum tenuifolium*; 2, *Rudbeckia Newmanni*; 3, *Plumbago capensis*. The flowers were admirably packed, and arrived as fresh as when cut. Wet moss was tied round the stalks, and the bunches placed in a small tin box and made firm with a little slightly damp moss. (*Subscriber*).—1, *Scolopendrium vulgare cristatum*; 2, *Adiantum cultratum*; 3, *Selaginella Willdenovii*; 4, *Onychium japonicum*; 5, *Neottopteris australasica*. (*K. H. H.*).—The portion of a frond you sent is not sufficient to enable us to judge of the habit of the plant, but it appears to be *Adiantum formosum*. (*E. M.*).—1, *Armeria maritima*; 2, *Sedum spurium*; 3, *Potentilla recta*; 4, *Achillea Ptarmica flore-pleno*. (*J. Begbie*).—*Campanula rotundifolia*. (*Miss L. Bailey*).—1, *Enanthe fistulosa*, common Water Dropwort; 2, *Antennaria margaritacea*, Pearly Everlasting American Cudweed; 3, *Lythrum Salicaria*, Purple-spiked Loosestrife; 4, *Lysimachia vulgaris*, common Loosestrife. (*C. A. Locke*).—The specimen with small leaves is *Fuchsia procumbens*, the other is *Lysimachia vulgaris*.

POULTRY, PIGEON, AND BEE CHRONICLE.

THE CULTIVATION OF LUPINS.

LUPINS are of three varieties, indicated by the colour of the flowers, which are yellow, white, and blue, and are well known in our gardens. They are cultivated as fodder plants extensively in Germany, France, and Belgium, the yellow variety being considered the best, because it throws more leaves in proportion to the stems. It is mostly seen in northern Germany and Prussia, where it is considered important for use in the green state as fodder, and for the seeds, which in those countries come to perfection. It is esteemed by the farmers there because it will thrive upon the poorest sands, upon which no other leguminous crop can be grown. We have not grown either variety, but our neighbouring farmers have at least tried the blue-blossomed variety. We will first allude to the policy of growing it at all, for upon the poorest sands there is no crop to compete with it; but still we must consider that these soils may be made useful in some other ways, such as the planting of Larch or other Firs. If, however, produce for stock is required Gorse may be grown, which will yield a considerable amount of produce as food for dairy cows, horses, &c., as described in this Journal, September 18th, 1879. It is also true that light sands may be laid into pasture, but cannot be made to yield a profitable crop under ordinary management, especially in very dry summers. The home farmer, being unlike a tenant occupier of the land, can therefore choose the crops and the style of farming best adapted to the soil and climate which he has in hand. It is said that this crop is only adapted to light soils, but we have seen large and abundant crops of green fodder produced upon strong soils. On heavy land it may be ploughed-in as a green crop, and the analysis shows that the haulm of Lupins is well calculated not only to manure the land chemically, but mechanically also, owing to the enormous bulk, said to reach in favourable seasons from 16 to 21 tons per acre. This quantity of luxuriant haulm ploughed-in—the same as Mustard, &c., is often done—for manure cannot fail to answer a good purpose upon every variety of heavy land. The only point seems to be that a fine tilth, the nearest approach to sandy land in condition, is really necessary.

Dr. Voelcker's essay, in the "Journal of the Royal Agricultural Society for 1860," on the composition of the yellow Lupin, and a soil suitable to its culture, gives an analysis of the composition of yellow Lupins cut down in a green state. There is about as much water in Lupins cut down green as in the Cabbages. The amount of mineral matter is likewise nearly the same in both, but the proportion of albuminous or flesh-forming matter is greater in Lupins than in Cabbages. The seed required for this crop should

be obtained from Germany, for in our climate the crop is found to ripen unevenly, and in some late seasons does not produce seed of sufficient ripeness for use except to a small extent, particularly as the seed always ripens irregularly. The seeds of the first flowers begin to ripen when the top of the plant is still blooming, and for that reason the plant must be cut before finishing its growth. On seeding the land the seed should be drilled or dibbled in rows at about 20 inches apart, so that the weeds may be killed by the horse hoe. Mr. Thos. Crisp of Butley Abbey, in a letter to the Council of the Royal Society, says, "My attention was first directed to the growth of the Lupin by Baron Herm. von Nathusius of Hundisburgh in Prussia, who in 1856 was kind enough to give me two bags of seeds—one of the blue, the other of the yellow variety, which I planted upon what is here called poor blowing sandy land, and the productiveness of the plants greatly surprised me. In 1858 I drilled about 1 bushel per acre of seed upon 18 acres of poor land, from which I obtained fifty waggonloads of sheaves. The luxuriance of this crop quite astonished all that were acquainted with the sterility of the soil, and the quantity of grain before harvesting was estimated by various persons at from 40 to 50 bushels per acre." Mr. Crisp goes on to say that "In a letter I received from the Baron, December 18th, 1858, he states 'that we have had here (in Prussia) the most unfortunate season I ever remember. We have lost all our Clover layers by excessive dryness, and the Lupins are the only crops which can help our sheep through the winter. It is really a valuable plant for some soils. I had a field of 36 acres drilled with blue Lupins in May after the Clover plant was lost, and one of my neighbours offered me 57 bushels per acre for the 36 acres, which I refused. In my letter I omitted to state that the yellow Lupin is the better for hay, straw, or chaff; but the blue is generally more productive of grain.'" Mr. Crisp closes his letter by stating, "My past success I think fully justifies me in commending the cultivation of these Lupins to the notice of occupiers of light sandy soils, to whom I believe it will hereafter prove of immense advantage. The Baron Herm. von Nathusius further states that the seeds are sown about the end of April or beginning of May, but not earlier, for it is found that the sharp night frosts are destructive to the young plant; the vegetation is also slow in the first weeks, but it soon becomes very rapid. If any rain falls the plants grow to the height of 4 feet, and a great quantity of beautiful flowers cover the whole field. There may be some conditions when the crop may be used for 'green manuring' as it is called, but generally it is a much better plan to fold off the plant with sheep, which not at first, but after they have been accustomed to it, are very fond of the yellow Lupin in the green state, and thrive remarkably well upon it. After being sufficiently dried the blue Lupin makes most excellent hay for sheep. If harvested for the seed the same plan as for Beans will answer best if the pods are mostly ripe and the crop intended for thrashing. The seeds of both varieties form very superior food for sheep, lambs, and fattening wethers. After they had been accustomed to it I have often seen them refusing cake if they had plenty of Lupins. The straw and chaff is excellent for store sheep. It has been found by many persons that Lupin hay, straw, and corn are in some degree preventives of the rot, and even sometimes remedial if the disease is not far advanced, owing probably to the bitter taste, which is an astringent and tonic. We know of no other plant which, generally speaking, is so peculiarly adapted for sheep. The seeds have been used for horses and cattle, and it is found profitable to mix them with Oats or Beans. Some farmers begin to give Lupin meal with milk to the weaning calves, and they are said to do well. But swine generally refuse them. The following is the result of an analysis of the air-dried seeds:—Water, 14 to 15 per cent.; nitrogenous substances, 33 to 36; fatty matter, 6 to 7; starch, sugar, &c., 26 to 30; woody fibre, 11 to 12; mineral matter, 3 to 4 per cent. We learn from this analysis that the Lupin seeds contain a greater percentage of nitrogenous substances than any other of our leguminous plants, so that their high value is fully confirmed by science. The cultivation of the Lupin is rather new, although many thousands of acres are now to be seen. There is no doubt but it is a real boon for the occupiers of the poorest sandy or gravelly land. Chalk and calcareous sand seem not to be favourable for it, nor wet and undrained land." There are other sorts of Lupins, particularly those from Egypt, which are cultivated in Sicily, and show a most luxuriant growth, but will not ripen except in a hot climate.

Mr. J. W. Kimber of Tubney Warren, Abingdon, in a letter to Dr. Voelcker gives some useful and interesting observations relating to his culture of Lupins in the adverse season of 1860, and states that "My farm consists principally of a soil commonly called a light-blowing sand of so fine a nature that high winds

very much disturb the surface in dry weather, which sometimes does injury to young plants, especially to Turnips; I therefore in 1860 manured a field with ten two-horse cartloads of pig manure per acre, and ploughed under. On the 3rd of April the Lupins were drilled 13 inches apart; $1\frac{1}{2}$ bushel of seed per acre. In the first six weeks the plants made but little progress, yet by the 1st of August they were just beginning to bloom, and had a most luxuriant appearance with a mass of yellow flowers, and continued in this state until the time of weighing the crop, September 24th, when two portions were weighed—one producing at the rate of 16 tons 2 cwt. 56 lbs. per acre, the other portion 21 tons. 12 cwt. 16 lbs. I think the Lupin crop will prove valuable on light sandy soils, where there is a difficulty of growing large crops of the ordinary farm plants; and I can express a favourable opinion of its feeding value, having had some sheep penned upon a portion of the crop; they made good work, eating all but the main stems. I also fed four yearling heifers whilst on pasture, being supplied with a quantity every morning, on which food they soon improved greatly, the pasture not being sufficient for them." After giving this information from both practical and scientific men, we can only say to the home farmer that in the event of his having land adapted for the Lupin—although he may hesitate to attempt their growth largely either as food for sheep or as manure for ploughing under—there is no reason why experiments upon a small scale should not be made, taking into consideration fully the foregoing statements upon the subject.

WORK ON THE HOME FARM.

Horse Labour.—In the southern and eastern counties the busiest period of harvest work is over, and in some of the midland and northern districts the harvesting of grain will be sufficiently forward for work on the land to be proceeded with. Where it cannot be yet done by the horses, if the corn has been cleared the Wheat stubbles should be commenced upon by steam power. Every day now is of the utmost consequence in preparing the land by autumn culture for the Barley of next year, and also for the Potatoes and root crops, especially the Mangold for seeding next spring. As the land is more than usually foul with couch grass and weeds this year, it is quite impossible to effect all the autumn fallowing required by horse labour alone without trespassing upon the seed time and preparation for Wheat. With steam power there will be no difficulty, for upon all those farms where steam machinery is available and forms part of the dead stock on the farm the work may not only be well forwarded, but it will also relieve the horses of the heaviest of the work, allowing them to proceed with the preparation for the green crops. When we have a dry time very few slugs will be found to injure the Trifolium if sown now by harrowing, dragging, &c., at the time of sowing only, with plenty of seed, not less than 25 lbs. per acre. When, however, the seed time is longer deferred, or the weather is wet, the land should be ploughed and seeded immediately after the plough in order that the rain may not interfere with the work. On the chalk hill farms preparation for the Wheat-sowing is usually made early, therefore the dung may now be laid out on the Clover leas, and the land ploughed and pressed as fast as the dung can be spread.

Hand Labour.—This will yet be required in connection with harvest work in the later districts. Potato digging, too, must now be done whilst the weather is dry; and generally speaking the late varieties will shortly be ripe enough to plough out. It is a good plan to put them away whilst the weather is dry; but in case they show any disease we find it a good plan to make a temporary heap covered with straw adjoining the spot whereon it is proposed to secure them for the winter, so that at the middle of October they may be examined and the heap made up to remain for the winter, being properly thatched and carthed over before the frosts commence. Some of the best covering materials are long strong grass and fern cut together from the woods or plantations, but where it can be obtained there is nothing resists frost like fresh seaweeds laid on next the tubers. The cattle now fattening in the boxes or stalls, the former being preferable, will be eating the last cutting of Clover, Saintfoin, &c. As soon as these are used up Cabbage comes in, if they have been grown to follow in succession. In some cases, however, in a season like the present, with a good plant of Clover in the Wheat or white Oats harvested early and the land in high condition, we have found the Clover grow up very quickly and strongly, furnishing a good cutting of green fodder on to November, or until cut down by frost. We find that it does not injure the Clover in future, it being better for the early spring growth than where folded off by sheep, as they often eat off the crown buds of the Clover plant too closely, whereas they are preserved without injury when the crop is cut with the scythe.

The sheep will now be feeding off early Turnips upon those farms where the practice is to sow Wheat afterwards, and if the roots are cleared away early enough it is a capital preparation for Wheat. For this system to answer the land should be dry and friable, so as not to suffer by the treading of the stock in wet weather. We have occasionally seen Mangolds fed off in this way by folding sheep on them in the months of September and October, the plan being to pull the Mangolds and allow the roots to lie on the land and become tough, and they are then better for the sheep. More care is, however, required,

as a much smaller bait of Mangolds is requisite for fattening sheep than of common Turnips, Cabbages, &c., and also a larger portion of cracked Beans or Peas should be used at first until the animals become accustomed to that sort of food; it will then be found that sheep will fatten faster upon the Mangolds than upon Turnips. This is the season for the flocks of Hampshire Downs to have the rams running with the ewes, and it is important if we wish to know the result of stock derived from certain sheep that they should be ochred with different colours. The earliest Dorset ewes will be now heavy in lamb, and must be fed and cared for accordingly. In various respects in purchasing these ewes whilst pregnant it is desirable to buy them and get them home if possible without going to the fairs, and also by drifting instead of by railway carriage, as these ewes never do so well as when driven, although near to lambing.

TOY PIGEONS—THE JACOBIN.

NEXT to the Fantail there is none of the Toy Pigeons more universally known than the Jacobin. Its quaint hood and chain have been the delight of most of us in childhood; its gait is elegant and attractive, and it is a docile and tameable bird. There is much difference in this respect in the dispositions of Pigeons. Our favourites the Archangels, agile and beautiful as they are on the wing, are somewhat shy in the loft and aviary, but the Jacobin soon becomes confident. It is one of the oldest fancy varieties, and the descriptions of it given by the writers of the middle of the last century are good even of the present type of Jacobin. There then seems to have been a very similar though separate variety—the “Rough”—which was superior in one of the Jacobin’s properties—viz., “chain,” but inferior in others, especially size, for it was a large bird, whereas the Jacobin should be one of the smallest of Pigeons. The two breeds were unfortunately much crossed, and in all probability the Jacobin has in consequence never recovered the diminutive size which was once one of its chief beauties. As in the case of other varieties, so with this, we will not attempt to improve upon good descriptions, but will quote one written 115 years ago—“The true Jack is a very small bird, very little bigger than a Tumbler, and the smaller it is the better. It has a range of feathers inverted quite over the hinder part of the head and reaching down on each side of the neck to the shoulders of the wings, which forms a kind of hood something like friar’s, from whence it takes the name of Jacobin, the fathers of that order wearing hoods to cover their baldness. Therefore the upper part of this range of feathers is called the hood, and the more compact these feathers are, and the closer they are to the head, so much the more the bird is valued. The lower part of this range of feathers is with us called the chain, but the Dutch call it the cravat, the feathers of which should be long and close, that were you to strain the neck a little by taking hold of the bill the two sides should fold over each other, which may be seen in some of the best.”

To enumerate the points of the Jacobin one by one, the head should be small and round, face and beak short, eye pearl; the colour of the head white down to a line from the beak to the eye. When the white extends below the beak towards the throat the bird’s appearance is much spoiled. The hood should fit as closely to the head as possible and be well rounded; badly shaped hoods often run up into a peak. The hood externally is of the general colour of the bird with no white visible, but on the other hand the colour must not run into the white head. Faults in the accuracy of this marking are very common, and here it is that the inexperienced should look out for trimming. The chain is, as it were, a continuation of the hood, and should be as long as possible. There is difference of opinion as to its form. According to the older fanciers the curling feathers seem merely to have turned one way—viz., towards the breast; they now generally turn also towards the back, and those which so turn are called the “mane.” This makes another point—viz., the “rose,” or spot from which these curling feathers radiate on all sides. There are still some fanciers who much dislike the addition of these more modern properties of the mane and rose. The distinction between the two “fancies” can hardly be explained without the comparison of living specimens. It has always seemed to us to some extent a difference of words, for many Jacobins will appear at one time to have a mane, at another to be devoid of it, according to their position and attitude.

As to colour the head of Jacobins is, as we have said, white; the tail and flights are the same. The rule as to the latter point is not so strict as with Turbits and other breeds, for Jacobins showing some colour in the flights are often seen in the show pen. The colour of the thighs is optional; for our own part we prefer them coloured to white. The ordinary colours of Jacobins are red, yellow, and black, all of which we find very rich in this breed. Blues are pretty, but are now very rare. There are also whole or self-coloured Jacobins; these are not attractive and are

generally coarse, save the white ones, which are very pretty, and when good in points very valuable. For information to the young fancier we may say that such almost always are spotted with red in their youth, and only become pure white after several moults. The Jacobin is fairly prolific, but highly bred birds are generally bad mothers and nurses, and their eggs must be entrusted to foster parents. Another warning, too, should be given: The breed is, as we said, very confiding and, from its hood, not quick of sight; it therefore easily falls a prey to cats. Jacobins when good all round will always fetch a high price, and even fair specimens if really good in certain points are of some value.—C.

THE CREWE POULTRY SHOW.

THE Show of the Royal Manchester, Liverpool, and North Lancashire Society opened at Crewe on Thursday in last week and continued till Monday night—far too long a time for poultry, specially for chickens of the year, of which it entirely consisted. It is always interesting to see the early produce of the year, and as this Show is the first of importance at which young birds are alone eligible we think it worthy of a general notice. This time last year we were struck by the great mediocrity of chickens in general except Dorkings, which through the summer always seem to benefit by plenty of rain; this year, on the contrary, all breeds are good, and especially so the Asiatics, which in 1879 failed. We doubt if taken all round we have ever in the first days of September seen so fine a collection of chickens as those in the show tent at Crewe.

Dorkings.—The dark cockerels were an even lot in size; nearly every one of them had some one fault, and so no bird won easily. We did not like the fifth claws of the first; second was white-legged and pretty; Messrs. Smyth’s bird was in many ways the best in the class, though his comb was ugly; their first pullet was a good bird, large and short-legged; Mr. Darby’s second, good in colour. In the other Dorking classes a very superior White cockerel was first, a fair Silver-Grey being second; a good Silver-Grey pullet first, though she looked a little wry-tailed, and a large White second.

Spanish were few. The first cockerel had a long healthy face; the first pullet was the only good one in the class.

Cochins were all round certainly good classes. As usual Mr. Sidgwick’s were extraordinarily forward; the first Buff cockerel and pullet were fully worthy of their exhibitor’s fame for early birds. The former was an extremely thick and well-feathered bird; the second and third cockerels too were good, but not so massive and forward. The first pullet was very even in colour; the second short-legged and fresh-looking. The first Partridge cockerel was a remarkable young bird, son we heard of the celebrated 60-guinea cockerel last year; the second cockerel was square and very massive, younger than the first, but a little spoiled by a light eye. The first Partridge pullet was forward and the clearest in pencilling. The first White cockerel was forward and very fair bird, a little yellow; the first and second pullets were both capital birds with little to choose between them. We admired a Black 640 (Badger).

Brahmas.—The first Dark cockerel was a grand bird, such as we have not seen for a long time, square, short-legged, and densely feathered, and by no means at his best yet. The first and second pullets were beautifully pencilled but narrow, and to our idea poor in form. The first Light cockerel, good in colour but heavily hocked; second, neat in shape and not hocked; third, younger, very good in colour. The first pullet was very handsome in shape and beautifully white, but not yellow enough in legs to please us; second, too much hocked. We failed to see the awards in most of the later classes, as we visited the Show on the first day. The Hamburgs looked good all round, the Blacks being particularly forward. In Polish, first in both classes were White-crested Blacks. We thought the first cockerel’s crest too much divided and dropping; we much admired the second cockerel of the same breed. The first pullet was very forward, the second a good Silver. In the variety classes the first cockerel was a Malay, the second a Black Minorca. First in pullets was a Plymouth Rock, second a White Leghorn, and third a Malay. The heat on the first day of the Show was almost insupportable in the tent, and the birds seemed to suffer a good deal. Their general quality was such as to excite expectations of some fine exhibitions in October and November.

POULTRY.—DORKINGS.—Grey.—Cockerel.—1, E. T. Herdman. 2, A. E. W. Darby. Pullet.—1, J. A. & M. P. Smyth. 2, A. E. W. Darby. 3, T. Briden. Silver-Grey or White.—Cockerel.—1, O. E. Cresswell. 2, W. VARIETIES.

THE BIRMINGHAM POULTRY SHOW.—We have received the schedule of the Birmingham Show, which this year will begin on November 27th. The general classification is little changed, except that all the cocks of all the sub-varieties of each breed come first and all the hens follow, instead of each sub-variety of all ages and sexes being arranged by itself. The chief new feature of the schedule is the addition of two challenge cups, value respectively £50 and £30, the former for the best Black Red Game cock of the year, the latter for the best pullet of the same variety. Any exhibitor who wins one of these cups three years out of seven will retain it as his absolute property. Polish, again, are well off with twelve classes. In the classes for Pigeons we can see no important change from late years. We observe the name of Mr. M. Leno among the Judges. We fancy it will be the first time that he has officiated at Birmingham.

— **BATH AND WEST OF ENGLAND SOCIETY.**—At the Council Meeting of this Society held at the Grand Hotel, Bristol, on Tuesday last, H. G. Moysey, Esq., in the chair. Mr. Knollys, in accordance with previous notice, brought up the question of Stewards and officers of the Society exhibiting in competition for prizes, and moved a resolution affirming its inexpediency. Considerable discussion took place, it being asserted by various members that the principle had always formed an acknowledged but unwritten rule of the Society, although precedents of occasional exceptions were quoted. Mr. Acland having seconded the resolution, an amendment was moved by Mr. Moore-Stevens, but afterwards incorporated with the original motion, and the resolution was finally passed in the following terms:—"That it is inexpedient that Stewards and officers of this Society should exhibit in competition for prizes in the department in which they act as Stewards or officers."

— **CATTLE DISEASE IN LANCASHIRE.**—Information has been received by the Clerk of the Peace for Lancashire that cattle disease has broken out on a farm at Rawtenstall. Three of the affected animals have been slaughtered by order of the Inspector. The remainder of the herd consists of twenty-three cows. The Inspector states that every effort is being made to stamp out the contagion. The Bacup Inspector reports a further outbreak of disease among swine. The affected animals are promptly slaughtered.

— **HOPS IN ENGLAND AND AMERICA.**—The crops in Kent are extremely variable. Side by side are good and bad grounds. Some expected in a few cases to yield nearly a ton an acre; others, despite timely sulphuring, hardly worth picking at all. The "red mould" has been very mischievous around Maidstone; and Mr. Roger Leigh, the Member for Rochester, is said to have decided against picking his Hops at all, as they are so bad that he could only do so at a loss. Still the Hop crop is immeasurably better than that of last year, when the largest cultivator in this part of Kent had only three hundred pockets instead of the three thousand his gardens produce in a fairly good season. The Hop crop in the State of New York and throughout the country this year will exceed that of last year 25 per cent., or about 150,000 bales. In New York City a few days ago new Hops, grown in Oneida county, brought 50 cents per pound.

— **THE HARVEST AND GRAIN VALUES.**—The crops are secured in the southern counties, and nearly secured in the midland, while in the north great progress has been made in this important work. With a continuation of the fine harvesting weather and another large arrival of foreign Wheat the quotations of all descriptions again gave way at Mark Lane on Monday—English 2s. per quarter, and foreign 1s. to 2s. per quarter since last week. Barley, Beans, and Peas unchanged; Maize quiet, and unaltered in value. The supply of foreign Oats was again large, being 105,000 qrs. for the week. The low prices attracted buyers, and the bulk was cleared off, good corn selling in most cases at an advance of 3d. per qr. over the rates current on the previous week.

— **FRENCH WINE HARVEST.**—The splendid weather which has now prevailed for several weeks is having the happiest effects on the prospects of the vineyards, and it is expected that the yield will be above the average in the Charente and a portion of Gironde, and moreover of excellent quality. Not only has the phylloxera mani-

festated no fresh energy, but many of the Vines seem to be recovering, which is partly attributed to the excessive severity of the last winter. In the Midi and Burgundy districts the Vine crops look exceedingly well; and in Champagne also the quality is excellent, though the quantity is rather deficient.—(*Times*.)

— **THE BUTTER GRAIN AND BUTTER MAKING.**—The dairyman, says a correspondent of the *Prairie Farmer*, cannot be too careful in selecting his cows. The cream from one poor cow mixed with cream from fifteen or twenty good animals will injure the butter. Different opinions have been given about the grain of butter, and there are different modes of making butter. The old process of making it was to gather it into a body, then press out the buttermilk and work in the salt. The new method of making butter is to remove all the buttermilk as soon as the grains are formed, then work the salt and grains together, warm it, so it will press into a body, and it is ready for market. The old process is like mashing up ripe Strawberries to remove the hull; the new, like carefully removing the hull and leaving the berry whole and round. If the butter is made too warm while churning and finishing it an inferior article is the result. The contents of the churn should be kept between 53° and 60° to finish butter by the granulating process.

— **BREEDING FINE TURKEYS.**—We have seen it stated that Mr. Lythall prefers to breed from gobblers not exceeding two years old, and his example has been quoted as if conclusive in favour of this course. It will have been noticed, however, that the cockerel which is certainly the heaviest yet bred in England was bred from Mr. Simpson's *old* bird; and as the Americans have hitherto beaten us in weights, this agreement with their theory is pretty nearly conclusive, besides being borne out by the almost unanimous opinion of English breeders. The great objection to using old gobblers lies in their weight; but a way to remedy this has already been pointed out, and removes the difficulty entirely. Mr. William W. Clift, another celebrated American Turkey breeder, and formerly editor of the *American Agriculturist*, in an article upon breeding Turkeys in the *American Poultry World*, is equally strong upon the necessity of using fine matured males. "In rearing this or any other variety," he says, "almost everything depends upon the parent birds; yet in nothing are farmers more careless. The common practice is to sell off the heaviest birds at Thanksgiving and Christmas, and take the late birds of light weight for breeding. The excuse for this is that the heavy cocks wear the feathers from the hen's back, and the heavy hens are more apt to break the eggs in the nest. But these notions are old wives' fables that ought to be banished from the poultry yard. Another objectionable practice is to breed only from yearling hens. The old birds are generally sold off because they have four or five more pounds of flesh upon them. The Turkey does not attain its maturity until the third year, and the largest strongest chicks can only be secured from mature parents. So common is the practice of selling off everything at a year old or less, that it is almost impossible to get stock two and three years old. In purchasing breeders, it is the best economy to buy the heaviest birds, even at fancy prices. A ten-months cock weighing thirty pounds is cheaper at fifty dollars than a twenty-pound bird at five. Young hens weighing sixteen to eighteen pounds are cheaper at twenty dollars than twelve-pound birds at five. Large, well-formed birds, of perfect plumage, will leave their mark upon their progeny."—(From "*The Illustrated Book of Poultry*" for June.)

NEW AND OLD PRACTICES OF BEE-KEEPING.

No. 1.

"BEE-KEEPING is making such rapid progress now that stereotyped men and notions will soon be left far behind." "Modern improvements in hives and management with their enlightened advocacy are doing much to remove prejudice, dispel ignorance, and introduce a system of bee-keeping both humane and profitable." Such statements as the above are common, and honestly made by earnest and enthusiastic men. They mean well. Would that I could endorse all that they say. Who does not see that an exaggerated import is given to almost every novelty and invention of home and foreign growth? About ten days ago a clever bee-keeper came here to tell me his experience during the present season. He keeps about eight stocks, and originally belonged to

the old school of large straw hives, and was successful beyond his neighbours. Last year he adopted new ideas, and bought some bar-frame stocks and hives, and some comb foundations. In every trial this year with artificial foundations he failed, and succeeded beyond expectation with natural comb. "Indeed," he said, "I am taking all the combs out of the bar-frame hives and fixing them in straw hives." "How can you do that?" he was asked. "I cut off with a sharp knife all the cells of the old combs down to their foundations; and thus pared down to their foundations they are fitted into the straw hives, and the bees adopt them at once and erect new cells in the places of the old cells." "But surely you do not use such old foundations in supering." "Oh no, only for brood comb, and it answers first-rate." This is novel enough, certainly, and if found by experiment to be of much value will go a long way to prove that new artificial foundations will become of considerable importance in apiculture. Might not the British Bee-keepers' Association render important service to apiculture by seeking and publishing evidence for and against new and old practices in bee-keeping?

Has the world been enriched at all by the discovery of the old lady in the Highlands of Scotland? She found that bees eat barley bannocks soaked in honey, and others followed her practice by feeding their bees with pea-meal cakes and candy cakes made of meal, sugar, and water, believing the meal or flour in the cakes caused the queens of hives to commence laying earlier in spring, and also recommence laying in autumn after the breeding season had passed. This idea of meal food was widely published at the time, and many bee-keepers resolved to try the food by way of experiment. Have any or many of the readers of this Journal found meal food of advantage to bees? In my apiary I have tried this food for two or three years without any apparent advantage whatever. Long before one writer had recommended pea-meal dough to be plastered on the combs of hives in spring, and predicted advantages from it, I had tried it by putting the meal on combs and placing them on the boards inside the hives. I found the bees taking part of the meal dough, but I could not discover any advantage derived from so doing. The bees that did not have meal food either inside or outside their hives were just as healthy and prosperous and swarmed as early as those that had meal. Though bees in spring readily work on pea-meal and flour, and carry a large quantity into their hives, we have made no accurate experiments with them in order to estimate their proper value to the bees, or how they are used. Evidently most pollen and meal are required when breeding is going on in hives, and as evidently far too much is carried into some hives, for we often find one-third of the cells in the centre of hives half filled and thus rendered useless by pollen and meal. Bees in hives with little pollen in them thrive faster, other things being equal.

That the adult bees themselves eat pollen was well asserted and supported by Mr. Raitt some two years ago. In the excrements of bees he found portions of pollen grains, and also that the colour of the meal or pollen eaten determined the colour of the excrements. Nothing, it appears to me, could be more convincing than this evidence. How much or how little pollen is eaten by adult bees is a question yet unsettled. Mr. Raitt stated at the same time that the bees on eating meal overfed their queens with half-digested food from their own stomachs, and thus caused the queen to lay eggs at an untimely season. This was a new idea and an extraordinary one. Doubtless Mr. Raitt meant abundant feeding instead of over-feeding, for over-feeding would do harm instead of good; but this question of over or abundant feeding of queens cannot be proven, and therefore we need not dwell on it. Queens are seldom straitened for want of food—either honey or pollen—even when their subjects are threatened with starvation. Bees in inclement weather or when they anticipate hard times almost invariably stop breeding, the combs become empty, prosperity is checked. Does this happen from want of food or want of eggs? My opinion is that the queen being well fed cannot stop laying eggs in the egg season, but the bees will not hatch them. Ample evidence of this may be noticed in both large and small apiaries when feeding is resorted to during severe weather. Bees artificially fed during the worst weather in spring, summer, and autumn never cease to set and hatch eggs, whilst the hives when the bees are unfed become empty of brood. The administration of common artificial food—viz., sugar and water, promotes heat and contentment and brood-rearing in all hives without the admixture of meal. During the late hot weather bees in this locality did not gather honey enough to keep them, and the brood-rearing naturally came to an end about the beginning of August; but the bees artificially fed have continued to rear brood through August, and eggs are being set now during this first week of September. The question of the unfertility of bees

during inclement summer weather is a most interesting and important one. It will be well if the bee-keeping readers of this Journal succeed by artificial treatment in getting a large hatch of brood in every hive during the present month.—A. PETTIGREW.

OUR LETTER BOX.

Ducks Losing Feathers (E. T. E.).—They are too nourishingly fed. Give them soft food only, equal portions of barley meal and bran.

Converting Stocks in Skeps into Stocks in Frame Hives (J. B.).—The work of converting your apiary into one of frame hives had better be undertaken now. Any large skep which has a good population may be made into a moveable comb stock, but if the populations are thin it will be better to unite two into one at the time you take the honey. In the latter case gradually bring the stocks side by side, moving each about a yard daily, and then drive both lots into one skep. Cut out the honeycombs, and appropriate all that it is profitable to take, fixing the brood into the frames of the new hive by tapes. If you have not comb enough to completely furnish the frames give if possible foundation in the empty ones. Put your combs and frames in order, and then add the driven bees. Feed them until they are amply supplied for the winter. By this plan you save all your bees and brood, the latter being of great value, as it will furnish the bees that will survive till far into next spring. Your honey also will be secured as completely as you like to take it, while sugar becomes its perfectly sufficient substitute.

Hives (Idem).—The Cheshire hive can be had of Messrs. Neighbour, Regent Street. Mr. Green, Rainham, Kent, would be able to supply you with the description of hive to which your latter question applies. Look into any good modern handbook, and read "Uniting" and "Transferring," and consult it and our advertising columns.

REMARKS.

29th.—Fine, bright, pleasant day; distant thunderstorms in evening and night.
30th.—Fine and bright early, cloudy day.

31st.—Fine pleasant day.

1st.—Fog in early morning, fine bright day.

2nd.—Fine, bright, hot day, scarcely a breath of wind.

3rd.—Fine, bright, and very hot.

4th.—Fine and bright, the hottest day this year.

The weather during the week was fine and bright with a continued absence of rain; the temperature was high, especially during the last few days, and all the thermometric means are above those of last week with the exception of the minimum on grass. The barometer readings were also high.—G. J. SYMONS.

COVENT GARDEN MARKET.—SEPTEMBER 8.

We have little to note this week, large supplies of Channel Island Grapes and French Pears reaching us, the latter realising good prices. Kent Cobs and Filberts are short at increased value.

VEGETABLES IN 1880.—No. 1.

POTATOES AND PEAS.

WITH the exception of many Potatoes being diseased, I hear from various quarters that this is one of the best seasons for vegetables which has been experienced for a considerable time. Potatoes, however, are very much diseased, which is greatly to be regretted, as there are many vegetables we could better afford to lose than this most valuable crop. Now that the Government Committee have failed to find us either a prevention or cure for the Potato disease, and all prescriptions have proved of little or no benefit, the matter must rest with gardeners and farmers to try and find out which are the best varieties to resist the disease in the various climates, soils, and situations, and then to grow these alone. Very much might be done in this way, as no one will have grown a few dozen sorts of Potatoes without soon proving that some are very liable to the disease, while others resist it to a greater or less extent under the same circumstances.

Last year I cultivated over seventy varieties of Potatoes in the garden. Some were so much diseased that they became quite extinct, others nearly so, while some were hardly affected, and a few not at all. Thinking that last season was one of the worst ever experienced for trying Potatoes, I resolved to give all the varieties of which I had seed left another chance this year. This has not been carried on under the most favourable circumstances, as the persistent rain we had in July was much in favour of the disease, but now when lifting the crops I find with one or two exceptions that the condition of each variety corresponds very closely with the results of last year. Those which best resisted the disease last year have done so this, and the varieties badly affected then are the same now. Had I been satisfied with the result of the trial last year, and only grown the disease-resisting varieties in 1880, we might have had fine crops of Potatoes nearly or quite exempt from disease; but the experience of this season has enabled me to make a more reliable selection for future cultivation than I could have done before. Practice of this kind would, I think, lead many to obtain sound crops, and as we are now in the midst of the Potato-lifting season I advise all interested in the matter to give the subject their consideration.

Varieties which are half lost and the tubers left of doubtful condition should not be stored near a sound variety. The latter should be kept by themselves; and instead of using the best or greater part of them for cooking purposes, let the whole

of them be saved for seed, and eat the varieties which have partly succumbed to the disease.

All gardeners, indeed every possessor of a garden, has always a hankering after "variety." Growing a great number of varieties is commendable if done with the object of making a "selection," but further than this the plan should not be carried. Growing, say, fifty varieties of Potatoes may be interesting cultural exercise, but if more than the half of them are annually lost through disease it would certainly be wiser to adhere only to those varieties, no matter how few they may be, that experience proves are the most to be relied on for securing sound crops.

Respecting my selection, it will not include more than six or eight varieties, and these will be Rivers' Royal Ashleaf and the Gloucestershire Kidney for early work; and Scotch Champion, Magnum Bonum, Schoolmaster, Porter's Excelsior, and Improved Peach Blow for autumn and winter. These are the cream of the seventy varieties, being almost or entirely free from disease. Magnum Bonum has resisted the disease wonderfully this season. It has a better constitution than any Potato grown. The stems grow to a height of 4, 5, and 6 feet, and they are about as hard and tough as a piece of Filbert wood. Improved Peach Blow has done admirably well with us. It is pink and white in colour, round, rather deep in the eye, of good average size, and very prolific. Some of our single sets have produced forty fine tubers, and not a diseased one amongst them.

PEAS.

These have been very satisfactory this season. A favourable spring brought the early varieties in well, and the mid-season Peas were all that could be desired. During August the dry weather was slightly against later varieties, but prospects are favourable for a late supply. Mildew affected some of the rows to a certain extent. This I attribute to insufficient moisture at the roots, because, although all the seed was placed in the ground singly some inches apart, the top growth was so robust and became such a mass that the rain was not able to reach the roots, and artificial watering was not always convenient. Of all ways of growing Peas there is nothing to surpass a good length of row with the plants growing a few inches apart. This increases the produce in quantity as well as quality. Growing them in trenches is a good plan in dry weather, or where the soil is very light; but in heavy soil the practice is unnecessary. I have tried some dozens of varieties of Peas from many different sources, but have eliminated gradually and carefully until I have only a few of the best and most distinct.

William I. has until this season been the earliest Pea grown, but it is surpassed in this respect now by a new variety we had on trial from Messrs. James Carter & Co., the eminent seed firm, and I might say the eminent Pea firm of London. This new variety was the first of all, and attained a height of 2 feet. The pods are smaller than those of William I., but they are more abundant, are ready for gathering quite two weeks earlier, and the peas are of equally good flavour. As early Peas are so much appreciated by all, these facts will no doubt soon be corroborated by other cultivators, and this variety will take the place it merits.

As rather tall-growing, second-early, midseason, and even late varieties, Telegraph and Telephone are most valuable. For growing freely, cropping abundantly, and producing peas of

high flavour they are now well known and justly appreciated. Amongst dwarf varieties the Challengers, Invincibles, Non-suches, and others of equal pretensions must all give way to Stratagem. This variety of rare excellency grows about 3 feet high. The stems are so strong that they will almost stand upright without any support. The pods are produced most freely in pairs from bottom to top. They fill quickly and well, each pod containing from nine to eleven large peas. Small pods here and there, or just a few large peas in the middle of the pod and both ends empty, as is the habit of fruiting of some Peas we could name, are failings unknown to Stratagem. It is ten days or so later than Telephone in coming into fruit, and, as a dwarf Pea, it continues bearing and supplying a succession of its splendid pods for a remarkably long time to be a dwarf Pea. In changeable seasons the weather sometimes affects varieties differently; and in case anything should happen to any of the varieties recommended, a row or two of Omega, which is a fine late Pea, may be grown to fill up the gap.

Wrinkled Pea seed did not germinate so well last spring as the round, but all varieties should be thoroughly well ripened this year, and we may look forward to having good Peas in 1881.—J. Muir, *Margam*.

DUTCH BULBS.

THESE have again come to hand, and it is pleasing to find that they are generally larger than has been the case for the last year or two. For securing good bulbs and satisfactory results it is very necessary for buyers to be early in the market. I do not know whether the earliest purchasers obtain the best goods, but I presume they do and act accordingly, whilst I also like to have the bulbs early so as to place them thinly in a cool room, where they move slowly under my own eye. Another reason for having the stock early is the necessity of potting the first batch early in the autumn. Another point which is worthy of impressing on those who have only a limited knowledge of the different varieties is this, that the number of varieties really worth growing is comparatively limited, and it is therefore better, when the quantity grown is more or less large rather to increase the number of bulbs of one variety than to add to the number of varieties. As a rule it is possible to purchase the bulbs cheaper by the half-dozen, dozen, or hundred, than it is to purchase them one or two of the different varieties. Suppose a batch is required to bloom early in the year, we have amongst Hyacinths Charles Dickens, blue; Homerus, red; Crown Princess, white; and Norma, blush. The earliest Tulips are Due Van Thol, red and yellow; Due Van Thol, crimson; Canary Bird, yellow; and the common double Due Van Thol. Polyanthus Narcissus are represented by Paper White and Double Roman. These with Lily of the Valley and some late Roman Hyacinths give a good and cheap display till February. From that date there is no difficulty in most gardens to insure a more varied display.

Some of the best and easiest to manage are in Hyacinths Charles Dickens, Marie, King of the Blues, Mimosa, and Grand Lilas amongst blue shades; Von Schiller, Macanlay, Fabiola, Gigantea, Koh-i-noor, and Lord Wellington (double) amongst the shades of rose and red. Useful whites are Alba superbissima, Grandeur à Merveille, Mont Blanc, and La Tour d'Anvergne (double). Ida and Heroine are good yellows; and Haydn is an excellent mauve.

Good and cheap Tulips are Chrysolora, Cottage Maid, Keizerskroon, Pottebakker, Rose Gris de Lin, Proserpine, Wonverman, and Joost Van Vondel amongst singles. I only grow one double variety—Imperator rubrum. Amongst Polyanthus Narcissuses Gloriosa, Grand Soleil d'Or, and Grand Monarque are very reliable. A quantity of Crocuses grown in pots to cease flowering just before those in the borders bloom are very attractive. The following have blooms as large as many Tulips—Albion, Caroline Chisholm, Correggio, Grande Vidette, Madame Mina, Lord Palmerston, Havelock, Sir Walter Scott, Cloth of Silver, and the largest yellow. Other bulbs which should be grown are Seilla præcox, Tritelia unicolora, Iris persica, and Iris reticulata. The earlier-blooming Trumpet Narcissi are also very attractive grown in pots. N. Bulboodium and N. Horsfieldi should certainly be grown.

Many may think that the list of varieties above given is rather restricted, but I do not find it so; and those who have an opportunity of exhibiting in spring will find it possible to select good exhibition plants from amongst the varieties named. I am not, however, writing for exhibitors, but for amateurs and gardeners who desire to render their houses gay as inexpensively as possible.

As to cultivation, the main object is to extract as much as

possible out of the bulbs, it being well known that very much depends on the growth made in Holland the previous year for the quality of the display in spring. We take every care of the bulbs after reaching us to keep them cool and free from excitement, so that a long rest may be ensured, and that as little loss as possible may be felt by the bulbs during this resting process. When they show signs of growing, as when roots are discernible and young growth is noticed from the centre of the bulb, then it is time to pot. Throughout winter coolness and darkness are very necessary, and until the young growths have been inured to light after removal from the plunging material coolness is very essential. After that heat is given according to the time the plants are wanted in bloom, though it is well to bear in mind that much better spikes and flowers are secured in a moderate temperature. Nor do the flowers last so long when they have expanded in heat. The amount of water required will also have to be regulated by the degree of heat given. When the plants are kept rather cool much water will cause the quill-like roots to decay, while a higher temperature will cause these same roots to appropriate much water. The soil must be very open, the addition of coarse sand to the compost being very necessary. A fourth part of old Mushroom bed material, or dry cow manure rubbed down fine, should also be incorporated with the loam for all Dutch bulbs. The size of pots must be to a great extent determined by the requirements of the place. Most of our Hyacinths are potted singly and grown in 5-inch pots. Many of the Tulips are grown three to five in pots of same size, Crocuses and Seillas eight, and Double Roman, Paper White, and Gloriosa Narcissus three in pots of the size named. We also grow Hyacinths two, three, and six bulbs in a pot, Tulips and Polyanthus Narcissus more or less after the same manner according to size of pots employed, those 8 inches in diameter being the largest used. As to dates for potting—our Roman Hyacinths have been potted for some time, and the earliest Tulips, Hyacinths, and Narcissuses will be potted this week, the main quantity of bulbs being potted in October.

Perhaps a word or two would be useful to cultivators of Hyacinths in glasses. All the varieties above named are suitable for that purpose. I place the bulbs in glasses at the same time the main lot are potted, the water being kept just a little below the bulbs. Clean soft water only is used. The glasses are placed in a cupboard in a bedroom kept generally quite cold, and there they remain until about the same time the others are taken out from amongst the plunging material, say the middle of January at latest. They can be brought on rapidly or slowly, according to the temperature of the room in which they are placed.—R. P. B.

THE PLAGUE OF WASPS.

A PLAGUE of wasps this summer is no myth; the air is full of them. For every ten that are killed twenty wasps are at hand to rush into their places. The hordes which are at this moment devouring all our fruits are, in their own field of operations, scarcely to be outdone in the completeness of their destructiveness even by the locusts. Such is our experience on the southern hill slopes of Surrey.

How it happens that after an exceptionally wet and sunless summer and autumn, followed by a long and frosty winter, there are found to be this season more wasps than the memory of living man can parallel, is a matter well worth inquiry. So also slugs, which are said to perish during hard frost, have been most numerous here this year; whilst bullfinches in the spring, and blackbirds and thrushes, as well as other smaller birds in the summer, have been unusually destructive in this neighbourhood. There are clearly many things of everyday occurrence of which we know but little, and about which we should certainly become wiser if we would patiently observe and record facts before we express merely opinions.

Reverting to the wasps. They come as soon as the air is warmed by the sun, and whatever fruit is showing the first signs of ripening, upon it they alight. One or more commence operations by eating an aperture in the skin, and a cavity is soon formed, into which enter as many of the greedy marauders as the hole will contain, and soon nothing is left but the skin and the stone. They appear to eat and drink to repletion; for when shaken from the hole in the fruit they fall heavily to the ground, and seem to be incapable for some moments to rise, so that they can be easily crushed beneath the feet. They work rapidly. A tree of Reine Claude de Bavay Plum in an orchard house bearing a fine crop of fruit fit to gather was safe at 10 A.M., but at 2 P.M. half the crop was utterly destroyed by wasps. Some of the creatures even at night do not go home, but linger on the scene of their depredations, whilst some abide within the fruit which they have excavated. There is an opinion in these parts that

wasps retire to their nests at noon daily. I cannot say that I have observed this to be the case.

What can be done to mitigate the effects of this plague? The nests if found can be destroyed. One neighbour has had over a hundred nests in his grounds thus treated, others eighty, and so on. The wasps in many of these nests have been killed most easily by introducing just within the nest a piece of cloth fastened to a stick, soaked in a saturated watery solution of cyanide of potassium. The effect is, I understand, immediate death to all within the nest. The cyanide, I ought to mention, is a powerful poison, and care should be taken in its use not to breathe the emanations from its solution. Many nests have been destroyed on our own grounds. Those which were approached by a descending channel were drowned and scalded by pouring a good quantity of boiling water upon them; others on a bank, which seemed to have an ascending covered approach, were easily filled with the destructive vapour of sulphurous acid—*i.e.*, the fumes from burning sulphur at the mouth of the nest. This latter is an easy and effectual method. One nest so destroyed when dug out was found to contain sufficient comb to fill a large-sized ordinary zinc pail. All our destructive operations were carried on in the dark, for most of the wasps are then at home, and a paraffin lamp, as well as pieces of rag soaked in paraffin, were kept burning near at hand. In this way the operators were protected during the process of destruction, for the wasps fly to the flame and many are thus killed.

But numerous nests are never discovered, and as each nest may contain so many as thirty thousand wasps, the hosts in such a season as this are diminished by all our destructive agencies in no very appreciable degree. Indeed, there is no reason to think that they often travel long distances in quest of fruit. Whether one wasp can communicate to another where these alluring treasures may be found, or whether some subtle emanation from the fruit is capable of impressing from afar the organs of some special sense apart from sight and perhaps smell possessed by the wasps, has yet to be discovered. Certain it is that after destroying every nest within our ken or reach, and killing in other ways seldom less than a quart of wasps daily, bands of robbers settle still upon every Apple, Plum, Fig, Grape, Peach or other fruit that is left to us and is approaching maturity. It is all the same whether within or without the glass houses, for the wasp hovering over the whole surface of the structures finds out some minute chink or hole, and there he enters.

All that we can do is to gather some of the fruit before it is ripe, and to cover some of the trees or the best laden branches with Haythorn's netting; in this way a remnant of fruit is vouchsafed to us. Some of the Peach trees we thus enclose; and as regards bunches of Grapes, if a bag of netting deprives the Grapes of their attractive bloom it does not interfere with the flavour.

By the way, I have observed in our vinery that the wasp assails the purple Grape first, and neglects the white Grape close by its side although equally ripe; thus, the fruit of two Vines of Trent-ham Black are eaten up, whilst that of Foster's Seedling is so far untouched. So also Madresfield Court is attacked, whilst Dr. Hogg remains unscathed by its side. May the great merits and virtues of Dr. Hogg be always thus protected from hostile attack!

One cannot practise the wholesale destruction of wasps without a feeling of regret that it should be necessary to sacrifice a people showing so much of ingenuity, industry, and untiring energy. Even although they be bold and unscrupulous thieves, they are entitled in justice to have their fair side also recognised. I have this day seen numbers of them busy on the leaves of a Plum tree infested by black aphids. Perhaps they had taken to this somewhat coarse animal food when thwarted in their banquet upon the luscious vegetable diet.—A SURREY PHYSICIAN.

[Our esteemed correspondent's article was written before the publication of Mr. Taylor's notes on page 240, which we think show at least one great cause of the abundance of wasps this year—namely, a "dry spring, and especially a dry May." Destroying the queens at that season—and all wasps are queens then—is the true mode of preventing the plague that is this year so destructive.—EDS.]

LOBELIA "WHAT'S THAT."—Amongst other plants tried this year we have a Lobelia from Swanley with the above absurd name. Just fancy taking a walk round the garden with a friend, who stops at a plant he never saw before, and queries, "What's that?" and you answer "Yes!" Until the middle of August our new friend with the funny name did not at all attract my attention, but since then I have been gradually taking to it, and next year, all being well, it will be grown in quantity. Its peculiar charm is in the shade of colour, though it also flowers profusely.

With the sun shining on the plants it presents a silvery appearance, though the colour is of the faintest lilac. Lobelia Dixon's Gem is a great improvement on Lady Macdonald. There are also two new Ageratums from Swanley well worth growing.—R. P. B.

PRUNING FRUIT TREES.

THE extreme difference of the weather this autumn from that of the last three years, which were as unsuitable for ripening all kinds of fruit trees as could well be imagined, gives every hope of next season crops being full. To make the most of the weather it is, however, necessary that we should bestir ourselves and give our trees every opportunity of profiting to the utmost from the glorious change we are now experiencing. In my own case, as I found that Pears and some others would be all but failures this season, I early in the summer thinned-out spurs and extra wood, so that these have had the whole summer and autumn to develop strong buds. Apricots, Plums, Apples, and other fruits are now being pruned so as to give them every benefit of the warm air.—R. B.

MORE ABOUT POTATOES.

WE have been blessed with a marvellously prosperous season here in Devonshire. The weather from the end of April to the present time has been simply perfect. Other parts of our islands have suffered from destructive thunderstorms accompanied by hail and heavy rains, but they have happily not passed over this neighbourhood. Occasionally a refreshing shower has fallen, so that we have not experienced anything like a drought, and yet there has not been sufficient rain to hurt those crops which are impatient of excessive moisture. A most bountiful harvest has been gathered-in in the best possible condition, while the Potato crop is one of the finest on record. We have, therefore, every reason to be thankful. For Potato growers especially it is most cheering, for it appears as though a panic was rapidly setting in among them. A succession of bad seasons had driven most of us to our wits' end to know what to do next. The cry of "Something must be done" was loud and frequent, but the doctors as usual disagreed. All kinds of remedies for the disease were suggested, but all alike failed to stand the test in the hour of need. Science has stepped in, and with the aid of the microscope has enabled us to see and to take the measurement of the little fungus which is at the bottom of all the mischief, but as yet no microscope has been found powerful enough to bring to view the antidote. Now for my part, although I admit that it is a good thing to be able to see your enemies, it is better still to see the means of defeating them. Many profess to tell us how to do so. One cries "Plant deep;" another, "Plant on the surface;" another, "Pull up your stalks;" another, "Leave them on;" another, "Lift while the haulm is green;" another, "Leave the tubers in the ground until the disease has done its worst." These are but a few specimens of a multitude of contradictory directions given by cultivators who have all, it appears, carefully conducted experiments and arrived at different conclusions. This proves decidedly that as yet no real remedy has been discovered.

Disease-resisting Potatoes, so called, are another panic makeshift, the outcome of a series of bad seasons; to be tolerated indeed, but only at such times, seeing that this tendency to resist disease (and it is only a tendency at the best) is generally their only recommendation. Coarse in stalk and root, gross feeders, cakes of soap rather than balls of flour, the majority of them are fit only to be cast out to feed the pigs. Like "A LINCOLNSHIRE POTATO GROWER," I also would enter a protest against the introduction of such varieties as a step in the wrong direction. I am not one who thinks that a bad Potato is better than none at all. With the great variety of farinaceous foods which are now obtainable at a cheap rate, the poorest person need never be reduced so low as to be compelled to eat those waxy indigestible lumps which pass for Potatoes fit for human consumption in these days. Moreover, I do not despair of a good time coming, perhaps not so very far distant, when the disease cycle shall have rolled away, and the Potato plant shall again be as free from its present adverse circumstances as it was in times past.

When that happy time comes what a misfortune it would be for us or our posterity to have nothing left in our hands but coarse and inferior varieties. And yet such a calamity is by no means improbable if the present neglect of the finest and most delicate kinds is persisted in for the sake of those varieties which are more sure to produce a paying crop, by reason of greater staying qualities. Unfortunately this power to stay seems to be linked inseparably with inferior qualities in other respects. And you may be quite sure that if a Potato has any claims to be a resister of disease, it has few to be either palatable or presentable at table.

Moreover, all those varieties raised so far are sorts which ripen late and occupy the land for at least six months of the year. This of itself is a serious disadvantage. It appears to me that what we want is to get rid of all those rank-growing coarse late Potatoes, and to substitute for them something of the Early Snowflake type. I can cordially endorse most of the statements made by "LINCOLNSHIRE POTATO GROWER" in his sensible and interesting paper, but must demur to his opinion that a Dwarf Champion or Magnum Bonum would be a desirable addition. I think the aim is not high enough. What is really needed is a Potato of good flavour, white, floury, and shallow-eyed; short-haulmed, ripening early, standing wet well, cropping well, and keeping well. Try for this, raisers, and when you get it have the kindness to send me a bushel to try. Perhaps if you, Messrs. Editors, will yet have patience with me I may mention a few kinds which do well here on some future occasion. The Journal is just to hand. In it I notice "W. B. W.'s" explanatory comments. His practice is excellent, all that I objected to was the use of the largest sets for seed when smaller sets, in my experience, produce equal or better results with a smaller outlay.—R. W. BEACHEY.

TROPÆOLUM SPECIOSUM.

THE following observations upon this lovely trailer may be interesting to some of your readers. The plant alluded to in this Journal (pages 212 and 230) is in moist sandy soil, to which peat and leaf soil have been added. The large-leaved Aristolochia is growing close to it, amongst which it twines its slender branches; the roots run into the brick wall and are otherwise completely protected and shaded from the sun by herbaceous plants, such as *Anemone japonica*, &c.

I have tried in vain to grow the *Tropæolum* from roots and potted plants brought from Scotland, all of which have failed in the manner described by "M. M." Three years since a lady residing in Wales kindly sent me some roots from her garden; these grew without a check, flowering last year, and are this year growing and flowering vigorously.—E. E. P., *Richmond*.

TROPÆOLUM SPECIOSUM grows well in Cornwall in a Rhododendron bed in a deep peat soil. It has long fleshy roots, which are found nearly 2 feet under the ground. It grows also on a west wall sheltered by trees, scrambling amongst a Banksian Rose, where the soil is principally composed of decayed leaves covered with rockwork, which keeps the roots cool. It must have deep soil, and its roots protected from drought. When growing it delights in copious supplies of water.—M. G. H.

BRIGHTON HORTICULTURAL SOCIETY.

THE autumn Exhibition of this Society was held in the Royal Pavilion on Wednesday and Thursday the 8th and 9th inst., proving in number and quality of the exhibits fully equal to the many fine displays that have been produced during the past twenty-seven seasons of the Society's existence. The schedule enumerated over seventy classes in two sections, one comprising classes open to growers from any part of England, and the other those confined to growers in the county of Sussex. In the most important classes liberal prizes were offered, and in consequence the competition was in many instances very keen and the entries numerous. Plants generally were well represented, though flowering specimens were not quite so strongly shown as those which came under the denomination "fine-foliage plants." Cut flowers constituted a bright and important feature in the display, while fruit was equally good and abundant, several exceptionally fine collections being staged. The majority of the large specimen plants occupied a long and spacious marquee, in which were also placed such plants as *Pelargoniums*, *Fuchsias*, and *Coleuses*, with the cut flower classes provided for *Dahlias*, *Asters*, and *Roses*. The central portion of the marquee contained the specimen fine-foliage plants in a line or bank extending from end to end. Near each side of the marquee was a row of well-flowered *Pelargoniums* that collectively produced a brilliant effect; between these on each side of the central bed were the stages devoted to cut flowers, and at the ends near the entrances were groups of *Fuchsias* and *Coleuses*. In the handsome apartments of the Pavilion itself were arranged the groups of miscellaneous plants, the specimen stove and greenhouse plants, the table decorations, bouquets and fruit. There was sufficient colour to produce a good display, which was, however, much more brilliant at night when the apartments were lighted with gas, for then the rich green tints of the foliage, the brightly coloured flowers of such plants as *Bougainvilleas*, *Allamandas*, and *Rondeletias*, combined with the ornate character of the surroundings, constituted a scene of great beauty. The whole of the arrangements were satisfactorily carried out under the superintendence of Mr. E. Spary of

The Queen's Graperies, Brighton, who has for many years performed his task very creditably.

Plants.—The most important open class for plants was that devoted to fine-foliage plants and Ferns, of which twelve specimens, distinct varieties, were required. Three prizes were offered, the first being the "Corporation cup," value ten guineas, presented by the Mayor and members of the Town Council, the second prize £4, and the third £2. Six competitors appeared, who staged admirable collections of healthy specimens, all very close in merit. The premier collection was that from J. Warren, Esq., Handcross Park, Crawley, Sussex (Mr. Rann), for which the cup was awarded. All the specimens were exceptionally fine, but the following were particularly noticeable not only for their size, but the vigorous healthfulness which marked them:—*Croton Hendersoni*, very handsome, about 5 feet in diameter, foliage large and well coloured; *Gleichenia Mendelli* and *G. rupestris glaucescens* were both large and in good condition; *Thrinax elegans*, fine graceful specimen over 10 feet high; *Pritchardia pacifica*, in first-rate condition, with enormous leaves; *Dasyllirion acrotrichum* and *Seaforthia elegans*, excellent, the latter of great size. Mr. W. Balchin, Hassocks Gate, Cliftonville, who has several times been the winner of the cup, was on this occasion placed second, the quality of Mr. Rann's plants being irresistible. The most noteworthy specimens were *Croton pictus*, of good size and well coloured; *C. Weismanni*, also finely coloured; *C. volutus* and *C. majesticus*, all in admirable health; but four *Crotons* in a collection of twelve were rather too many. *Cycas revolutus* and *Cibotium regale* were the best of the other specimens. The third position was obtained by Miss Brodie, Eastbourne (Mr. C. Driver), with good examples; and Mr. W. Miles, 39, Church Road, was awarded an extra prize for a deserving collection. *Coleuses* were shown in good form and colour by several exhibitors. For a collection of six specimens the Mayor of Brighton (gardener, Mr. Tringmar), was awarded the chief prize, the plants being remarkably fine in every respect. They were grown in a somewhat flat umbrella shape, over 5 feet in diameter, well covered with large richly coloured foliage. The varieties were Shrive's Seedling, Princess Louise, Golden Gem, William Bull, Sir Bartle Frere, and Jacob Mackoy. Mr. Shrive, gardener to the Corporation of Brighton, followed very closely, also with good specimens, more pyramidal in form than the others, but rather less brightly coloured. Magic, Glow, George Bunyard, and Shrive's Seedling were the best varieties. Zonal *Pelargoniums* were very bright, and in some collections remarkably well flowered. The chief successful exhibitors were A. Granville Uttermare, Esq., Withdeane (Mr. Howick); C. Armstrong, Esq., Withdeane (Mr. E. Meachin); Capt. Thompson, Withdeane (Mr. Townshend); and Messrs. Balchin and Miles; a collection of well-grown double-flowered Zonals from the former of the two last-mentioned being highly commended by the Judges in addition to taking the first prize in the class. *Fuchsias* were generally in fresh healthy condition but somewhat deficient in flowers, except the specimens staged by Mr. Howick; J. O. Smith, Esq., Richmond Villa (Mr. Fluck); and Mr. Shrive, for which the principal prizes were awarded. The stove and greenhouse plants which occupied the apartments of the Pavilion were very creditable and satisfactory, the *Allamandas* being particularly fine. Several neat *Stephanotis* and *Rondeletias* were also shown, but the others do not call for special comment. Messrs. Meachin, Driver, Balchin, Miles, Townshend, and T. S. Shenstone, Esq., Barcombe (Mr. Verrall), secured the most important prizes. Ferns were shown by Messrs. Driver and Meachin in admirable condition, the *Gleichenias* being especially noticeable for their freshness and vigour. The competitors were few in the open class for a group of plants arranged for effect to occupy a space not exceeding 150 square feet; but two very attractive and tastefully arranged collections were contributed, one, which secured for Mr. Balchin the first prize, being composed of a large number of effective and well-selected flowering plants elegantly combined with *Crotons*, *Dracenas*, Ferns, &c., and the other, also a meritorious group from Mr. Miles, who was placed second, contained some fine *Liliums* with *Ixoras*, Palms, *Crotons*, &c., neatly edged with *Isolepis gracilis* and *Adiantum cuneatum*.

Cut Flowers.—These constituted a very important feature in the display, and the general quality was all that could be desired. *Dahlias* were strongly represented in the four classes devoted to them. In the open class for forty-eight distinct show varieties three handsome collections were exhibited, the premier position being obtained by Messrs. Keynes & Co. of Salisbury, who staged some magnificent blooms, excellent in form, substance, and colour, and including an admirable selection of varieties. Mr. H. Cannell of Swanley, Kent, was accorded the second prize for a remarkably fine collection that was but slightly inferior to the first, the varieties being judiciously selected and tastefully arranged. Mr. W. Seale, Sevenoaks, Kent, followed with smaller but neat blooms. In the class for twenty-four fancy varieties the above-mentioned exhibitors obtained the prizes in precisely the same order, with very good representative blooms. The *Dahlias* in the county classes were also good, the successful exhibitors being Miss Melvil, Henfield (Mr. Allfrey); Mr. W. Steer, Pope Street; and Mr. Smith, Hedge Lane. Messrs. Keynes and Co. were the only exhibitors in the class for seedling *Dahlias* of 1879, four blooms of each. The chief prize was awarded for their collection, which included some handsome and distinct varieties, the following being honoured with first-class certificates:—Joseph Green, a beautiful and effective variety, the blooms of medium depth, good

full centre, and excellent in outline, the colour being a clear bright scarlet tint; Mr. Compton, a handsome flower of good depth and admirable form, high in the centre, of a rich deep purple hue; and James Vick, a flower of good substance and symmetry, the colour being an intense purplish maroon. All these are Show varieties. One Fancy variety, though not dignified with a certificate, deserves notice for its fine shape and colour—viz., Professor Fawcett, which had a ground colour of reddish purple streaked with maroon, the substance and symmetry of the blooms being first-rate. Cut Roses were numerous shown, and in fair condition for September. The most successful exhibitors in the open classes were Messrs. Mitchell and Son, Piltown, near Uckfield; Mr. W. Seale; Mr. H. Coppin, Shirley, near Croydon; Messrs. Bunyard & Co., Maidstone; and Mr. W. Balchin. Asters, Verbenas, and Marigolds were numerous and of good quality, the best being staged by the Rev. R. C. Hales, Woodmancote Rectory; Major Scott, Reigate (Mr. Morgan); Mr. H. Cannel; and Messrs. Verrall, Fowler, Stringer, Bevan, and Ward. For collections of stove and greenhouse blooms Mr. W. Balchin gained the chief awards with very bright and handsome specimens; Mr. C. Gilbert, Hastings, and G. S. Gibson, Esq., Saffron Walden, Essex (Mr. Archer), being second and third respectively. Table decorations, bouquets, and wreaths were well shown by Messrs. Miles; W. Brown, St. Mary's Grove, Richmond; S. Seale, Sevenoaks; W. Balchin; and F. Gallop, 30, Western Road, Brighton.

Fruit.—As is customary at the autumn Show of this Society fruit was remarkably well represented in point of numbers, and as regards quality the majority of the exhibits would have borne comparison with any staged at exhibitions this year. The chief interest of the display centred in the class for sixteen dishes of fruits, the first prize being a silver cup value ten guineas, presented by James Ashbury, Esq., M.P. for the borough. In this class there was no restriction as to the kinds of fruit to be exhibited, the term "dish" being defined as Grapes three bunches; Plums, twelve fruits; Peaches, Nectarines, Apples, Pears, or Figs, eight fruits—a very convenient distinction. There were only three exhibitors, although the second and third prizes were respectively £4 and £2, and the Show only of two-days duration; but many preferred entering the smaller classes. Earl Somers, Eastnor Castle, Ledbury (Mr. Coleman), was awarded the cup for a remarkably handsome collection including four varieties of Grapes—viz., Black Hamburgh; Trebbiano, the three bunches weighing 10½ lbs.; Alicante weighing 15 lbs.; and Muscat of Alexandria, all well ripened and finely coloured. Melons Old Egyptian and Golden Gem, both excellent; a good dish of Jefferson Plums; Grosse Mignonne and Bellegarde Peaches, large and well coloured; Elruge and Albert Victor Nectarines, fine; ripe brown Turkey Figs; superb Pitmaston Duchess Pears, and Belle de Bruxelles Apples, and two good Pine Apples. The Duke of Richmond, Goodwood, Chichester (Mr. F. Rutland), was second with fine examples of fruits well ripened. The best dishes were the following:—Black Alicante Grapes, fine and good colour; Royal George Peaches, Rivers' Orange Nectarine, Williams' Bon Chrétien Pears, Washington Plums, Brunswick Figs, and Pine Apples Charlotte Rothschild and Smooth Cayenne. The third position was accorded to Mr. Apted, Broadwater, for well-finished fruits comprising six varieties of Grapes rather small but well coloured, and handsome Bellegarde Peaches among others. Grapes were very fairly shown, six classes being devoted to them. For six bunches of Black Hamburghs Mr. W. Coleman was first with superb examples, large in bunch and berries, and grandly coloured. Mr. Knight followed with much smaller but fairly good bunches. For three bunches of the same variety Mr. Coleman was again to the front, followed by W. E. Hubbard, Esq., Horsham (Mr. Ford), and G. Duddell, Esq., Queen's Park (Mr. J. Spottiswoode), with creditable specimens. Mr. Coleman was first with three bunches of White Muscats, staging good examples of Muscat of Alexandria weighing collectively 11¾ lbs., but he failed to obtain a higher position than third with six bunches of the same variety, as they were somewhat green. For threes Mrs. Lambert, Bletchingley (Mr. C. J. Goldsmith), and S. Douglas, Esq., Tunbridge Wells (Mr. Bashford), were second and third. Mr. Spottiswoode staged the best six bunches in the corresponding class, Mr. C. J. Goldsmith following closely. All the other fruits for which classes were provided were also well represented both in the open section and those classes confined to the county, but it is not necessary to particularise them. The principal prizetakers in addition to those already mentioned were R. Bacon, Esq., Keymer (Mr. Hyde), The Right Hon. the Speaker of the House of Commons, Glynde (Mr. J. McLeod), R. Welland, Esq., Polgate (Mr. Cosham), F. B. Atkins, Esq., Halstead (Mr. A. Gibson), and R. A. Bevan, Esq., Cuckfield (Mr. Stringer).

Miscellaneous.—Numerous groups of plants added to the attractions of the Show, and one of the largest was that from Messrs. Veitch and Sons, Chelsea, which contained many new and choice plants of considerable beauty. Messrs. John Laing & Co., Forest Hill, London, staged a collection of Tuberous Begonia flowers. Messrs. J. Cheal and Son, Crawley, sent specimens of Cucumbers, Potatoes, and ornamental Gourds. Mr. S. Seale had a collection of Gladioli; and Messrs. Balchin and Miles also contributed largely.

The weather proved fine, and a great number of persons visited the Exhibition, especially in the afternoon and evening of each day.

APRICOT BRANCHES DYING—WASPS.—I have been examining our Apricot trees, and there is proof sufficient of what Mr. Cross-

ling says about the "borer" which he discovered in his trees. However, I am not prepared to assert that these insects are the sole cause of the branches dying off, yet the subject is worthy of more general attention than it has received. Almost as annoying as the dying-off of Apricot branches are the devastating hordes of wasps which have devoured everything before them. Our wasps go in for unripe as well as ripe fruits, and the only way to secure any fruit has been to gather it before the wasps had time to eat it up. We left the fruit on one Apricot tree, and to-day only five good fruits could be gathered. A neighbour arranged to gather his crop of Gooseberries one morning, but when the nets were removed the bushes were found to be like old Mother Hubbard's cupboard—bare. The only way to save crops is to cover them with hexagon nets. Attempting to trap the pests is merely playing with them. If next spring is dry and fine, and a large crop of fruit sets, it will be good economy to invest in a supply of hexagon netting. It lasts a great number of years with ordinary care.—R. P. B.

ACANTHUS LATIFOLIUS.

THIS handsome plant has been an object of considerable interest in my garden this year, both its leaves and flowers proving attractive in no ordinary degree. In the front of shrubbery borders and at the back of mixed flower borders the plants have

Fig. 52.—*Acanthus latifolius*.

an excellent effect, forming fine clumps, from which arise the tall flower stems bearing rosy lilac-coloured flowers. The leaves are large, rich deep green in colour, and remain in good condition until late in the autumn—a character of great value. Any moderately rich garden soil suits it, provided it is of good depth to allow the roots to roam at will. I heartily recommend all who have not grown it to give the plant a trial in some suitable position, and they will be well satisfied with the result. *Acanthus latifolius* has, I believe, been known as *A. lusitanicus*, but is regarded by some as merely a variety of *A. mollis*.—J. R.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

THIS Society's autumn Show was held on the 8th and 9th inst. in the Waverley Market, Edinburgh, the arrangement of tables, &c., being similar to former shows, the large central tables being furnished by the leading nursery firms, the other firms having tables for their produce in various portions of the hall. The plants for competition were more numerous than is generally the case, the average of quality being higher than usual. Fruit is one of the principal features at this Show, but there was a decided falling-off in

the quantity of all fruits with the exception of Grapes, while the quality was, with the exception of Peaches, below the average. A new feature, introduced for the first time this year, was the collections of Potatoes, no fewer than forty-one entries for the two collections being received. These, added to the large entries for other vegetables, made this portion of the Show a greater success than it has ever been, well as the vegetable classes are generally filled. Cut flower classes were the poorest, very few of the entries being up to the average.

The most noteworthy groups were the nurserymen's collections, the hardy ornamental shrubs arranged at the west end of the market by the Lawson Seed and Nursery Company; their central group of stove and greenhouse plants having a carpeting of small decorative plants arranged beneath tall *Dracaenas*, *Phormiums*, *Palms*, and *Lilies*, and the two groups of *Todea pellucida* and *T. superba* placed in two rows round a fine standard Sweet Bay. Messrs. Ireland and Thomson filled a large table with a group of plants by far the finest and most attractive in the Exhibition. The centre of their arrangement consisted of large *Palms*, Tree Ferns and specimen *Crotons*, large specimens of *Tuberous Begonias*, of which *Acme*, *Souvenir de Louis Van Houtte*, *Lucien Pencelle*, *Vesuvius*, *Brilliant*, and *Kallista* were amongst the finest varieties; *Crotons*, *Bertolonias*, *Dracaenas*, and other fine-foliaged plants were freely employed. On a smaller table the same firm staged some of the newest fine-foliaged plants. Particularly attractive were *Dracaena Smithii*, *Croton Archbaldi* with long drooping leaves and well coloured; *C. Warreni* with curiously twisted foliage; *C. Weismanni superba*, more yellow than the old form. *Phyllotenus Lindenii* and *Anthurium Veitchii* were also represented by large plants. Messrs. Downie & Laird had some large specimen *Palms*, *Lilies*, good plants of *Bouvardia Humboldtii corymbiflora*, *Rhododendron Duchess of Edinburgh*, and several stands of cut flowers. Of these the best were six dozen *Dahlias*, late *Phloxes*, and a grand collection of *Pentstemons*. They also staged a collection of bedding *Violas* and *Pansies*. On the next table Messrs. Methven had a large group of fine-foliaged plants, chiefly *Palms* and Ferns, lightened by some good spikes of *Gladioli* and cut blooms of *Duke of Wellington Carnation*, which were intermixed with the dwarfier plants. Messrs. Dickson & Co.'s table was devoid of colour to a great extent, some blooms of their new cutting *Pinks* and *Carnations* and the new double *Camomile* being the only flowers employed. Messrs. Todd & Co. had a large dessert table arranged with fruit and flowers, which attracted considerable attention. From the Royal Botanic Gardens Mr. Sadler furnished a table of vegetable curiosities, consisting of *Nepenthes*, *Droseras*, *Dionaeas*, *Darlingtonias*, the *Lattice-leaf plant*, a fine potful of *Senecio speciosus*, and the curious *Oxalis sensitiva*.

Turning to the competition, and taking the most popular section first—the fruit, as previously noted, the general amount was below the average of the last few years. For the collection of twelve varieties of fruit only two exhibitors staged. Mrs. Pease, Hutton Hall, Guisborough (Mr. McIndoe), being first with *Grapes Duke of Buccleuch*, *Foster's Seedling*, *Black Hamburg*, and *Gros Guillaume*; *Melons Rosebery*, *Topping*, and *Marcellus*; *Pine Apples Queen and Smooth Cayenne*; *Peaches Walburton Admirable* and *Princess of Wales*, both extra fine; and two dishes of *Figs. C. Tennant, Esq., M.P.*, *The Glen* (Mr. McIntyre), was the other exhibitor, and was placed second. For eight kinds of fruit there were again only two exhibitors—the Dowager Duchess of Athole, Dunkeld (Mr. Fairgrieve), and the Dowager Duchess of Roxburghe, Broommouth Park, Dunbar (Mr. McKelvie). Mr. Fairgrieve was also first for a collection of hardy fruits, in which were some good dishes of *Plums*. *Grapes* were very numerous shown, something like 170 bunches being staged altogether. The chief prizes were for twelve bunches, six black and six white. Four lots were staged in this class, none of them being up to the usual form seen at Edinburgh. Sir Wilfred Lawson, Bart., M.P., Brayton Hall, Carlisle (Mr. Hammond), occupied the first position with four good *Black Alicantes*, two of Mrs. Pince, and six unfinished bunches of *Muscat of Alexandria*; Mr. McIntyre being second, and Mr. McIndoe third. For eight bunches five competitors entered. Mr. McKelvie was first here with two very fine examples each of *Alicante* and *Gros Colman*, two good *Black Hamburgs*, and two large clusters of *Muscat of Alexandria*; the Earl of Strathmore, Glamis (Mr. Johnston), being second, and Mr. Hammond third. Mr. Hammond was again first with four bunches with *Gros Colman*, *Golden Queen*, *Muscat of Alexandria*, and *Alicante*. In the classes devoted to one kind of Grape, the pair of *Muscats* from Glamis, the two *Black Hamburgs* from Mr. Boyd, *Callander Park*, *Falkirk*, the single bunch of the same sort from Mr. Boyd, and the *Gros Colman* from Mr. McKelvie, and the *Duke of Buccleuch* from Messrs. Thomson, *Clovenfords*, were all especially fine. Only three of four *Pine Apples* were shown, Mr. McIntyre being first both for *Queens* and *Smooth Cayenne*, also for any other sort. *Peaches* were finely shown, the first-prize twelve of *Walburton Admirable* from Mr. Smith, *Brentham Park*, *Stirling*, being particularly fine.

In the several plant classes some fine specimens were staged. The six stove or greenhouse plants, three stove or greenhouse plants, and three *Heaths* from Mr. Paterson, Millbank; the foliage plants, *Palms*, Ferns, and table of plants from Mr. Hammond; the *Fuchsias* from Mr. Walker, Rosehall, were all particularly good. With the exception of *Dahlias* from Messrs. Downie & Laird, *Hollyhocks* from Mr. Forbes, Hawick, and *Quilled Asters* from Mr. Taylor, Inveresk, this section was poorly represented. In the vegetable section the chief

interest was in the collections of Potatoes, prizes being offered for eighteen and twelve dishes of twelve each. Mr. Reid, Mid-Sanquhar, Ayrshire, was fairly first for both collections, though a considerable amount of dissatisfaction was expressed concerning other awards. There were twelve entries for a collection of twelve sorts of vegetables, Mr. Brown being first with a fine collection. The entries for dishes of *Onions*, *Cauliflowers*, *Leeks*, &c., were numerous, and the quality generally good.

MILDEW.

THIS destructive pest which affects Vines is much dreaded by cultivators, and its work of destruction is quick and complete if allowed to go unchecked for a very short time. It is not surprising that its appearance in a vinery is startling to those in charge, and how to check its ravages without injury to the crop of fruit is almost bewildering. The opinions as to the cause of the development and the best mode of disposing of it with the least damage to the crop are numerous; but so far I have not seen any very satisfactory suggestion on the subject, nor directly pointing to what I believe to be the real cause or causes. The supposed cause is a close stagnant atmosphere, which is considered favourable to the growth of fungi, and the present remedy is sulphur and a warm dry atmosphere. The sulphur is first applied to the pipes, and these heated until the atmosphere of the house is charged with the fumes, and if this does not destroy the mildew sulphur is applied in many ways; for instance, syringing the Vines with it mixed with water, and dusting both the leaves and the bunches, but this quite spoils the appearance of the Grapes. I do not doubt that sulphur will quickly turn it black and for the time being destroy it. It is really necessary before trying to check the disease, if I am justified in so calling it, to ascertain if possible the cause or causes which have been the means of bringing it into existence. What would be the good of sulphur applied in various ways, or the atmosphere kept dry and warm, if dryness of the soil at the roots was the cause of its existence? and I am thoroughly convinced that this is one of the chief causes of mildew. It is more prevalent during hot dry summers, especially when Vines have abundance of drainage, and in a light sandy soil more so than when the soil is of a heavier texture. When the disease appears under these conditions the drier the border and atmosphere are kept the faster the mildew spreads. When first noticed the border should be carefully examined, and if it is dry it should have a thorough supply of water. No sulphur will then be needed—the water is all that is required to check it. In a vinery here early in the season of 1879 the end Vine in an inside border was attacked by mildew. I examined the border and found it satisfactory, except the end, which to my surprise was very dry. A good supply of water was at once given, but instead of soaking into the border it passed to the end wall and through the bricks. Means were at once taken to prevent this; the border was well watered, and the mildew disappeared. Again, a sudden check to Vines by opening the house by ventilating too extensively or by discontinuing the fire heat impedes the progress of the Vines and predisposes them to disease. Watering in this case would be useless, and only add to the ravages of the pest. A warmer atmosphere would require to be maintained, and under these conditions sulphur placed upon the pipes would prove beneficial.

From careful observations for some time past I am convinced that mildew can be produced by cultivators, and that it can be also prevented by them. It would be useless to argue that mildew is only caused by the two conditions mentioned, for any cause which will check the Vine or induce a diseased condition of the tissues will give rise to mildew. On this point I shall at a future time point out two striking examples that have come directly under my notice to further prove that many causes, some of them perhaps at present unthought of, will cause mildew, and that its thorough eradication is impossible without the adoption of the severest measures.

Whether the mildew that attacks the Rose and the Peach is identical with that which infests Vines I am unable to say, but this I know, that they can be produced by similar causes. Roses are much subject to it, yet it is surprising in spite of this, if due precaution is taken and the minute details of forcing carefully and practically carried out, it can to a large extent be prevented. Dryness is also favourable to the development of mildew on the Rose. Cold draughts admitted to the tender foliage in the early season soon cause it, and perhaps nothing is more striking than when forcing is attempted and the plants have not had their proper season of rest. They start into a puny growth and are overwhelmed by this disease. Hard forcing also soon gives rise to it. But if these are guarded against, very little mildew will trouble cultivators when forcing Roses, especially if the soft-soap system is carried out, which has been fully detailed in the Journal.

Peaches under some systems of cultivation are much subject to mildew, and Royal George is specially credited with being liable to it: so far I have never seen it upon that variety. It would be difficult to point out under what different conditions it is caused to develop upon the Peach than upon the Vine and the Rose. Similar causes appear to me to induce the disease in nearly all instances.—W. BARDNEY.

TOMATO THE CONQUEROR.

I HAVE to thank "SINGLE-HANDED" for kindly pointing out a mistake inadvertently made by me, when I stated (page 180) that the Conqueror Tomato was "commoner" than the Trophy. What I meant to imply was that the former is more easily grown, being a free setter, and might with advantage be employed to impregnate the latter, which sets badly in heat. "SINGLE-HANDED" seems very confident that I have grown the wrong variety. Possibly I have, and it is equally possible he may have the wrong variety: or do the Messrs. Bliss & Sons of New York supply a favoured few only, and not the trade generally? My seed packet bears the impress of Veitch & Sons, a firm noted for the genuineness of the strains of vegetable and other seeds which they distribute, and I am quite certain that my plants were obtained from that packet of seed, as the whole of them have been quite distinct from any other variety grown here during the season. The colour of the fruit is a rich cornelian red, resembling Aeme, but rather deeper than Vick's Criterion, and the fruit being corrugated is quite distinct from both. The Messrs. Sutton and Sons, another very reliable firm, give the Conqueror prominence in their "Amateur's Guide," and if their figure of it is truthful, corrugated the variety undoubtedly is. Will "SINGLE-HANDED" kindly send me a fair sample of fruit of his presumably true stock through the Editors or otherwise? as I must confess that I am somewhat sceptical with regard to its being "no more corrugated than an egg," in this respect differing, according to his opinion, from every variety mentioned in the list I gave on the page above quoted. I thought some of the smaller varieties were nearly perfect in that respect. Others no doubt have grown the Conqueror, what is their experience with it?—W. IGGULDEN.

[Mr. Iggulden has sent us fine fruits of the Conqueror which are slightly corrugated, examples of Vick's Criterion very faintly corrugated, with several fruits of the following small varieties—Nesbit's Victoria, oval; Dickson's Queen of the Tomatoes, pear-shaped; and Burghley Pet, round—all without speck, line, or wrinkle, therefore absolutely smooth.—EDS.]

VEGETATION IN SMOKY ATMOSPHERES.

It will not only be interesting but useful to dwellers in high altitudes surrounded with smoky atmospheres, of which there are so many in England, to know what kinds of trees, shrubs, and flowers are best suited to plant for shelter and for ornament in these situations. No better illustration of this can be found than at Dowlais House, Glamorganshire, which is in the centre of those great ironworks, the fame of which is known among all industrial communities in every part of the world.

Dowlais is 1000 feet above the sea level, and is surrounded by lofty chimneys giving forth clouds of sulphur-laden smoke, and fiery furnaces glaring with frightful fury—hundreds of them. One would fancy that no vegetation could exist in such a place; and although the plants are few that are to be found there, it may be instructive to know what they are.

It is sixty years or more since the plantation surrounding Dowlais House was planted as a shelter against the prevailing winds, and as an ornament to the place. Up to the present time the trees of which this is composed are not higher than the house itself, and still they are in perfect health. They are neither stunted nor deformed, but have the appearance of healthy dwarfs, doing their best to make themselves useful in the position where their lot is cast. The plantation consists of Elm, Ash, a few Black Poplar, and Hawthorn. The first three represent the healthy dwarfs, but the last seems quite at home, and attains a good average of that tree, being in proportion much larger than any of the others. From this we may learn the lesson that the Hawthorn is a tree well adapted for smoky atmospheres, and that the others that have been named, though not luxuriant, serve a purpose which, perhaps, no other trees would serve so well. The shrubs are few, Lilacs, struggling Rhododendrons, and *Lycium europæum* being all that were observed.

Of garden flowers the number which succeeds there is almost as limited as is that of the trees. Notwithstanding the persevering efforts of Mrs. Clark, who has bestowed more attention on her ungrateful flower beds than many do upon theirs who are

more highly favoured by soil and situation, she fails to rear those objects she so much loves. Her labours are not, however, wholly unrewarded, for in few places, or, indeed, in any place, have we seen such masses, and these so numerous, of the old Clove Carnation as at Dowlais House. There it luxuriates, and it is not unusual to see one plant covering a surface of nearly 3 feet in diameter. At the present time the garden is quite red with this fine old flower. Several species of Iris succeed well, and of these *I. pallida* and *I. foetidissima* are the most luxuriant. The London Pride knows no bounds to its vagrant habits, and rambles everywhere, blooming abundantly. Well may it be called London Pride, for it seems as if it would revel in the smoke of the great city. The Sea Pink (*Armeria maritima*) vies with the London Pride in its endeavour to win the smile of their generous patron, and in this it succeeds to perfection. The Gardener's Garter (*Elymus arenarius variegatus*) and the common Monkshood are dotted about here and there; but there are large masses of *Saxifraga ligulata* and *Veronica spicata* which seem to be perfectly at home. These with *Centaurea montana*, and here and there an *Auricula* struggling to hold its own, are the flowers that adorn the garden at Dowlais.

Although the garden at Dowlais House cannot boast of its outdoor riches, the deficiency is amply compensated for by the success of the indoor productions. There are not in all Glamorganshire better bunches or more highly flavoured fruit of Muscat of Alexandria Grapes than are to be found there, and these are quite rivalled by the well-developed Black Hamburgs. Pines are grown in large quantities, and in a style which calls for admiration. It would have taxed the strength of many a more pretentious establishment to have produced a clothes basketful of such Pines as we saw Mr. Boyce the head gardener and one of his men staggering under towards the room where Mr. and Mrs. Clark entertained the President and members of the British Association to a sumptuous luncheon, when they came by special invitation to see these ironworks. The collections of stove and greenhouse plants are varied and good, and the success with which they are cultivated is great when the untoward circumstances under which they are grown are taken into consideration.

SOUTH SHIELDS AND WESTOE FLORAL SOCIETY.

THIS old-established Society held its thirty-seventh Exhibition in the Cricket Grounds at Westoe on the 10th and 11th inst. The prize schedule was very liberal, and a most successful show was the result. The Society offered £10 for first for six stove and greenhouse plants in bloom, and five other prizes besides. This brought out eight competitors, many of the plants being in excellent condition, and fresh for the lateness of the season. The Show was held in a very large oblong spacious marquee. The flowering, foliage, and Ferns were placed on the centre stage slightly raised.

Messrs. John Thompson & Sons, nurserymen, Newcastle, were first for the six plants in the open class with a large *Stephanotis* very fresh, a good *Erica Fairriana*, *Bougainvillea glabra* well coloured, *Dipladenia amabilis*, *Lapageria rosea*; Mr. Battensby, Hagg Hill, being second, staging good plants of *Ericas* *Eweriana* and *Marnockiana*, the latter excellent. Messrs. Gardner, Dunston, and Mr. Morton, North Shields, were awarded equal thirds, the former possessing a fine plant of *Vallota purpurea* with over thirty spikes of flowers. For three stove or greenhouse plants in bloom J. C. Stevenson, Esq., M.P., Westoe (Mr. Smailes), was first, his best plants being *Allamanda Wardleana* very fresh, and *Erica Marnockiana*. Joseph Eltringham, Esq., Westoe (Mr. Watson), was second, his best plant being a very fresh example of *Cassia corymbosa*. It is seldom this plant is seen in better condition than in the north. For three fine-foliage plants Mr. Thos. Wilson, Gateshead, was first, Mr. Smailes being first for three decorative plants. The show of *Coleuses* was excellent, filling up one-half of the tent, and were quite a speciality. Mr. Smailes was first for three. Cockscombs were excellent, Mr. Bampton, Sunderland, showing a dwarf variety over 16 inches across. Mr. Watson also showed three grand *Vallotas*, Mr. Watson and Mr. Allan taking the remaining positions. Zonal *Pelargoniums* and *Fuchsias* filled up portions of the Show, and were in good condition.

Florists' flowers were superior, the Dahlias, Hollyhocks, and Gladioli being considered the best that have been exhibited in the north this year; but nearly all were shown unnamed. This defect was strikingly apparent in nearly every other department. Messrs. John Thompson & Sons were first for twelve spikes of Gladioli, and also first for twelve Hollyhocks; the latter were truly excellent, being very large in size and fine in quality. Some of the flowers were over 5 inches across. For six and twelve Dahlias Messrs. Walker, Low Fell, and Smith, Gateshead, were the prize-takers, with some excellent flowers as regards size and quality.

Fruit was not numerous, but some average bunches of Grapes were shown, especially those shown by Mr. Smailes, who won for two black bunches with Black Alicante in superior condition;—Williamson, Esq., Whickham (Mr. Lawson), being second with two fine bunches of Black Hamburg, well finished, but not nearly the size of

Mr. Smailes'. The latter was also first for two bunches of Muscat of Alexandria, averaging 3 lbs., large in berry, and of a richer amber in colour. Mr. Lawson also showed some good Peaches. Vegetables were excellent. With the perseverance of the Treasurer (Mr. Easton), and Secretary (Mr. Dobby), this Show, already good, will no doubt improve annually.

Not for competition were a stand of Phlox Drummondii, containing some excellent flowers of a rich violet shade, by Thos. Binks, Esq., South Shields (gardener, Mr. Bone); Mr. John Hinde contributing a stand of dwarf Capsicums, finely coloured, and the foliage of a rich glaucous green.

FUNGI A RESULT, NOT A CAUSE OF DISEASE.

WHY should "S." entertain feelings of regret "that our opinions regarding the relation of fungi to diseases in plants are entirely at variance?" The earnest tone of his communication shows at any rate that we are at one in that respect, and if by discussion we can obtain a better light to aid us in our search after truth there can be nothing to regret. Both "S." and Mr. Harrison Weir invite me to support my views by something more than mere assertion; and gladly do I hasten to do so, for the subject is one of considerable importance, erroneous views of it undoubtedly leading to wrong and probably mischievous attempts to obtain a remedy.

Taking the Potato disease first as an example with which we are all unfortunately familiar, when are fungi perceptible in the Potato? Before the plague spot appears or afterwards? Invariably afterwards; and mark this, If the weather continues hot and dry after growth ceases in the tubers no plague spots appear, and consequently no fungus, but the haulm decays naturally and the crop is safe and sound. Observe further, that if upon growth ceasing in the tubers showers occur only for a day or two, plague spots promptly appear, and continue to spread to the serious hurt of the crop, no matter how hot and dry the weather may be afterwards; so that the disease may be seen spreading in weather the reverse of favourable to the growth of fungi, or, in other words, not affording the "particular temperature and moisture necessary" to its growth. Advocates of fungi as a cause of disease have no reason to complain of discourtesy or neglect in this particular instance, for the matter was fairly tried out at Chiswick, the Royal Horticultural Society allowing a leading advocate of the theory and well-known fungologist to apply his specific, termed "Salus," to a plot of Potatoes, without effect!

Peach blister occurs in spring, and only in spring. It attacks tender foliage and the epidermis of young branches that are exposed to the scathing influence of cold winds from the north-east that are then usually prevalent. Protect the young growth from the cold winds and no blister appears, and consequently no fungi. I have proved this year after year in a variety of ways, accounts of which have from time to time been published in the Journal. Observant men of established character and position in various parts of the country have likewise proved it, as, in fact, anybody possessing ordinary powers of observation may do. Let us not forget that the midsummer growth of Peach trees is equally tender, equally sensitive to blight in "leafy June," when a genial temperature and frequent showers—so favourable to the growth of fungi—prevails, and yet no fungi appears, simply because there are no cutting blasts to blister the foliage and produce a suitable medium for its spores to vegetate in.

If shanking of Grapes is caused by a fungus, how is it that I have Vines growing in the same border under precisely similar conditions, some of which have not a faulty berry and others have shanking more or less in every bunch? Experience enables me to assert that overcropping is the cause in some instances and debility in others. I hope to renew that portion of the border in which the Vines showing tokens of debility are growing, and if this is done thoroughly one may look forward very confidently to a thorough cure next year. The fact of the fungus only being found upon "the little pieces shanked" of otherwise fine bunches to my mind affords positive proof of it being a result of disease. If it were not so, what is to prevent the mycelium from spreading over the entire bunch?

Mr. Harrison Weir's denial of the existence of an analogy between plant and animal life is decidedly in opposition to the teachings of modern science. This may perhaps best be shown by a brief quotation or two from the teachings of a professor of vegetable physiology:—"We lop off the early shoots of our fruit trees in order to direct the nutriment into the flowering and fructifying parts, instead of allowing it to be spent in the growth of (to us) useless new tissue. The creeping roots of our Strawberries are religiously cut off for similar reasons; for in this case, as in some of that of the lower animals, propagation takes a two-fold shape—by flowering (as animals by eggs) and by means of a stoloniferous root (as such animals as compound corals and hydras by that process termed budding). Every plant, therefore, is as

distinct an individual as a coral animal, and is even better able to propagate new individuals. One does so by specialising certain parts of the tissue to form ova or eggs, the other to form seeds. The analogy may be carried further still. All animals are provided with a certain store of nutriment to assist in their growth until they can obtain sustenance for themselves. In the eggs of all living creatures the bulk contains three-fourths of such stored-up material, which is unconsciously and imperceptibly absorbed into the structure of the newly developed animal. Similarly as is seen in our beans, peas, acorns, &c., there is a supply of albumen and starch for the nourishment of the young seed germ until it can strike root into the ground on its own account, assimilate the soluble mineral matter it finds there, and deoxidise the atmosphere of its necessary aliment."

The subject is so seductive that one might fill many pages in refutation of Mr. Harrison Weir's singular assertion. Fruits and leaves absorb carbonic acid and give out oxygen by day; at night this chemical action is reversed. All the various substances now known to exist in the atmosphere are found alike in vegetable and animal bodies, and bear a direct relation to organic life; moreover, the atmosphere contains in an elementary form nearly all the substances found in vegetables, just as it does most of those found in animals.

Bernays' "Student's Chemistry" throws great light upon the intimate analogy in existence between plants and animals. Speaking of the diffusive power of gases he says:—"But for this law there could be no life. Vegetation must languish and die for want of a supply of carbonic acid, which by this provision is wonderfully and completely diffused throughout all the particles of air. The watery vapour, of no less importance, would not keep flexible the skins of animals and supply parched vegetation with rain and dew. In the process of respiration the minute cells of the lungs, in which the aëration of the blood takes place, would not be emptied at each exhalation of the heavy carbonic acid which they contain, but the operation would after a few minutes be suspended, and death inevitably ensue."

This last quotation will, I hope, carry conviction to every thoughtful mind that the same natural laws affect in a very similar manner animal and vegetable life, and tend to prove that very similar conditions are alike necessary for health. To enforce the lesson in more homely phraseology I may add that fresh air, wholesome food, and cleanliness are alike good for animals and vegetables, and the want of them causes sickness and debility in both.—EDWARD LUCKHURST.

HYBRID ODONTOGLOSSUMS.

I MIGHT have been a little more explicit in my remarks on the hybrid *Odontoglossum* in my descriptive notes of Lee Hall on page 192. The hybrid alluded to has not been raised by Mr. Glover, but I understand was found amongst some imported Orchids that were purchased; it proved to be quite distinct, and is supposed by good authorities to be a cross between *Odontoglossum luteo-purpureum* and *O. Lindleyanum*.—WM. BARDNEY.

CONCERNING "SINGLE-HANDED'S" inquiry about hybrid *Odontoglossums* on page 235, I believe he is correct in stating that we have no evidence as to a hybrid having been obtained between any two species of that genus in this country. But at the same time there are several forms that are reasonably regarded as "natural hybrids," from their being intermediate in character between other species. The best known of these probable hybrids are *Odontoglossum Humeanum* (*O. cordatum* and *O. Rossii*), *O. Murrellianum* (*O. Pescatorei* and *O. nevium*), and *O. Coradinei* (*O. triumphans* and *O. odoratum*). As regards *Cattleya Manglesii* Mr. F. W. Burbidge, in his work on the improvement of cultivated plants, states that *C. Mossii* was the seed-bearing plant crossed with *C. Loddigesii*.—D.

THE POTATO DISEASE.

THE extract from the *Times* I put at the end of my last communication does not appear to have given general satisfaction, although I think the remarks are true in the main. One part of it is perhaps not altogether correct—*i.e.*, that gardeners have been careless about their seed Potatoes. Some of them I know have been careful with those tubers selected for seed. I still adhere to my original statement, but in referring to the apathy of the growers, &c., my observation was a general one, and not intended to apply to any particular class. Having quoted from a leading article in the *Times* I will now refer to one in the *Daily News* of 23rd August last—"The agricultural returns lately published show that in Great Britain alone 550,931 acres have been planted with

Potatoes in the present year, and over a considerable portion of this vast area the disease has seriously affected the plant. To some extent this is the fault of the cultivators themselves. It is only by the large grower that the Potato has anything like scientific culture. In Ireland the great bulk of the crop is produced by small farmers, who sow every second year in the same ground, use the smallest tubers for seed, and take no precautions whatever against blight. The same may be said of the great mass of the smaller growers in England and Scotland. They go on with the same variety long after it has begun to degenerate, and make the worst part of one year's crop the seed for the next year, and probably bury the diseased haulm in the Potato field itself." The above remarks agree pretty well with mine, and the truth of them is borne out by the excellent crops obtained in Ireland this year, in consequence of the people having been supplied with a good sample of Scotch Champion, and as far as I can understand there will be double the produce they formerly obtained.

Your Lincolnshire correspondent has read my book, it appears. I am very pleased to hear he has a copy, but I wish he would read it more carefully, for he would then see that on page 66 Potatoes are only recommended to be planted 5 inches deep on light land, such as in the neighbourhood of the Cotswold Hills, and that on heavy land the reverse plan is recommended. With regard to the merits or demerits of the book it is not for me to speak. It has been reviewed in several of the leading journals, and well spoken of. It has been adopted by the Irish Government as the official reference book as to the disease, and I have received letters of approval from all parts of England, which ought to be enough to satisfy anyone.—THE WRITER OF "THE POTATO DISEASE AND HOW TO PREVENT IT."

A WEEK IN YORKSHIRE.—No. 2. OAKWORTH HOUSE — THE WINTER GARDEN. (Continued from page 241.)

IN my last notes on this extraordinary garden it was stated that Mr. Holden's mansion was situated within a very short distance from the public road that traverses the village. This road skirts what in a flat district might be termed a range of hills. It will render the position intelligible to say that the road runs east and west, and on the right hand side, travelling westward, the ground rises somewhat abruptly to a considerable altitude; on the left is the picturesque vale, in which Haworth is conspicuous with its new church and old spire. Oakworth House being immediately at the foot of the rising ground mentioned, and the winter garden being in the rear of the mansion, and the other glass structures again in the rear of the winter garden, it follows that to obtain the necessary levels a considerable extent of quarrying was requisite, for the hill is composed of a dense mass of Yorkshire stone. Had the ground whereon the horticultural edifices are erected been uniformly level the work done would have been of great magnitude; but when we consider that the entire area of the winter garden had to be excavated out of the solid rock on one side or end to the depth of, apparently, from 15 to 20 feet, the undertaking appears to have been little short of stupendous—such an one that only a man who had spent a life in facing difficulties and conquering them could have entered on and carried it out so completely, thoroughly and successfully.

To commence, then, with the erection of this large winter garden, which, as before mentioned, covers an area of nearly half an acre, the site had to be quarried to the extent indicated, the stone being in part utilised in the formation of the huge rockeries that have been previously alluded to. The building is square in form, or nearly so—a side entrance from the front being through arches of rocks between the mansion and chapel; but the principal entrance is directly through the mansion, which is singularly complete, elaborate in its ornamentation, yet chaste and rich.

Considering that the planting and furnishing of this winter garden was only commenced last autumn, its appearance cannot fail to astonish the visitor on obtaining his first glance of the interior. Five large beds occupy the central portion of the building, and extend almost its entire length. On the margins of these beds the hot-water pipes are arranged, enclosed in ornamental gratings, coped with an iron cornice, the "walls" being about 2 feet high. At intervals along the top are vases for groups of plants alternating with pillars or pedestals for individual specimens; and between these, on the top of the walls or curbs, ornamental-foliaged and flowering plants in pots are arranged. The vases are furnished with Yuccas, Ferns, a few flowering plants, and *Tradescantia zebrina*; but ordinary flowering plants, such as *Pelargoniums*, &c., are necessarily transient so far from the glass, especially in summer, and more of such plants with persistent and ornamental foliage will probably be found more satisfying. For

the pedestals such plants as variegated Yuccas, Aloes, Euryas, *Dasyliions*, and others of the same nature would have a fine effect, and would improve yearly in value and beauty. Such plants are already represented, and in due time the number of them will be probably increased. Planted out in the beds are the permanent specimens—Palms, Cordylines, Cycadaceous plants, Tree Ferns, Camellias, Oranges, Sikkim Rhododendrons, variegated Euryas and Yuccas, *Theophrastas*, *Araucarias*, *Acacias*, *Grevilleas*, &c., with *Eucalyptus globulus* planted near the pillars, to which the trees are trained, and which are making rapid and healthy growth. The girders of the roof will eventually be covered with climbers, several of which have been planted, and some are making good progress. A structure of this kind affords suitable positions for a great variety of climbing pillar plants, of which the following are examples:—Of the *Tacsonias*, such as *T. exoniensis*, *T. Van-Volxemi*, and *T. mollissima* are all suitable; and of the *Passifloras*, *Comte Nesselrode*, *Impératrice Eugénie*, and *cærulea racemosa* are among the most useful. On the cool moist part of such a building *Lapagerias* would thrive, and in the lighter positions *Clematises*, *Bignonias*, *Mandevilla suaveolens*, and the fragrant *Pergularia odoratissima*, with *Habrothamnuses*; *Acacias dealbata*, *oleifolia elegans*, and others; *Plumbagos*, *Rhynchospermums*, *Jasminums*, *Bomareas*, &c. Some of these are already represented, and in due time such plants will have an elegant appearance.

At the end opposite the mansion the effect is strikingly picturesque, original, and unique. The excavations were not carried to the extreme end of the building, but were stopped some 20 feet short of it, leaving the natural face of the rocks about as bold and rugged as the mind can imagine. With good taste in designing and careful execution of the work, a most imposing effect has been produced here. A chasm has been made to form the bed of a cascade, down which the water rushes, not in a smooth stream as if from a trough, but in a series of jumps and bounds, breaking it up like a mountain torrent as it dashes into the pool below. On either side of this cascade are large caverns with dark and twisted passages—a cool hermit-like retreat, in striking contrast to the more artistic scene of the ornate building and its diversified vegetation. In suitable positions at the front of this precipice, and on ledges on its rugged face, are large plants growing freely—*Phormium tenax variegatum*, *Latanias*, Tree and other Ferns, Yuccas, and many others that it is not necessary to enumerate. This boldly indented and broken face of rocks and vegetation, which extends across the building, may possibly be about 15 feet high, and on the top is what may be termed a balcony garden of considerable extent, and certainly original in design. This is reached by two twisting flights of rude stone steps, appearing as if hewn out of the solid rock—one flight on each side of the building; but we ascend to the balcony by another and a much longer route.

It must be said now that the pleasure ground side of the winter garden is of glass from the roof almost to the ground, the other side being a wall of rocks. A great deal of this is artificial, but so admirably executed as to appear most natural. At the base are rough boulders that lie in the bed of a tortuous stream, which meanders along under the shade of Ferns. In this wall of rock large irregularly-shaped mirrors are embrasured at intervals, by which the entire garden is reflected, this apparently doubling its size and giving a tropical forest-like appearance to the scene. At the mansion end of the building we step across the stream, and a narrow path leads to a door in the side of the building. Near this door is apparently the weather-worn trunk of a huge Elm—an exact resemblance of a monarch of the forest, with its big arms sawn off at short distances from the trunk, the hollow extremities of which form receptacles for plants—*Aspidistra lurida variegata*, Aloes, and on the summit a fine specimen with large gracefully drooping fronds of *Enecephalartos ampliatus*. Nearing the tree we find it not so old as it at first sight appeared, and instead of its having weathered the storms of centuries it had been raised in a few months by skilful French artists, for its substance is cement. Passing partly round the gigantic trunk we find a fissure, just large enough to admit a man whose curiosity naturally impels him to enter. Inside he sees a sort of corkscrew arrangement of rough stones; these he ventures to climb, to look out of the top of the remarkable cylinder, but reaching the summit he is surprised to find that he is by no means at the end of his journey. He finds himself at the end of a rocky parapet, his head nearly touching the roof; and on he goes, now stepping across an apparent fissure, now on a boulder. He follows his irregular yet perfectly safe track, and looking down admiringly on the scene below and with feelings of astonishment at his position above he eventually finds himself in the balcony garden before mentioned at the opposite end of the building. This elevated portion is still a considerable distance from the roof, and there is ample height

for Palms, Tree Ferns, and other ornamental plants that attain a considerable size. The balcony is rendered extremely attractive by the tasteful association of rockwork, water, knolls, borders, and curving walks. Near the margin of the precipice is on one side a splendid specimen of *Latania borbonica*, and on the other a fine *Cycas circinalis*. These are what may be termed the two corner plants. They are planted on *Selaginella*-covered mounds, and have a fine effect, both as seen from above and below. Amongst the rocks are individual plants of *Yuccas*, *Aloes*, *Ferns*, *Camellias*, &c., and in the pools are *Water Lilies* margined with *Ferns*. It is from here that the water is "turned on" and the cascades burst out, the water rushing down its rocky bed into the pool below. And not here alone does the water issue, but from various points all along the side of the building, the parapet of which we have just traversed, it splashes, and dashes, and foams, pursuing its headlong course in the stream below, and flows into culverts at the opposite end of the building. When the full water force is on and the supply is unlimited the roar of the several cascades is half deafening, and on a hot day highly refreshing. When the face of the rocks becomes more clothed with vegetation (some of the choice variegated and other *Ivies* would thrive and look well here) the effect of this splendid house will be grand; it is fine now, and it is astonishing how much has been done in the way of planting and furnishing since the work commenced.

As was mentioned last week, the floor of the winter garden is of mosaic work wrought in chaste designs and executed in the most skilful manner. Considering the extent and artistic character of the work it has no equal that I am aware of in any other structure of the kind in the kingdom. Few of the pieces of marble employed appear to exceed half an inch square, and when it is remembered there are probably a thousand square yards of this mosaic flooring some idea of the magnitude of the work may be formed.

In connection with this remarkable structure is a billiard room and Turkish baths, all furnished in the most complete manner. Preparations are being made for illuminating this winter garden with the electric light, which, according to Dr. Siemens' experiments, has such a striking and beneficial effect on vegetation. Mr. Holden has certainly a fine field for testing it; and as we are indebted to him for so much light—the lucifer match—his enterprise may yet place us under further obligations with the highest and most perfect of all modes of artificial illumination in connection with the growth of plants and trees.

Sufficient has been said to show that Mr. Holden's winter garden is no ordinary structure; it is in fact extraordinary both in conception and execution, and owner, architect, and gardener are alike to be congratulated on its condition. It will improve with years, and all will share in the hope that Mr. Holden may long enjoy the splendid structure that he has at such great cost and labour succeeded in bringing to its present very advanced state of completion.—A RAMBLER.

THE Committee of the MAIDSTONE CHRYSANTHEMUM AND FRUIT SOCIETY, which is under distinguished patronage, have issued a liberal schedule. We observe that a class is provided open to all England for thirty-six incurved blooms, distinct, of large-flowered *Chrysanthemums*, the first prize being a silver cup value £10 10s., the remaining prizes being £4 and £2 respectively. There is also a class for eighteen plates of Apples, distinct varieties, open to all comers, the first prize being a silver cup value £5 5s., offered by H. A. Brassey, Esq., M.P.; the second and third prizes of £2 2s. and £1 1s. being offered by Roger Leigh, Esq., M.P. Lord Holmesdale also offers a silver cup, value £5, in the county section for twelve specimens of large-flowering *Chrysanthemums*. Sir E. Filmer, Bart., M.P., Sir John Lubbock, Bart., M.P., and Sir Sydney Waterlow, M.P., are also among the donors in the prize list. A Society thus well supported, and in a fine district for fruit culture and good gardens, ought to produce a very large and fine exhibition.

— A PRACTICAL and successful cultivator writes as follows

relative to WATERING, TRENCHING, AND MULCHING :—"We have to thank a system of deep trenching for carrying us well through the late drought, so that Peas, French Beans, Vegetable Marrows, Lettuces, Endive, and young Cabbages, are now plentiful. Slight mulchings of half-decayed manure placed between the crops were of the greatest value. Asters, Pansies, Carnations, Marigolds, &c., have been without water. Dahlias we have watered to keep the plants on flowering and to increase the size of tubers for stock purposes. Gladioli have been extra fine with us this year; these have had one thorough good drenching of water in order to swell up the corms for next year's blooming. Pentstemons have also had to be watered in order to produce a sufficient number of cuttings, the flowering having exhausted some of the plants so much that no cuttings were to be had."

— THE annual autumn Exhibition of the BRIXTON, STREATHAM, AND CLAPHAM HORTICULTURAL SOCIETY will be held in the Lecture Hall, Streatham, on November 11th and 12th. The exhibitions of this Society have gone on steadily improving since the Society was established. The district appears to include many good cultivators, and in every section the exhibits have been highly creditable, specimen *Chrysanthemums* having been generally exceptionally fine. Good prizes are offered for them this year, also for cut blooms, and several classes are devoted to stove and greenhouse plants, fruits, and vegetables. The Society appears to be admirably managed, and unquestionably possesses a competent Secretary in Mr. Hall. The coming Show will no doubt rank amongst the best of suburban exhibitions.

— A CORRESPONDENT writing from the neighbourhood of Wimbledon says :—"I often wonder that the HARDY STATICES are not more frequently grown in gardens, as they are certainly very attractive, and just now are with me in fine condition. One species that I especially admire is *Statice tatarica*, of dwarf habit, bearing an immense inflorescence of small flowers with silvery white calyxes and rosy-coloured corollas. *S. densiflora* is another pretty species, compact in habit, with numerous purplish blue flowers. *S. Limonium*, the well-known British species, is not less pleasing, the foliage being very large, of a deep shining green colour, and the large spreading inflorescence is crowded with very small pale purple flowers."

— AT the BRIGHTON HORTICULTURAL EXHIBITION an incident occurred showing how careful it is necessary for intending competitors to be when giving notice of entry. The Corporation cup, offered for a collection of fine-foliage plants, was awarded for the specimens from Handcross Park, Crawley, Sussex, but by mistake the name of Mr. Rann's foreman was printed on the prize card and engraved on the cup. He had, it appears, conducted the correspondence in reference to exhibiting, and thence the error arose. At the same Exhibition the Directors of the London, Brighton, and South Coast Railway most liberally provided free carriage for all exhibits from any station on their line to Brighton and back again.

— RELATIVE TO PLANTING SHRUBS AND TREES NEAR THE SEA, Mr. B. Cowan writes as follows :—"I should feel glad if any of the readers of the Journal who have lived near the sea would give me their advice as to what trees or shrubs endure the strong saline air, and are also not affected by the manufacture of chemicals, such as alkalis, muriatic acid gases, &c. When the wind is in the east we get the breezes direct from the sea, and when in the west the air is quite thick, and at times strongly impregnated with the smell of alkalis. I am extremely anxious to plant, but am at a loss to know what is best to do. Nothing seems to stand here but Elders; I therefore feel inclined to plant belts of them for shelter. Can it be explained why Elders withstand the effect of chemicals? Is it through any peculiar chemical constituent they contain?"

— AN extremely ornamental example of *EUONYMUS LATIFOLIUS* now attracts attention in the Cambridge Botanic Garden. It was Loudon's favourite, who thought it finer than all other species. This tree shows he was quite correct. It has very large pendulous fruits in profusion, and the effect is enhanced by the orange-coloured seeds of the bursting capsules. The leaves are large, and just now are assuming the red autumn tint for which alone the tree is valuable.

— A CORRESPONDENT, Rev. A. Fitch, will feel greatly obliged if any of our readers can give the years in which the following varieties of Potatoes were introduced:—Fox's Seedling, Rivers's Ashleaf, Myatt's Ashleaf, and the Lapstone.

— AN old but seldom seen plant—viz., *ISOTOMA AXILLARIS*, an ally of the Lobelias, was recently flowering in the grounds devoted to herbaceous plants at Kew. It is dwarf, rarely exceeding a foot in height. The leaves are narrow, irregularly and deeply cut down the margin, and dark green in colour. The flowers are borne singly in the axils of the leaves on slender peduncles several inches long; the corollas are long and tubular, with a pale lilac blue limb of five spreading divisions. It is easily grown, and the delicate tint of the flowers is very distinct and pleasing.

— A CORRESPONDENT informs us that AN EXHIBITION OF CUT FLOWERS was held at Maidstone on the 8th inst. by the Gardeners' Mutual Improvement Society of that town. Asters and Phloxes were especially well shown, but Dahlias were not very abundant. The chief prizetakers in the classes for the two former were Mrs. Brook, Manor House (Mr. J. Godden); Miss Farmer, Leeds (Mr. R. Brown); Lady Lennox, Mereworth (Mr. Jeffery); Messrs. Hollingsworth (Mr. H. Exall); F. Pine, Esq. (Mr. Hepworth); and J. Moneton, Esq. (Mr. J. Mills). Grapes were shown by J. Whatman, Esq. (Mr. McLean), and by Messrs. Exell and Morris. The arrangements were conducted by Messrs. Frost and Harrison.

— MR. EWART of Apethorpe Gardens, Wansford, Northamptonshire, informs us that in April last he planted 6½ lbs. of SUTTON'S MAGNUM BONUM POTATO, and when the crop was dug on the 9th inst. the produce was found to weigh 231 lbs., all sound table Potatoes.

— AN observant cultivator speaks in the following eulogistic strain concerning the SCOTCH CHAMPION POTATO:—"A friend of mine has at least 500 acres of this variety, and not a sign of disease among the whole of it. I, too, have grown the 'Champion' to some extent, but not so largely as above noted, and I am of the opinion that as a disease-resister and bountiful cropper it is unrivalled. If anyone should ask me how we are to avoid the Potato disease I would answer—Grow the Champion, even though it cannot be lifted until November."

— A VERY common error in WINDOW GARDENING is that of attempting too much. Too many plants are crowded into the little space at command, so that it is impossible to give each the air and light it should have. Again, plants of too diverse character are brought together. It is no uncommon thing to see tropical plants, and plants from the temperate zone, if not even alpine plants, all crowded into the same window and subjected to the same temperature and treatment. Better far to have one healthy well-grown plant that will yield its flowers in perfection than a dozen sickly, feeble, wretched plants, that have no beauty either of leaf or blossom.

— REPORTS about the serious damage done by last winter's frosts to the VINES AND FRUIT TREES IN GERMANY, the extent of which is now being realised, state that in the district around Fulda over fifty-five thousand fruit trees have been killed, being about one-fourth of all in the district. The Vines seem to have

fared better. The stock has suffered in many cases, while the root is still vigorous. But the injury even to the Vines will be felt for some years. The Roses also have suffered greatly. The Tea Rose has almost disappeared throughout the Rhine valley, and even the common Dog Rose has been quite destroyed in many places. The deep valleys suffered most, while elevated slopes and open places escaped with minor losses.

— WE learn that MR. MATTHEWS of the Royal Pottery, Weston-super-Mare, was awarded a large silver medal for a display of terra cotta vases and garden pottery at the Wirral and Birkenhead Agricultural Society's annual Show held at Birkenhead on the 8th and 9th inst.

— AN American contemporary refers as follows to Mr. JOHN H. PARNELL'S (brother of Mr. Parnell, M.P.) PEACH ORCHARD IN ALABAMA. This orchard is a field of 250 acres, containing about eighty thousand trees. In a good season Mr. Parnell sells one hundred thousand boxes, or a million and a half pounds weight, of Peaches. Our contemporary says that Parnell's Peaches are renowned throughout the States, and that his shipments reach the most distant cities of the American Continent.

EARLY HARVEST APPLE.

I CAN fully confirm, if confirmation were needed, the recommendation in your correspondents' column of last week, that this Apple should be grown in all collections. It is there stated to be adapted for dwarf and espalier training when grown on the Paradise stock. It is also, it may be added, equally well adapted for standards on the Crab stock, on which it grows healthily and freely in ordinary good soil. About fifteen years ago I planted several varieties of Apples, and none has given more satisfaction than Early Harvest. It is one of the finest trees of all now, and bears good fruit freely. Although not particularly handsome in appearance, the fruit is often above medium size, juicy and refreshing, and is much esteemed in hot weather. I was not previously aware that this Apple was of American origin; that, however, is no drawback, for it is now quite naturalised, and succeeds as well as any other early variety that I am acquainted with in English gardens. Those who want a few pecks or bushels of juicy and palatable table Apples during harvest cannot do better than plant trees of this useful and too little known variety.—A. M. C.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 14TH.

DAHLIAS constituted the most imposing portion of the exhibits at this meeting, the collection from Mr. H. Cannell being especially fine. Messrs. Keynes and Rawlings also contributed largely. Mr. J. Roberts' group of dwarf Scabious attracted much attention. The ornamental Oaks from Messrs. C. Lee & Son, and the vegetables from Messrs. Stuart, Mein, & Co., were the other chief features of the meeting.

FRUIT COMMITTEE.—John Lee, Esq., in the chair. The fruits and vegetables submitted to the Committee were not very numerous. Mr. W. Crump, The Gardens, Blenheim, was awarded a first-class certificate for a seedling red-fleshed Melon named Blenheim Orange, a handsome fruit of moderate size, globular in form, finely netted, with a great depth of flesh and of good flavour. The seeds were stated to have been taken from a fruit that gained first prize in a competition of over thirty fruits at the Royal Horticultural Society's summer Show, June 8th, 1880. The form originated by crossing Read's Searlet-flesh with Hero of Bath. Mr. Crump finds it very prolific and quick in ripening. Mr. Roberts, The Gardens, Gunnersbury Park, sent a fruit of a seedling Melon that had been grown in a cold frame. It was of good size and fair flavour. Mr. Harrison Weir, Weirleigh, Brenchley, Kent, sent samples of Diamond Plum to show the effects of stock on scion; the fruits gathered from the variety on the Sloe stock being much smaller than those from a plant on the Mussel stock, though there was no difference in flavour. Mr. George Bunyard, Maidstone, sent a new Pear named Dr. Jules Guyot, a very handsome Pear, but not quite ripe. Herr Ernest Benary's Tomatoes, Turk's Turban and White Apple, were shown from Chiswick, both in good condition. From the Society's garden came also a dish of Malakovna Apples, a Russian variety of moderate size and rich crimson colour. Samples of Red Flat Egyptian Turnip Beet and Guernsey Half Long Parsnip, a variety sent to Chiswick by MM. Vilmorin, Andrieux, et Cie., Paris, were also exhibited. J. Southgate, Esq., Selborne, Streatham (gardener, Mr. J. Salter), sent eight fine fruits of a Cucumber named Selborne Rival, a cross between Marquis of Lorne and Tender and True. It was characterised by the Com-

mittee as "a very handsome and promising Cucumber, but deficient in flavour, which may be owing to the lateness of the season." They requested that fruits should be submitted again in the full season. Mr. John Edwards, The Gardens, Acton Burnell, Shrewsbury, sent examples of Victoria Kidney Potato, which is to be sent to Chiswick for trial. Messrs. Stuart, Mein, & Allen, Kelso, N.B., staged a large collection of vegetables, including eighteen dishes of Potatoes, nine of Onions, four of Turnips, and one of Peas, besides Cauliflowers, Cabbages, Leeks, Beet, Celery, and Vegetable Marrows. A cultural commendation was awarded.

FLORAL COMMITTEE.—James McIntosh, Esq., in the chair. As already indicated the chief display consisted of Dahlias, which were in extremely fine condition. Other plants were moderately well shown, but not in great numbers. Mr. H. Cannell, Swanley, Kent, contributed a large and representative collection of Dahlias. Show, Fancy, Bouquet, and single varieties were shown in admirable condition, many excellent forms being included. Some of the best Bouquet varieties were Perfection of Liliputians, very dark maroon; Nabob, purplish, neatly quilled; National, good scarlet; John Sandy, orange chrome tint; Sensation, pale yellow; Snowflake, white; Northern Light, rich scarlet; Lady Blanche, good white; Little Model, purplish crimson shaded; and Rigolette, dark maroon. In the Fancy varieties the following were noteworthy:—Regularity, pink with maroon streaks; Grand Duchess, chrome yellow, crimson streaks; Chang, pale primrose, fine maroon streaks; R. Burns, bright purple, darker streaks; and Florence Stark, white, crimson streaked. Among the Show varieties were H. Turner, handsome white; G. Smith, deep crimson; Victory, deep maroon; J. Keynes, rich yellow; H. Bond, fine bright purple; J. Bennett, good scarlet; and Amy Robsart, purplish puce, all fine varieties. Dahlia Juarezii was also very bright and good. Cultural commendations were awarded for these collections. Mr. Cannell also sent a plant of Iresine Wallisi of continental origin, somewhat in the way of Iresine Herbstii in the foliage and habit, but with the colour of I. Lindeni; it was very dwarf and compact. Messrs. James Carter & Co. exhibited several new Coleus that were not, however, deemed sufficiently distinct to merit an award.

Mr. J. Roberts, The Gardens, Gunnersbury Park, Acton, exhibited a group of dwarf Scabious in pots to show what useful plants they are for decorative purposes in autumn. They were singly in 24-size pots, and averaged about 18 inches in height, bearing a number of brightly coloured flower heads. Crimson, maroon, pink, white, and purple were represented. A cultural commendation was awarded. Mr. G. Fry, Further Green, Lewisham, sent a plant of the peculiar *Rubus australis*, or Australian Bramble, with trifoliate leaves, very slender petiole-like leaflets covered with small white spines. It bears in Australia the name of "Lawyers."

Messrs. Charles Lee & Son, Hammersmith, exhibited a fine collection of ornamental Oaks, including about sixty forms. Some of the most distinct and attractive were the following:—*Quercus cerris* elegantissima, prettily variegated; *Q. concolor*, pale yellow foliage; *Q. argentea picta*, pale green spotted and streaked with white; *Q. atropurpurea*, fine purple tint; *Q. pectinata*, neatly divided leaves; and *Q. filicifolia*, similar. Some variegated Elms and Chestnuts were also exhibited, all good. A vote of thanks was accorded for the group, and for a box of Tuberous Begonia blooms gathered from plants grown out of doors; they were especially noteworthy for their bright colours.

Mr. W. Iggulden, The Gardens, Orsett Hall, Romford, exhibited plants of an improved form of *Begonia semperflorens*, named *grandiflora*. It chiefly differed from the type in the larger size of the pure white flowers, the good trusses, and the freedom with which they are produced. It is likely to be very useful for cutting purposes, but the Committee desired to see it with the species and a variety of Messrs. Suttons'. Messrs. Keynes & Co., Salisbury, sent about nine dozen fine Dahlia blooms, both Show and Fancy varieties being well represented. Several good new varieties were certificated. Messrs. Rawlings, Bros., florists, Old Church, Romford, also exhibited several handsome seedling Dahlias; and Mr. G. P. Harris, Orpington, Kent, staged blooms of a beautiful yellow Show Dahlia named President, fairly good in form and of a most delicate pale yellow tint. Mr. Charles Noble, Bagshot, sent flowers of Rose Queen of the Bedders, of which it is stated flowers may be cut during five months of the year in the open ground. The Hon. and Rev. J. T. Boscawen, Tregothnan, Cornwall, sent flowers of *Bougainvillea glabra* gathered from plants growing outside unprotected. Sir H. W. Parker, Stawell House, Richmond (Mr. Howell), exhibited flowers of a very good variety of *Lapageria rosea*. Mr. H. Eckford, The Gardens, Sandywell Park, Cheltenham, was accorded a vote of thanks for a collection of seedling Coleuses, some of which were excellently coloured. From the Society's garden came fruits of the pretty *Fragaria indica*, so attractive either grown in pots or on the rockery, and flowers of the rich crimson *Canna iridiflora hybrida*.

First-class certificates were awarded for the following plants and flowers:—

Coleus Mrs. W. M. Shirreff (King).—A handsome and effective variety of good compact habit, with neat leaves, having a centre of rich bright crimson surrounded by a band of maroon, and with an evenly crenated green margin. Undoubtedly one of the best that has been exhibited.

Dahlia Walter N. Williams (Keynes).—This was certificated as a "decorative flower." It was chiefly notable for the extremely bright

scarlet colour and its great size, but was not of sufficiently good form to merit a certificate as a show variety.

Dahlia Joseph Green (Keynes).—A very good scarlet flower, described on page 254 in the report of the Brighton Show.

Dahlia Mr. Harris (Rawlings).—Excellent flower, good depth, rather hollow in centre but very regular in outline; colour deep rich crimson maroon.

Dahlia Frank Rawlings (Rawlings).—A handsome flower, very symmetrical, rather low in the centre, rich purple colour, very good depth.

Croton B. Franck Selliere (Chantrier, frères, France).—An extremely distinct variety, with leaves from a foot to 15 inches in length, 3 or 4 inches broad, very distinctly veined and variegated with yellowish white. It will probably form a fine exhibition plant.

THE SCOTCH CHAMPION POTATO.

MR. LUCKHURST seems to entertain anything but a favourable opinion of this Potato. I really cannot think he has the right variety, for with us last year its cropping, its keeping, and its cooking qualities were all that could be desired. The tubers when cooked were beautifully white and very mealy, with a good flavour—so much so, that I never had one complaint from the time we started to use them before Christmas last year until July this year. At that time being so good I had orders from London to send more of them, as those purchased there were not eatable. Surely this evidence is worth something as to the merits of this useful variety. True, it has one great drawback in its deep eye, but its other good qualities are so overwhelming that we almost, in our gratification, lose sight of this defect, for it has absolutely been a question of Champions or no Potatoes with us and other cultivators. That other fine variety *Magnum Bonum* until now has been too expensive to have been generally planted, but another year I hope to see it grown as largely as the Champion. I had always considered Mr. Luckhurst a very sober-minded writer, but in this case surely he has been a little precipitate. It is well to remember that both producers and consumers have a good opinion of the Champion, and it seems to be remarkable that Mr. Luckhurst fails to find even one qualification to recommend it. Your correspondent further states that we have plenty of varieties that possess all the good qualities of a Potato to supply us for eleven months of the year. I have tried most of the varieties introduced for the last twenty to thirty years, but up to the present time I do not know of one that I can depend on as possessing all the good qualities during the period named. For a main crop I find the two varieties above mentioned by far the most reliable. I have just been to the field and forked up a few roots of the Champion and *Magnum Bonum*, and really they are something to gladden one's sight, the tubers being large, numerous, sound, and clean. Paterson's *Victoria* growing by the side of them are a poor crop and much diseased—scarcely worth the labour of taking up. Last year our Paterson's were very bad; for every bushel we secured we had something like 19 bushels of Champions, and 12 or 14 of *Magnum Bonum*. The high approval I have adduced of the quality of the Champion will most certainly induce me to grow it extensively, unless Mr. Luckhurst can send me something better.—JOHN TAYLOR, *Hardwicke Grange, Shrewsbury*.

MR. LUCKHURST, on page 212, in reply to my note in the preceding issue, asks if he is to be "open to rebuke for refusing to cultivate a variety in which most of the points of excellence that a Potato should possess are conspicuous by their absence?" I reply, Certainly not. He is fully justified in discarding any variety that does not answer his expectations. But it is quite another thing to denounce the Scotch Champion for not being good in August. It cannot be good then. To my suggestion that the true variety was possibly not obtained "for trial," Mr. Luckhurst makes no reply, nor does he allude to the circumstance that the Champion was certificated for its good quality when cooked. I think it is a mistake either to overpraise or denounce any Potato that has not been subjected to a fair trial, and it is simply impossible for anyone to fairly prove the quality of the Scotch Champion in August. The true variety is not fit to eat then, but I have had it during the spring (when no other Potatoes were to be had) of excellent quality, and I think I know a good Potato, being—AN IRISHMAN.

I HAVE recently been through the four provinces of Ireland, and I am inclined to doubt that Champions in Ireland and England mean one and the same Potato, at least with some people. The Champion here is decidedly a very late Potato. Still, now approaching the middle of September, when many of the earlier kinds are wholly consumed, and the intermediate varieties in general use, it is quite green and growing freely. This is the case in the midland counties, every one of which I have been through

within the past fortnight, and it is still more so in Ulster. The observer can see the patches of Champion as he drives by at a considerable distance, while the haulms around of other varieties are long since withered. Visiting at Carlow, a typical eastern county, I examined stalks here and there and found the Potato, though not large, perfectly free from blight, and when well cooked—and I will recur to that point—of excellent quality, mealy, and dry. This was particularly the case when grown in a tolerably rich dry upland. A friend of mine had a quantity in a sandy moor, and these were not of such good table quality, but fine for seed, for which purpose they were grown. The stalks of those are still green. They were marked by blight spots on the leaves, but, unlike other varieties, the fungus appears to be unable to make any great progress in destroying the stalks or stems, I presume owing to their firm, fibrous, woody nature. So much for the east

of Ireland. Now for the west, which is of much more importance, as the people subsist to a much greater extent on the Potato crop, as they have no Wheat nor black Oats to depend on. There the peasantry were dependant on charitable aid in many cases, and their Champion Potato is later still; while leaving Sligo, Mayo, and Galway a week since they were still green, and in no case had been using for eating purposes. How can this be the same Champion referred to by Mr. Luckhurst and others, and that had been using in England a month since, and that your correspondents noted as being blighted before that time?—W. J. M., *Clonmel*.

AUGUSTE JURIE PEAR.

HAVING been certificated on August 24th by the Fruit Committee of the Royal Horticultural Society, this Pear demands

Fig. 53.—AUGUSTE JURIE PEAR.

further attention. The fruit as grown at Chiswick is above medium size, $3\frac{1}{2}$ inches long and $2\frac{1}{2}$ inches wide, obtuse ovate; skin green, becoming yellowish green as it ripens, with a thin speckled coat of russet on the side next the sun, and strewed all over with russet patches. Eye closed with tooth-like segments, and set even with the surface; stalk from 1 to $1\frac{1}{2}$ inch long, inserted without depression; flesh crisp, rather granular, sweet, briskly flavoured, and with a fine melon flavour. A valuable early Pear, ripe in the middle of August, and which is well worthy of general cultivation.

This Pear was raised at the Ecole d'Horticulture at Ecully, near Lyons, under the direction of our friend, the late M. Willemoz. It originated from seed of Beurré Giffard, sown on the 11th of August, 1851, and it was named in honour of M. Auguste Jurie, President of the Horticultural Society of the Rhone. The fruit as it is grown in this country varies very considerably from that grown in France. There it is shorter than with us; the

stalk is also shorter and the colour much brighter. Our friend Abbé Dupuy describes it as orange yellow and bright red on the side next the sun, and ripening in the end of July and beginning of August. It is thus that some of our countrymen make such mistakes in giving descriptions of fruits, which are mere translations from foreign works, and not made from the fruit itself as grown in this country. The fruit represented was grown in the Royal Horticultural Society's Gardens, where the tree grows well and bears freely as a pyramid.

PICTORIAL PERIODICALS.

REFERRING to coloured plates of flowers "AN ARTIST" writes: "These appear to be becoming a drug in the market. Once they were framed and cherished by gardeners, now they decorate tool sheds and such places, and appear to be very attractive to spiders, which veil them with their slender network. These plates are

nothing if not fair and honest representations of flowers. If overdone they deceive purchasers; if underdone they do an injustice to the flowers. Two remarkable examples of inaccurate flower delineation have just come under my notice. An imposing volume, 'Greenhouse Favourites,' published by Messrs. Groombridge, and a number of 'Paxton's Flower Garden,' issued by Messrs. Cassell, each contains a coloured plate of *Spiraea palmata*. Let anyone examine these two plates, and he will have a striking instance of the vagaries of art. The colour of the flower in one figure is lilac or pale washy purple with a few crimson blotches; in the other it is a dull heavy crimson, the flowers being shown in masses of ugly lumpishness. The two figures of the same plant are totally dissimilar, and neither of them does justice to a beautiful plant."

We have referred to the figures indicated, and are bound to admit that our correspondent has justification for his trenchant remarks; but we may remind him that the great number of inferior plates now published render those that are superior, and these are not few, of greater value.

We may now appropriately refer to the two works mentioned.

"PAXTON'S FLOWER GARDEN" (Cassell & Co).—On perusing the first number of the re-issue in parts of this work we regret to notice that the most characteristic representation that has yet appeared of *Spiraea palmata* is marred by faulty colouring; the plate of *Aërides crassifolium* is much better in this respect. The work is admirably printed on superior paper, and is revised by Mr. Thomas Baines, whose reputation as a plant-grower is a guarantee that the cultural instructions embodied in the work are reliable. But why capital initial letters are employed for specific names we are at a loss to understand. If a reform is being initiated it is in an opposite direction to the system adopted by all European botanists of repute, for the disposition of men of science and education is to reduce, not increase, the number of capital initial letters. We consider such letters as they are employed in "Paxton's Flower Garden" incongruous and a mistake; otherwise the republication of the work is timely, and if the two plates given monthly are of a superior character, each number will be cheap at a shilling. This work will not unlikely become very popular, and when completed will be a worthy addition to all gardeners' libraries.

"GREENHOUSE FAVOURITES" (Groombridge & Son).—This work requires little comment, as its merits were discussed in these columns when it was appearing in monthly parts. We need only remark that it makes a handsome and elaborately finished volume as regards binding, printing, and paper. Some of the coloured plates are also worthy of commendation, while others are unsatisfactory. The cultural particulars are generally correct, but in some instances they are of a tediously commonplace character, not quite in harmony with the ornate character of the volume. The lists of varieties are in respect of some genera very meagre, and those named are not in every case the best in cultivation at the present time, while curiously enough the chapter on Begonias does not include the most popular Tuberous section in which there are now so many grand varieties.

DRAINAGE—CULTIVATION OF THE SOIL AND MANURES.—No. 4.

THE preparation of manure is the next consideration. Through a press of general work the manure heap is often forgotten until it is actually wanted. Neglect in small matters often leads to disappointment. The manure from the stables is often taken, and the shorter portions shaken out for the purpose of making Mushroom beds, the long litter being left to decay; but when this is required for use considerable difficulty is experienced in separating that which is decayed from that which is not ready for use. To avoid this difficulty, and when the ground is frozen or too wet to allow of its being worked, men could be most usefully employed in turning and thoroughly shaking out every portion of this litter and placing it into a good-sized heap, and throwing the drainings from the stables, &c., over the whole as the work proceeds. Repeat this at intervals of a fortnight or so for about six weeks, and then allow it to remain untouched for about the same time, when it will be found in a fitting condition to be taken to the garden for general purposes. Manure in a more decomposed state would be preferable for some crops, but in a general way it is not desirable to allow it to become too decayed.

We must now turn our attention to the refuse heaps. I write "heaps," because there should be at least two of these. The one should consist of all vegetable refuse, weeds, and anything that will decay readily. Anything that will not decay in a short time should be placed by itself; and when dry enough, and in sufficient quantity, fire should be applied and the whole covered with the surrounding soil and left to burn out, a little attention daily only

being necessary to cover any portions that have been burnt through. This charred heap will be found most valuable for the garden, also for mixing with the soil for potting purposes. The vegetable refuse, &c., having been taken to a heap by itself, as labour can be spared it should be turned, and as the work proceeds a sprinkling of salt and a good dusting of quicklime added, which will kill slugs and other insects. If the whole is placed into a good-sized mound it will ferment considerably, which will destroy the germinating powers of any seeds from weeds. This should remain for some time and again be turned, this time putting the outside into the centre and *vice versa*. If this treatment can be repeated two or three times during the winter months the refuse can again be taken back to the garden, and will prove most acceptable food to succeeding crops.

It will take several years in a large garden to do as I have advised in these papers; but in conclusion I would say, If only a small portion can be done at a time, let it be done thoroughly, bearing in mind the old and true saying—"What is worth doing at all is worth doing well."—ROBERT D. LONG.

MEALY BUG.

YOUR correspondent Mr. Bardney on page 208 asks me if bug is in the drainage of a vinery how would I destroy it? I should recommend as follows, and it would help to improve the crop of the Grapes in quantity and quality.

I should mulch the border well and keep the soil moist, as in the growing season Vines are rarely injured by too much moisture. More injury is done by having the borders too dry. Unless mealy bug is destroyed in one season very little progress can be expected, though the insects can be kept in check. The best plan for eradication is in the spring, after the house has been well washed and the Vines painted in the usual way, to search everywhere about the period the Vines are breaking. I believe the house has much to do with the ease or difficulty that would be experienced in dealing with the pest.

A friend who also is fortunate in having no bug was once inclined to argue with me that it would not breed in his houses, which are low and moist, but it would be certainly dangerous to give it a chance on his Stephanotis. In houses that are dry and much exposed to the sun mealy bug would breed more rapidly than if they were more humid and cooler. It might be interesting to your readers if anyone can report entire freedom from brown scale. Years ago I had Peach trees affected with it, but this is exceptional. I, however, do not recollect ever seeing a plant stove without brown scale. I have proved that paraffin is very dangerous in the hands of the inexperienced for even a hard-wooded tree. I should be disposed to say in regard to paraffin as an application for destroying any vermin on fruit trees—Beware! —R. M.

ST. FAGAN'S CASTLE.

THE traveller on the South Wales Coast line, on his way from Cardiff to Neath and Swansea, will—about three miles from the former town, and on emerging from a wooded gorge through which the river Ely flows from the picturesque vale of Glamorgan—have his attention attracted to a many-gabled mansion of unpretentious style standing on an eminence to the right not far from the railway. This is St. Fagan's Castle, one of the seats of Lord Windsor, who recently attained his majority. The mansion, which has still some remains of the castellated style, stands in friendly contiguity to the parish church (a plain-looking edifice dedicated to the saint whose name it bears), and to the village with its many thatched cottages spreading round two sides of it for some distance. The village has a neat appearance; it is healthy and clean, has a good schoolhouse and a comfortable inn. St. Fagan's is celebrated in the history of this country for a meeting held in the old village between King Charles I. and the leaders of the men of Glamorgan, and for a sanguinary engagement fought in the vicinity during the protectorate of Oliver Cromwell.

Lord Windsor owns 1700 acres of land in this district of South Wales, extending from St. Fagan's to Caerphilly, besides the ground on which stands the town of Penarth, with its docks, at the mouth of the river Ely, four miles south-west from Cardiff. Penarth is becoming a fashionable place for well-to-do people, and a great many costly villas have been built in it within the last few years. His lordship, besides other improvements, has made a handsome promenade along the margin of the beach for some considerable distance, which is tastefully laid out, and planted on either side with ornamental trees and shrubs. He has also had trees planted near the footpaths of all the roads and streets, and we learn he is going to lay out a public park for the people on a beautiful site.

The pleasure ground attached to the Castle of St. Fagan's is not of great extent, but it has been planned in a way to afford within a limited compass considerable variety of attraction. One feature of special interest and beauty is a series of four small ponds formed on a succession of terraces at the side of the plateau on which the Castle and gardens stand. The ground slopes both southward from the front of the Castle and westward, and advantage has been skilfully taken of the lower portion of the latter slope to form the ponds, which have a very ornamental and refreshing character when seen from the terrace above. The ponds are fed by a natural spring, which forms a small brook, having its start 200 or 300 yards from the upper lakelet. The clear water winds its way over bold pieces of rockwork, forming cascades till it enters the first pond. Thereafter it makes its way from pond to pond over the green banks which separate them by a succession of miniature waterfalls, till at the last it is carried by a stream to the river Ely in the valley below. On the side furthest from the Castle these little sheets of water are bordered by a line of Western Plane trees, and on the rising ground above them are some finely-grown specimens of Conifera and other trees, and a large maze, the hedges of which are formed of different varieties of Conifera, neatly clipped and kept in good order. In the centre of the maze are two fine Wellingtonias more than 40 feet high, the trunks of which 3 feet from the ground measure respectively 9 feet 7 inches and 9 feet 2 inches in circumference. On the side of the ponds next to the Castle they are bordered by grass terraces with flights of stone steps leading to the plateau above, the terraces being separated from the kitchen gardens by a broad gravel walk and wall. Fig trees and Vines are trained on the wall, and the border between the wall and gravel walk is tastefully planted with flowering shrubs. The ponds contain trout and other fish, and we understand Lord Windsor entertains some idea of using them for experimenting on the artificial breeding of salmon, or stocking them wholly with trout.

The gardens, which immediately adjoin the Castle on the west side, are not extensive, but are well arranged and laid out so as to give the maximum of effect, and of utility for the growth of fruits, flowers, and vegetables. The fruit and vegetable departments are separated from the Castle by a neatly laid-out geometrical flower garden, with fountain in centre and broad gravel outer walks, and beyond this a small bowling green. A gravel walk and Arbor-Vitæ hedge, with herbaceous border in front, encloses this portion of the gardens, which is in keeping with the style of the mansion. The other portions of the gardens are devoted principally to the growth of fruit and vegetables. The soil is good in some places but shallow, not exceeding 2 feet in depth, resting on a subsoil of rotten rock; no drainage, therefore, is required, and the soil can be worked in a few hours after the heaviest rainfall.

Mr. Crossling, his lordship's gardener, has improved the quality of the soil very much within the last few years by removing a portion of the subsoil annually and adding fresh soil to it from old pastures in the neighbourhood. Fruit trees are well managed at St. Fagan's. Apricots, Peaches, Nectarines, and Plums do well on the walls. Mr. Crossling pays great attention to them, and the result of this is fine crops in ordinary seasons. Apples and Pears with a few exceptions are a failure here, as in other places this season. Morello Cherries on a north wall were good, and small fruits most abundant, except Raspberries, which were nearly killed to the ground last winter owing to the canes having failed to ripen properly. The soil and situation seems to be well suited to the growth of Strawberries. We never remember having seen a better crop of President, or healthier plants than we saw here. The plants were literally covered with large fruit of the very best quality. Vegetables were abundant and good, and the gardens throughout thoroughly cropped and in first-rate order.

In a space of ground to the west of the kitchen gardens, which was wont to be covered with old Pine pits and other buildings, Mr. Crossling has recently established a rosery, retaining of the old erections only the enclosure walls. Here are to be found a fine collection of the choicest Roses, neatly arranged in narrow beds, with grass walks between, so as to afford a most pleasant means of minutely inspecting each bloom as it opens. The south portion of the enclosure wall was planted with Camellias a few years since, but they have not succeeded satisfactorily, and it has been planted with Tea Roses, which grow luxuriantly and flower freely. On the west side, abutting on the rosery, is a very useful storehouse for keeping large Sweet Bays and other plants in winter, which are placed on the terraces in the summer months. In front of this are some of the finest trees of Evergreen Oak that are to be found in South Wales—noble specimens in robust health, with straight clean trunks without a branch for a considerable distance, terminating in fine evenly-balanced heads.

The glass is limited in proportion to the size of the place. It consists of a vinery and Melon house in one range, and a greenhouse with pits in front in another. Besides this, there is a Melon ground with pits, frames, &c. The vinery is filled from end to end with one Black Hamburgh Vine, which is planted in a border outside. It enters the house in front at the centre. Two main rods are led horizontally along the top of the front sashes to either end, and the fruiting canes from them are trained at regular distances to the top of the trellis. For the sake of variety Mr. Crossling has inarched a Buckland Sweetwater Grape at one end, and a Gros Colman at the other. The Vine (like the place generally) has been much improved within the last few years, and this season it is bearing a crop of Grapes which would be difficult to surpass, taken as a whole, for size of bunch, berry, and finish, even with a house of Vines much younger treated on the restriction system with a Vine to each rafter.

In the house adjoining was a fine crop of Melons. Here they are treated liberally, and the fruit was large and well netted. One end of the house was planted with Tomatoes trained on single stems close to the glass. Mr. Crossling pays great attention to the culture of this fashionable fruit (what else is it?) both in and out of doors. He has tried many varieties this season with the view of testing their respective merits, but has failed to find one of them to equal his own variety (Glamorgan), which was raised by him a few years ago. It has something the appearance of Trophy, but the fruit is much larger, the plant more prolific, and the habit is quite different to any variety that we know.

The earlier occupants of the greenhouse were mostly placed out of doors at the time of our visit, and the house was filled with neatly grown Zonal Pelargoniums and other plants for table decoration, and on the back wall were some fine healthy Tomatoes for late use. In the Melon ground, which is well sheltered, having a fine southerly exposure, were good crops of Melons and Cucumbers growing in pits and frames.

In conclusion we would say that all departments of this charming place are carried on with care, intelligence, and success. Mr. Crossling is entitled to no small credit, not merely for the neat way in which the grounds are kept, but for the splendid specimens of vegetables, fruits, and flowers he produces, as has been certified by the prize lists of some of the best shows in the west of England.—RESEDA.

THE EFFECTS OF ELECTRICITY ON VEGETATION.

A FEW years ago a remarkable occurrence in connection with injury to vegetation led to a discovery which not only explains most fully and clearly the occasional deleterious effects to plants trained upon galvanised iron wire, but at the same time it has thrown some light upon the laws of growth and disease, and serves to elucidate a class of phenomena which had been previously altogether incomprehensible.

A large plant case on a bronzed stand, purchased from one of the first houses in London, and planted with Ferns by Mr. Kennedy, late of Covent Garden Market, was taken to Queen Anne Street, Cavendish Square, and placed in a situation in every way favourable to the Ferns, but, strange to say, instead of their flourishing or even continuing in a fairly healthy condition, they all died. Attributing this, as one would naturally, to mismanagement, the case was cleaned and replenished, but only to experience a similar disappointment. It then became evident that some unusual condition must pertain to the case itself serving to effect this destruction, and on closer examination this was discovered. The case and framework being constructed of zinc and the bronzed table of cast iron, neither the under surface of the former nor the upper surface of the latter having been painted, the two metals were in contact, and hence a galvanic action was set up between them.

Now as the uninitiated reader may be sceptical as to any possible influence to any practical extent from the mere contact of two dissimilar metals, let him place the end of a zinc tally upon the tip of his tongue, and one bow of a pair of common scissors under the tongue, and then bring the other bow to touch the zinc so that the two metals touch each other at one end at the same time that the moist tongue touches the two metals at the other end. At the moment of bringing them together a peculiar saltish metallic taste will be experienced and repeated every time the metals are separated and brought together again. But now substitute a piece of silver—a half-crown, for the iron of the scissors under the tongue, and a much more perceptible effect will be produced. Such, then, being the effect of the contact of the zinc case with its iron stand, the obvious remedy was to separate them by the insertion of insulating strips of wooden laths. This was immediately had recourse to, and in a very few hours the plants, losing

this galvanic influence, had assumed quite a different appearance, and soon acquired a healthy luxuriance. Doubts being expressed whether it were possible that such apparently insignificant means could have alone been the cause of the mischief, and nothing short of ocular evidence being convincing, the wooden laths were removed, and the case full of healthy Ferns was thus again subjected to the galvanic action as it had been originally. On the following morning, or after about twenty-four hours, the plants were dull and drooping, mildew had appeared, and the case looked unnaturally moist. The next twenty-four hours, however, brought matters to a crisis. Fronds were decaying and had become covered with fungoid growths, festooning from one to another like cobwebs; whilst the whole interior, both plants and soil, emitted most powerfully the peculiar Mushroom odour, and in addition to which various minute fungi had sprung up in the vegetable remains constituting the soil below. This evidence having been accepted as sufficiently conclusive, the laths were replaced so as to destroy the galvanic action and render the case innocuous as before. On examining it some few hours afterwards the change that had taken place created no little astonishment. Hardly a trace of the former cobwebby appearance was to be seen; all the fungi had been dried up and had disappeared, and the atmosphere within had become clear and dry.

It is now evident that galvanised wire, having an external surface of zinc, when fastened with iron nails must inevitably be equally galvanic in its effects, yet when the fastenings are galvanised too the whole is rendered perfectly innocuous like the insulated plant case. It is only when dissimilar metals are in contact with each other that the wire becomes hurtful. But in order to establish more fully the identity of these phenomena with electricity, a small battery was so arranged that the two separate conditions should be going on simultaneously. A portion of Cress seed was spread thinly on a piece of thick wet flannel placed on a piece of glass, and the two terminal wires from the battery were made to rest upon it some little distance apart, so that the communication of one with the other was left to be completed by the moisture; consequently these wires represented respectively the zinc and the iron, and were anticipated to produce the same corresponding results, as they unquestionably did. The first signs of growth took place amongst those seeds surrounding the wire representing the zinc or positive end. They, however, made very little progress, but soon died and became blackened, and ultimately tenanted by the mycelium of a fungus. At the opposite or negative end the seeds were longer in germinating, but they became greatly swollen and retained their full brightness, ultimately acquiring a healthy and luxuriant growth, which they maintained so long as the action was kept up.

These very significant features demonstrate the highly important fact that under one condition of electricity plants are killed but fungi flourish, whilst under the opposite condition fungi are destroyed and plants luxuriate. As, however, the direct application of electricity on a useful scale is quite beyond the limit of practicability, it is hence very fortunate that electrical attraction and chemical affinity are similar. We are enabled to accomplish the same ends by having recourse to chemical appliances. Liebig in one of his writings states that "we know nothing whatever of the chemical changes taking place at the surface of the earth," which was unquestionably true at that time, but happily does not apply to the present time. The preceding facts, in conjunction with others belonging to the same class, serve to elucidate these proceedings in the most unmistakable manner. One of the first lessons derivable from these views is that manures may be separated into two opposite divisions—one corresponding with the zinc, and the other with the iron, as above. The distinctive feature of these divisions is that one supplies oxygenated food to the plants, while the other is wholly devoid of oxygen, and leads to the production of mildew and other fungi. Ammonia consists of only hydrogen and nitrogen without a particle of oxygen save in the water in which it is dissolved, hence it cannot possibly afford any oxygenated nourishment to the plants through its roots, and therefore we must look for some other direction for its effects. On the other hand, all those substances which redden blue litmus paper owe this property to the presence of oxygen, and these have been found by experiment to be readily absorbed by roots, whilst ammoniacal solutions in their alkaline state are rejected. These results have been verified practically on a very fairly extensive scale. An old vineyard, 30 feet long and containing eight Vines, had become so infested with mildew as to be worse than useless, and the opinion of one of the oldest and most successful Grape-growers of the district was that the only chance of rectification would be by cutting down and re-grafting. Coupled with this the head gardener suggested that unless the border were to be dug-up and

remade he thought the other would be of little or no use. The advice of neither, however, was accepted. The circumstance was deemed too valuable in connection with these means to be lost. Having witnessed under what conditions mildew originated and how it was exterminated by an opposite treatment, this was carried out on the same principle, and the result was, that in the following season a very fair crop of Grapes was obtained, which coloured most satisfactorily, whilst not a trace of mildew was to be found in the whole house. Now this mildewed condition had been brought about by the excessive use of stale night soil, the ammonia of which had done the mischief; therefore, as a test trial, one of the end Vines was liberally supplied with a solution of guano, and on the following morning spots of mildew were traceable all over that Vine, leaving no doubt as to its origin. Tea and other Roses have been treated with equal success, and therefore there is reason to hope that this pest may soon become a thing of the past.

In the above-recorded experiment with Cress seed it was observed that those seeds around the positive or oxygen-attracting end of the battery were not only killed, but their husks were blackened like a piece of half-burnt wood. The like of this may be witnessed in almost every garden. Stems and branches of trees and plants trained in contact with rusty iron, such as stakes and trellises, or fastened with iron hooks or nails to walls or fences, are killed precisely in the same manner. Hence, although oxygen is so essential to the roots of plants, it is destructive to their leaves and stems. These experiments teach us the true use and action of oxygen in life, and prove it to be very different from what has hitherto been suspected; but as it forms one of the chief agents in growth it is of too much importance to be dragged in at the end of a chapter, and therefore (with the Editors' permission) it will be better that it should be treated more fully in a separate communication.—W. K. BRIDGMAN, *Norwich*.

CHAPTERS ON INSECTS FOR GARDENERS.—No. 11. NEW SERIES.

WHEN considering in a methodical manner the well-nigh innumerable host of species that are placed in the class Insects, we may go either from the higher to the lower types, or from the lower to the higher. Having pursued in these articles the latter plan, and started with the humble wingless insects, such as the

Fig. 54.—Larva of Tiger Beetle and its tunnel.

fleas, of the order Aptera, we now reach, in conclusion, the order Coleoptera, which is by general agreement of naturalists regarded as the highest in structure amongst the orders. Beautiful in colour and marking as are many of the butterflies and moths, several circumstances, especially their possession of a sucking mouth instead of jaws for biting, put them below the rank of the beetles and other insects less attractive in appearance than the gilded flies that disport in the sunbeams, or the less showy yet often richly-tinted moths that haunt the evening shades. Another thing that is notable about the order of the beetles is that it surpasses all the rest in the vast array of distinct species that have already been recognised or suspected. Probably at least fifty thousand are contained in collections, and every year is adding more as travellers penetrate new regions. Even these small islands of ours present us with about three thousand species; only a few of these, however, it is pleasant to know, do injury to our fields or gardens, though these species are at times both numerous and active.

It is only necessary to mention some of the beetles that are noticeable on cultivated ground to show how great is the variety of size and form observable amongst the Coleoptera. We may name as illustrations of the order such species as the cockchafer, the Rose beetle; the skipjack, the larvæ of which is the wireworm,

pre-eminent amongst several larvæ so named; the Pea and the Pear weevil, instances out of a group of garden infesters; the Asparagus beetle, the cocktail, and the ladybird. Beetles there are that have not been so designated in popular phrase, like the Turnip flea (*Haltica nemorum*), one of the many species that are able to leap and skip as well as walk or fly; and other insects, of which the cockroach (*Blatta orientalis*) is a well-known instance, are called beetles, though really belonging to decidedly different groups. To the word "beetle," it might be added, belongs a fragment of antique history, for some think our Saxon ancestors thus named certain insects because of their hard or tough exterior; but it is more probable that *bitl*, its first form, came from *betan*, to bite, suggested by the destructive operations of the insects as seen in the fields or woods.

Coleoptera have, however, taken their scientific name from the fact that the fore wings are horny and leathery, covering the hind wings entirely in most species when the insect is not in flight. These fore wings do not help a beetle when it is in the air, except so far as they may steady its movements; the whole work of flying is performed by the hind pair, which are large, and contain strong nervures. A few beetles are incapable of flight, and some of the water beetles, though able to fly, seldom take excursions in the air. The mouth of a beetle when examined shows the usual upper and lower lip, of a horny nature in this order, a formidable pair of jaws or mandibles, and a second and more delicately constructed second pair below the first, which are called maxillæ, and furnished with two feelers or palpi. The legs of beetles in their jointing give important characters, by which groups are distinguished, as also do the antennæ, which are sometimes thread-like, sometimes knobbed, sometimes resembling a saw, a comb, or a fan, or a necklace, and other variations. Occasionally the shape of the antennæ is associated with certain habits; thus most of the beetles with slender antennæ prey upon living insects.

Anyone who has picked up, as most probably have, a specimen of that frequent visitant to gardens at dusk, the dor or watchman beetle, must have discovered that this beetle has a remarkable strength of muscle for its size. M. Plateau experimented with an apparatus so contrived as to test how much a beetle could pull along. While one of the ground beetles could draw seven times its own weight a cockchafer could draw fifteen times, and the species called *Trichius fasciatus* about forty times. The larvæ of beetles, familiarly known by the vague term "grub," are also muscular in body and limb, usually six-footed, though a few almost lack these useful appendages. Some are feeders in prominent positions upon animal and vegetable substances, but in the general way beetle larvæ prefer to conceal themselves, hence it happens that many common species are unknown in their early stages of life. The pupa state is passed in quiescence, and the outline of the future imago is traceable more or less clearly on the exterior of the pupa skin. It is not requisite that we should enter here into minute particulars about those divisions amongst the beetles which serve for scientific classification; but every gardener ought to know the distinctions which separate the principal tribes from each other as a help towards the recognition of individual species that may be hostile, favourable, or neutral. Speaking broadly, we might say that mankind derive a number of benefits from the race of beetles that overbalance the injuries done by some, and in the narrower range of horticulture it is almost probable though not proveable that our beetle friends and foes are about on an equality with each other. Thus we start, when taking a closer survey of the Coleoptera, with the tribe or section of the Adephaga, which have long slender antennæ, and maxillæ furnished with two palpi or feelers. These are all predacious, and again divided into land and water beetles, one having the legs formed for running, the other for swimming. The tiger beetles of the first genus *Cicindela* are of elegant shape and bright colours; it is their habit to expose themselves to view fearlessly during daylight. *C. campestris*, the common tiger beetle or "sparkler" (fig. 54), is frequent on sandy banks and heaths in the summer, and is occasionally seen in gardens. They kill numerous insects less than themselves, or even larger; the larvæ also live upon various "small fry," which they catch by means of a tunnel excavated to at least the depth of a foot. The earth that has to be removed is carried out by the larva in loads, which are dexterously rested upon the broad flat head. Instead of lurking at the bottom of its tunnel, as does the larva of the ant-lion, the larva of a tiger beetle lodges itself just below the mouth by means of a hump upon the back which has two curved hooks. When some insect slips into the opening the larva rushes forward, and seizing its prey glides down with it to the end of the burrow, where the capture can be eaten up at its leisure. Supposing a colony of these larvæ could be established in a garden they might be of some use in destroying insects. Their habit, however, leads

them to prefer open and sandy places, though one species, *C. sylvatica*, is presumed to have a liking for woods. The larva life in these, as in many beetles, endures much longer than that of the perfect insect.

Some beetles belonging to this tribe exemplify the fact, that an erroneous idea concerning the habits of an insect is apt to be formed owing to the circumstances under which it is found. We have nine British species of the genus *Dromius*, small beetles with slim flattened bodies, and which, though occasionally seen under stones, are usually resident under the bark of trees. Hence it has been imagined that they perforate the bark or wood, which is not the case, their object in life being to devour various insects that hide between the bark and wood, from whose proceedings mischief actually does arise. But when clearing off loosened bark from the trees that have been attacked by insects, it is difficult to separate the species that may be brought to light. *Clivina fossor* is an instance of a predacious beetle that deposits its eggs upon rotten wood, in which the larvæ construct burrows. The beetle varies much in colour, being black, brown, or red, and the darker specimens are those, it is noticed, that live partly exposed, as amongst heaps of decaying leaves.—J. R. S. C.

HARDY FRUIT GARDEN.

LITTLE requires to be done in this department at the present time except attending carefully to ripening fruit. Trees against walls should be examined every morning when the dew is off, and all Peaches, Nectarines, Plums, Figs, &c., should be removed as soon as ripe, and their flavour is improved by keeping them a few days on shelves in a well-ventilated fruit room. Fruit that is to remain upon the trees for some time longer—such as Morello Cherries, Coe's Golden Drop Plum, and other late varieties—must be protected against wasps by hexagon netting. The finer varieties of Plums may be enclosed in muslin bags, and Peaches, Nectarines, and Figs may be secured by similar means. Gather the early Apples and Pears as they become ripe, placing them carefully on shelves in the fruit room. Considerable judgment is requisite in gathering the fruit, for if taken too soon they will shrivel; and if allowed to remain too long upon the trees the flavour is deteriorated, besides not keeping so long or well, which also occurs when the fruit is bruised or injured. Examine all espalier, cordon, bush, and pyramid fruit trees, as well as trees against walls, and remove unnecessary shoots, nailing or tying-in the growths, so as to afford the young wood and spurs the full influence of sun and air. Autumnal Raspberries will soon begin to ripen their fruit, and will require to be carefully protected from birds. This crop in most establishments is exceedingly useful, and it is surprising that they are not more generally grown. The plantation should be formed in an open situation, the ground liberally enriched, and as soon as the crop is gathered the canes should all be cut down close to the surface of the soil. In the spring carefully select from four to six of the strongest canes to each stool, cutting away the others. Strawberry plants that were turned out of pots after being forced will be about setting an autumn crop, and the fruit will soon require the protection of nets; and if span-roofed frames are available they may be placed over the plants, air being freely admitted, and this will improve the quality of the fruit. Plants that have been retained in pots for autumn fruiting should, as soon as the fruit is fairly set, be transferred to frames or positions near the glass in a light well-ventilated house to ripen the fruit, whilst later batches should be moved to frames or houses, and have air freely night and day until the fruit is set; but it swells better in a rather closer atmosphere and a temperature of 55° to 65° artificially, and as the fruit changes colour a lessened supply of water at the roots with a drier atmosphere will be necessary to secure flavour.

FRUIT HOUSES.

Melons.—Plants swelling their fruit will require considerable attention to guard against canker. The remedy that has been frequently pointed out is freshly slaked lime pressed well into the affected parts,

repeating the application as may be necessary. Cracked fruits will need to be guarded against by the reduction of the moisture both at the roots and in the atmosphere. The temperature should be maintained at 70° to 75° by day artificially, which may fall to 65° in the morning. The house will need damping morning and afternoon where crops are swelling off, but only on very bright days must the syringe be employed over the foliage, and that early in the afternoon. Earth-up the roots of the last batch directly the fruit commences swelling. Plants in frames and pits must be sparingly watered, and when necessary afford it early so as to have the foliage dry before nightfall. Renovate the linings to finish off the crop directly the heat is found to be waning, and employ a covering over the lights on cold nights.

Cucumbers.—The temperature should be maintained at 65° minimum and 75° maximum from fire heat, with a rise of 10° to 15° with sun heat. Remove unhealthy leaves and old growths, stopping and training the others as necessary. Employ the syringe sparingly, only damping the foliage on bright days so that the foliage may become dry before nightfall. Damping will require to be done in the morning and again in the evening. Continue the preparation of fermenting materials whether tan or dung; the former will only require to be turned over once, but the latter will need to be turned over about every fourth day as soon as warmed through. Pot off seedlings as they become fit, and keep them near the glass to ensure sturdy growth, pinching out the growing points at the second rough leaf. Be sparing with moisture to plants in pits and frames, maintaining the temperature above indicated by renovating the linings, and employing a covering of mats over the lights on cold nights and closing early.

Pines.—Young plants that have been liberally and properly treated show at this season luxuriant growth, and as the influences inducing this state of the plants are decreasing both in force and duration it will be necessary to take steps to prevent the growth becoming soft and attenuated. A drier atmosphere about the plants should be maintained to consolidate the growth, employing fire heat when unfavourable weather prevails. Syringe occasionally early in the afternoon on sunny days. When water at the roots is necessary give a plentiful supply of weak liquid manure at the same temperature as the bed; keep the bottom heat steady between 80° and 90°; attend well to the ventilation, closing the house at a temperature of 80°, maintaining the night temperature at 65°. Encourage plants on which the fruit is swelling with heat and moisture, the night temperature ranging from 70° to 75°, and in the daytime from 80° to 90°, closing the house at 85°. Plants for starting into fruit early in the ensuing year should be selected from those which were started last March, and be brought together about the end of the month where they can be rested for about six weeks.

FLOWER GARDEN.

With shortening days and genial night dews grass is growing fast, and will require frequent mowing and rolling to secure a good solid greensward for the winter. Weeds on gravel walks also grow freely in late summer and autumn, and should be eradicated even if the walks have to be broken up. Hand-weeding may be saved by watering with salt water, the surface having a good sprinkling during sunny days, which will not only destroy weeds but will check worms from casting up and disfiguring the surface. The leaves of deciduous trees in some instances—notably Beech, Sycamore, and Lime—are already falling, and should be swept up frequently. Pick off all decayed flowers and foliage as soon as perceived, keeping the surroundings as well as the beds as trim as possible. All propagation to be finished excepting *Violas* and *Calceolarias*, for which there is ample time, all cuttings being closely watched to prevent damping, and expose them fully on fine days to thoroughly harden them for successful wintering.

The bulb season has begun, and these should be procured at once, not only to ensure good bulbs, but to have them in readiness for planting directly the ground becomes vacant. For borders there are many that should be planted now, as the border *Narcissus*, which are among the most useful and beautiful of spring-flowering bulbs; some of the best of which are *maximus*, *nobilis*, *cernuus* and *var. pleno*, *bicolor* and *vars. Horsfieldi* and *Empress*, *moschatus*, *rugilobus*,

Incomparabilis vars. alba, *flore-pleno*, *Stella*, *aurantiacus plenus*, and *sulphureus plenus*, *biflorus*, *poeticus*, and *vars. angustifolius*, *ornatus*, and *flore-pleno*. The common varieties should be planted extensively in shrubbery borders, &c., such as *N. pseudo-Narcissus* (*Lent Lily*), *N. Telemonius plenus* (*Double Daffodil*), *major* (*Trumpet major*), *N. incomparabilis vars.*, and *N. poeticus vars.* Jonquils also do well in borders, particularly *Campernelle*. It is hardly possible to have too many of such plants as *Snowdrops*, *Winter Aconite*, *Scillas*, *Muscari*, *Crocuses*, *Anemones*, *Tritcleias*, &c., all of which should be planted with as little delay as possible. Hyacinths and Tulips are indispensable for a display in beds, and are equally valuable for mixed borders. Roses will be better for having the dead flowers cut off and long sappy growths shortened, to ensure the plumping of the buds at the base, but not so closely as to start the buds into growth that the shoots will need to be pruned to in winter for next season's flowering, otherwise that will be destroyed. The stocks recently budded should be examined, loosening or removing the ligatures as required. Cuttings of well-ripened wood strike readily inserted in sandy soil on a north border. Annuals may still be sown in patches where the plants are intended to flower, thinning them out when large enough. *Anemone japonica* and *var. alba* are now fine, the latter especially, also *Sedum Telephium purpureum*. Phloxes make a grand display. *Senecio pulcher* (very fine), *Sedum spectabile*, *Veronica spicata*, *Polygonum vacciniifolium*, *Tritomas*, *Spiræa Filipendula*, *Hypericum calycinum*, *Hyacinthus candicans*, and *Fuchsias* are all beautiful.

PLANT HOUSES.

Greenhouse.—Hardwooded plants must be at once placed into their winter quarters. The weather lately being favourable to the ripening of the wood will have induced a free disposition to flower, and the wood will be in good condition for resisting mildew. Every plant, however, before being taken indoors must be examined, and if the least trace of mildew exists it must be destroyed, or it will spread with amazing rapidity when the plants are taken indoors. Dusting with sulphur is an effectual remedy, the plants being laid on their sides and syringed, and whilst wet apply the sulphur, the plants being allowed to remain on their sides until dry, when the sulphur should be thoroughly washed off and the plants still continued on their sides until the plants are dry, for on no account must the sulphur be allowed to pass into the soil. Plants that have the soft leaves and make growth in the winter should be given the lightest positions, such as *Boronias*, *Gompholobiums*, *Pimeleas*, *Tremandras*, and *Phœnocomas*. If Heaths have to be wintered in the same house they should be kept at the coolest end, and by ventilating more freely at that part they may be managed, but a separate house is much better for them. The general stock of hardwooded plants will require the night temperature kept at 35° to 40°, but *Leschenaultias*, *Aphellexises*, and a few others must not have the night temperature lower than 40° to 45°. Heaths that require more root room may now be repotted, proportioning the shift to the character of the plants and the condition of the roots. Free-growing kinds that have been in 12-inch pots and have plenty of active roots will bear a shift into 15 or 16-inch pots, but it is not safe to give large shifts to very hardwooded kinds, as they produce roots slowly. See that the ball in each case is thoroughly moist before potting. After potting place the plants in a house where the side lights can be kept closed for about three weeks, and a sufficiency of air given by the roof lights.

Camellias.—The plants if they have been placed outdoors should be taken in before there is danger of frost or drenching rains, which causes loss of roots or the buds to drop. The thorough cleaning of the foliage will be of advantage to the plants, and if the plants are infested with scale it must be removed with a brush and sponge. Plants that flowered early and were well attended afterwards would set the buds early and will now be well advanced; they will flower freely in a house kept a little warmer than an ordinary greenhouse, but there must not be any attempt at forcing them, or the flowers will in all probability fall before opening. To accelerate flowering increased temperature and a little more moisture are all that are needed.

Azaleas.—Plants that flowered early or were forced will now have matured the buds. If the plants are wanted to flower early again they should not be retained too long, but be moved to a house where

they will have a temperature of 40° to 45° at night and 50° in the day, so that they will come on with little forcing. For forcing the early varieties should be employed, such as Borsig, Narcissiflora, Raphael, all three with double white sweet-scented flowers; Fielder's White, alba, vittata elegans, and Jean Vervaine, one of the freest and best of Azaleas, which are all valuable for affording cut flowers, and for decoration. The later-flowering plants must not be shaded any longer, and they should at once be tied into shape before the growth is complete, so that the points of the shoots may assume their upright position.

Chrysanthemums should have the final staking and training, the upright bush form being most suitable for general purposes. Employ no more stakes than are necessary to keep the plants in shape. Where large flowers are wanted the side growths must be removed from the principal shoots, retaining the latter in numbers proportionate to the size of flowers required, retaining a single flower to each shoot, removing the flowers not required as soon as they are large enough to cut out with a pair of scissors. Plants trained with single stems for specimen blooms must also have the side growths removed, and all flower buds except the central one. Afford liquid manure liberally. Pot the chief batch of Hyacinths, Narcissuses, Tulips, Crocuses, &c., plunging the pots in a good bed of ashes 6 inches below the surface, and if there is convenience for throwing off heavy rains it will be an advantage.

TRADE CATALOGUES RECEIVED.

James Yates, Stockport.—*Catalogue of Bulbs.*

*** All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

The Growth of Beans (*J. H.*).—There is no foundation whatever for the absurd story to which you refer, and it is surprising that such singular notions can be entertained now-a-days.

Wall Trees (*Ramallo*).—All kinds of fruit trees that will succeed against a brick or stone wall in your district, will also succeed against a flint wall of the same aspect. Peaches and Nectarines would no doubt thrive well, as also would Pears; but the wall is too low for growing fruit trees satisfactorily.

Vine Wood Injured (*Fleetwood*).—We shall be glad to receive some leaves of the infected Vines, which we think will aid us in determining the cause of the peculiar substance growing on the bark. Please send us a fair sample, say half a dozen leaves, not selecting those that appear the most healthy.

Bulbous Irises (*E. S. W.*).—For culture in pots *Xiphion persicum* and *X. reticulatum* are the two best and cheapest you can employ. Several bulbs should be potted together in a 48 or 32-size pot, in a rich light compost of loam, leaf soil, and sand, with a small proportion of well-decomposed manure. Place the pots near the glass in a cool house or frame, and the plants will flower several weeks before those out of doors. The Spanish Irises should be planted during the present month or early in the spring.

Bracken for Mulching (*Sussex*).—The bracken referred to as employed for covering the ground between the rows of Strawberries was placed on the beds when the plants commenced flowering, and consequently had been cut during the preceding autumn. The bracken is stacked for the winter and cut for use in the spring, the same as cutting hay. The Strawberry beds were heavily watered before the covering was applied to the surface.

Farfugium grande (*A. Boyle*).—The variegated form of this plant is usually the most marked when the plants are grown in rather poor soil, and in a position not too moist and shaded; but slight shade is not objectionable. We have recently seen plants in the most satisfactory condition growing in shallow soil, and shaded from the mid-day sun from 10 A.M. to 4 P.M. Try your plants in a similar position.

Wintering Mentha Pulegium gibraltarica and Herniaria glabra (*Derby*).—The former will pass the winter safely in a dry position on the

south side of a wall or fence, small tufts being planted at the present time, to become established before winter. It is well, however, to plant them so that they can be covered with handlights or a frame in very wet or severe weather. They may also be wintered in boxes in a cold frame, to be well ventilated during all favourable weather. *Herniaria glabra* is perfectly hardy.

Grapes Decaying (*J. M., Cheshire*).—Various causes have contributed to the very unsatisfactory state of your Grapes. In the first place, the Vines appear to have been rather too heavily cropped, and when such is the case the skins of the berries are always deficient in texture, and consequently the fruit does not keep well. Next, the bunches were not thinned sufficiently for keeping for three months and more after they were ripe. They were thinned correctly for use in June, but not for hanging until the present time. Further, the atmosphere of the house has been kept too moist and close, and mouldy berries have not been cut out so promptly as was desirable. Possibly the house is in a damp position, or there may have been some leakage from the roof. When Grapes are ripe and the slightest appearance of mould appears on any berry that berry should be cut out, or the mould speedily spreads through the entire bunch. With more vigorous root-action the fruit would be produced in better condition for keeping after the crops were ripe.

Stopping and Training Chrysanthemums (*Artisan*).—If you require a few large blooms on each plant for exhibition purposes the axillary growths which you show in the sketch must be pinched out; but if you desire a great number of smaller flowers to produce a gay effect in a conservatory and for cutting for vase decoration some of the uppermost growths may remain. The leading growths must not be stopped now. The shoots on the dwarf specimens must be trained so that when finished the plants have somewhat of the form of an inverted deep saucer, the flowers being at regular distances all over the plant, and of the requisite height for forming a smooth surface. Much judgment is necessary in training them so as to produce the result required, some shoots having to be bent considerably to bring their points to a given position, and the growths of your plants are not yet long enough for this to be done. As to continuing training the shoots horizontally, that must depend on the question of your having "stuff enough" to fill up the centre well.

Pruning Climbing Rose (*A Reader*).—If the other portions of the plants are strong and healthy you may shorten the rampant growths now, and if very crowded remove some of them entirely; but if the older portions of the plants are weakly and not likely to produce good flowers, then you must retain the firmest, short-jointed, and most promising of the young growths, cutting the older and weaker parts away. No one, however, can satisfactorily answer a question such as yours. We can only make suggestions, to which you must bring your own thought and intelligence to bear in carrying them out. You had better invite some friend who has a practical knowledge of Roses to see your plants, and he will probably be able to give you some useful advice. Young growths of Roses are not more liable to injury by frost than is the older wood of the plants, if as much

Cyperus alternifolius variegatus (*Idem*).—You have overpotted the plant, and employed too rich soil. Gradually withhold water, keeping the soil comparatively dry during the winter; and in spring when fresh growth is commencing divide the plant, potting the portion with variegated leaves in much poorer and very sandy soil.

Hardy Fuchsia in Scotland (*Amateur*).—It is impossible to name the plant from a spray simply sent in an envelope, and which arrived in a much crushed and withered state. Possibly, however, it is *Fuchsia Riccartoni*, which is very fine in many parts of Scotland. The best and quickest mode of securing flowering plants is by dividing the roots of some healthy young bushes. Failing these you must obtain cuttings. The surest mode of obtaining a stock of young plants is to insert cuttings of the growing shoots in spring in pots of sandy soil, to be plunged in a heated frame or propagating house, and watered and shaded to prevent the foliage flagging. These cuttings strike freely, and if duly potted and eventually planted out soon make floriferous bushes. Cuttings of matured young shoots inserted now in light soil in a cold frame will also strike, but not so readily. These cuttings should be 6 inches in length, and inserted 5 inches deep, only one bud and joint being above the surface of the soil, and they should be protected from frost during the winter.

Wintering Potatoes (*Subscriber*).—We prefer the Potatoes placed in thin heaps on the level of the ground rather than in excavations or pits below it, but by the former plan greater care is requisite in protecting the tubers from frost. The site should be dry and firm, from 3 to 4 feet wide, the tubers being neatly piled so as to form a sharp ridge or apex. They should be perfectly dry when placed in the heap, not one diseased tuber being admitted. A covering at least 6 inches in thickness of very dry and straight straw should next be given, then with the spade commence digging a foot from the straw all round, and continue that thickness of soil over the entire heap. For ventilation 3-inch drain pipes may be placed on end at intervals of 3 or 4 feet, their ends being just, and only just, above the soil at the apex of the ridge. These ventilators must be securely closed during wet and frosty weather. With thin heaps of perfectly dry sound tubers carefully covered as directed we do not find ventilators necessary in wintering Potatoes. When several tons of Potatoes are stored in very large heaps drain pipes are often conducted quite through the centres of the heaps and out of the tops, and if the tubers are damp when stored the practice is a good one. Such ventilators, however, must have attention, or they do as much harm as good.

Grapes for Succession (*Old Subscriber*).—We presume you require as many varieties as possible consistent with good quality. In the cooler of the two houses you may try the following:—Four Vines of Black Hamburg, two of Madresfield Court, and one each of Buckland Sweetwater, Foster's Seedling, Dr. Hogg, and Duke of Buccleuch. The last-named is a grand Grape, that many, however, fail to grow well, and in case it should fail with you we advise you to plant it near a Black Hamburg, from which you can train two rods if "the Duke" has to be removed. Take the same precaution, too, in planting Madresfield Court, the berries of which crack seriously in some places, otherwise it is a fine autumn Grape. In the other house plant four Vines of Muscat of Alexandria, two of Lady Downe's, and one each of Mrs. Pince's Muscat, Mrs. Pearson, West's St. Peter's, and Gros Colman. Grown in heat the variety last named is often very good, and when well finished has a noble appearance. We have thus named eleven black and nine white Grapes, all of which are good when well grown; but no varieties are so useful as the Black Hamburg and Muscat of Alexandria. The Vines for permanent growth should not be less than 3 feet 6 inches apart.

Growing Tomatoes in Winter (*R. D., Liverpool*).—If a start is made at the present time it should, if possible, be with strong established plants in 5 or 6-inch pots and showing their first bunches of bloom. Failing these cuttings may easily be struck in heat, or, as a last resource, seed may be sown at once. Sow thinly and place in heat, and when the seedlings are up keep them as near the glass as possible; prick them off when in rough leaf, the strongest

singly in 5-inch pots, and the weaker in opposite pairs in 6-inch pots, the former destined for the house heated with fires. When about 6 inches high and before becoming much rootbound place the plants singly in 12-inch pots, allowing room for a liberal top-dressing to be given when the first cluster of fruit is set, stand the pots close together and train accordingly. A strong bottom heat is unnecessary, but the nearer the pots are to the flues the quicker will the crops mature, and, what is of great importance, the greater will be the amount of water required at the roots. The pairs may be planted out in the side beds prepared exactly the same as if for Cucumbers, training the plants about 18 inches apart. Afterwards treat them in each house, as far as temperature and moisture at the roots are concerned, similarly to Cucumbers. Suitable soil consists of two parts turfy loam to one of partially decomposed manure, using it rather fine for the seedlings, and roughly broken up for strong established plants. Cuttings may be inserted round the sides of well-drained 6 or 8-inch pots, and afterwards treated similarly to the seedlings. The simplest and most profitable plan is to grow them with one stem only if sturdy, rubbing out all side shoots, and if weak stopping the laterals at the first joint. It is a great mistake to starve the young plants in order to make them fruitful, as they never fairly recover from the effects of it. A fresh batch of plants should be raised early in the new year to replace the old exhausted plants, and from these probably will be taken the most remunerative crops. Frequent top-dressings and plenty of liquid manure are very invigorating to the Tomatoes. Hathaway's Excelsior and Earley's Defiance are two of the most profitable varieties to grow, the latter being the heaviest cropper, but scarcely so attractive in appearance as the former. It may be found necessary to impregnate the blooms during the dull winter months. The width of the house, 70 feet long, intended for Tomato-growing may be about 10 feet, allowing a 3-feet-6-inches pathway through the centre, the rest to be taken up by the pits. A flow and return 4-inch pipe for bottom heat in each pit, and the same on each side of the house for top heat, will be sufficient. The house to be span-roofed, and if possible running from north to south, and might at any time be utilised for Melon and Cucumber-growing. Or if you prefer it the house may be 15 feet wide and span-roofed. This would allow space for a centre pit 6 feet wide to be heated with two flow and one return pipe, to hold four rows of plants 18 inches apart in the rows, to be supported by stakes. There could be a 2-foot pathway round the pit, and the rest of the space to be taken up by the side pits in which to have the plants for fruiting up the roof. Three pipes, two flows and one return, arranged one above the other round the outside of the centre pit, would be sufficient for top heat. One pipe if it could be so arranged would be sufficient bottom heat for the side pits. Such a house ought to grow a great weight of Tomatoes, and it would make a capital plant house at any time. In your district probably a taste for Tomatoes has yet to be created, and therefore it is advisable to proceed somewhat cautiously. At the present time the London markets are over-supplied with them, one salesman alone having had a ton weight to dispose of on one day. These are grown principally in houses devoted to the propagating, bedding, and other plants for the markets in the spring. From March up to June Tomatoes are in great demand in London. If a good market is found for Cucumbers, we advise that half the space at command be given up to them, at all events for the present.

Names of Fruit (T. S.).—1, Belgian Purple; 2, Washington; 3, Drap d'Or; 4, Emerald Drop. (W. D. Paine).—Red Autumn Calville. (Sarnia).—Cumberland Favourite. (Epps box).—Your Plum appears to be Lawson's Golden Gage. (F. W. Warren).—The Strawberry is the Royal Hautbois. (Hurst & Son).—1, Hawthornden; 2 and 6, Claygate Pearmain; 5, Dumelow's Seedling. The others we cannot determine in their present green state. (W. H. D., South Wales).—The Pear is Comte de Lamy.

Names of Plants (F. W.).—Clematis tubulosa.

POULTRY, PIGEON, AND BEE CHRONICLE.

SHED ACCOMMODATION FOR CATTLE.

HAVING on previous occasions referred to the best methods of feeding cattle we now propose to avoid that part of the subject in a great measure, in order to give more direct attention to the accommodation whereby the animals may best be cared for under cover, or partially so. There are several modes advocated by men of experience in different parts of the kingdom, and these may be enumerated as box feeding, stall feeding, shed and yard feeding, and covered yard accommodation. It is not easy on many estates for the tenant to obtain such buildings as are really necessary for carrying on the business of the winter feeding of cattle successfully. In various instances the proprietor cannot afford the cost of new erections in connection with farmsteadings. In some cases even strong prejudices interfere and prevent such improvements as are desirable; and it is unfortunately the fact, whatever may be the cause, that although much has been done during the last twenty years towards improving farm buildings generally, yet if we observe the state and condition of them in almost any part of the country there is a serious and lamentable deficiency in the arrangements, which should enable the occupier to carry out his business with advantage whilst engaged in the production of

meat and manure. We will not further enlarge upon the subject, but enter upon the details of our own practice and that of others of experience whose doings may be safely relied on.

We will allude first to boxes as the means of accommodation for stock, and under somewhat varying circumstances. To erect new buildings is very expensive, the cost being more by from 25 to 30 per cent. than it was twenty or thirty years ago; it is well therefore to look over existing buildings carefully to ascertain whether any of them can be altered and improved. When we have found homesteads out of repair we have frequently altered them, and with new and improved internal arrangements have increased the value of the buildings at a cost but little exceeding the cost of necessary repairs. We have, for instance, arranged most convenient boxes for feeding cattle by internal fittings in an old barn, and there are probably few new buildings which offer superior advantages, especially when thatched, for such boxes are cool in summer and warm in winter. A certain amount of warmth or evenness of temperature is of the greatest importance to hairy animals like cattle, for they are unlike sheep, which are kept warm by their woolly covering; besides which it is now well understood that warmth is equivalent in the winter months to so much food, hence the economy obtained by box accommodation. On various occasions we have introduced moveable fittings in the barns, so that corn may be secured in them, which may be thrashed out early enough for the fittings to be replaced, and the boxes occupied by fattening cattle during the winter and spring months. The advantages of this plan are self-evident.

We will now state our plan of arrangements, which is to raise a feeding path 4 feet wide down the middle of the mows of the barn, leading out of the old barn floor, which is utilised for the store of food and its preparation. The boxes being made on each side of the feeding path must, of course, be in size according to the width of the building, 10 feet by 10 feet being a useful size, but we prefer 10 feet by 12 feet for full-grown cattle, besides affording space for pairs of young cattle when required, which may be fed in company, two together. These boxes are fenced entirely after being excavated 18 inches to 2 feet in depth by three larch fir poles of from 4 to 6 inches in diameter, but not sawn, as whole poles only will bear the pressure of the cattle. Three poles are sufficient as a division between each box, placed at about 2 feet apart, and whether these are fixtures or moveable they answer an excellent purpose at very slight cost, and will endure for many years; but the poles should be cut at the time of year when the bark will strip off, or a grub is bred under it which eats into the wood and destroys its durability. In excavating the boxes we have never found it necessary where the soil is firm and dry to use concrete or other materials at the bottom of the boxes. The only care required is to pin-up and secure the foundation of the barn walls. In our method of using the boxes, which we always fill-in at the bottom with about 12 inches of dried earth, peat, or ashes previous to straw being added for littering the cattle.

We will now allude to the erection of new buildings to give box accommodation, as it will be only in some instances that old buildings can be found equal to or well placed for our requirements. We will illustrate our recommendation by taking a double row of boxes with a feeding path between, which may be lengthened or multiplied to any extent that may be necessary, in accordance with the number of cattle to be kept or fattened on the farm; a convenient width of building being provided for a double row of boxes, 10 feet each, with a 5-feet feeding passage between, with a roof of 30 feet span; the boxes may be made 10 feet by 10 feet, or 10 feet by 12 feet, as may be required. The passage down the centre gives room for conveying food and litter to the boxes. The walls supporting the building may be of brick-work with sliding doors, one to every three boxes on either side,

opening so that manure, &c., may be removed conveniently, or earth, &c., filled-in as required. The food store and space for the preparation of cattle food is a separate matter, and will have to be considered in its relation to other buildings on the farm, except only that it should be contiguous to the cattle box range. In the event of these double rows being increased to two or more the passage between the boxes should be widened to 6 feet with a tramway, so that food, litter, &c., may be conveyed by truck to the boxes, and the manure removed in the same way at certain periods. In case of additional rows being added the roof may be upon the ridge-and-furrow principle, supported by iron pillars for all except the outside walls. All roofing may be composed of galvanised corrugated iron, with small elevated ventilators on the top at certain distances. The division of boxes may be of wooden rails, or they may be of hollow round bar iron made in lifting panels (moveable, but keyed-in for use), water being laid on and feeding troughs to rise or fall with the manure in the boxes. Anything beyond our statement is a builder's question.

We now proceed to consider the method of littering the boxes, for after having earth placed 10 or 12 inches deep in the bottom, litter of straw or other materials will be used as cleanliness dictates. About 18 or 20 lbs. of straw will be required daily to each box when no excrement is removed. There is, however, some difference of opinion as to the length of the straw used. Some advocate chaff about 4 or 6 inches in length, or even shorter, as they say it becomes more absorbent; but we dislike the expense of cutting by machinery, and we advise the straw to be used in longer pieces, say from 12 to 15 inches in length. For this purpose we tie the straw into single bond trusses, and use a thatcher's knife to divide it at the bond; this makes the straw fit for use, and it will then bind down firm with an even surface. As a case in point, some thirty years ago, when box-feeding was in its infancy, we were asked by a home farmer belonging to a nobleman's establishment to call and see his box system, which he said he could not think would answer, and wished for our opinion and advice, as his cattle made little or no progress. On inspecting the buildings we found them everything which could be desired, but the boxes were littered with straw chaff, cut nearly short enough to feed the cattle upon, and without any earth for absorbing the urine. Some very fine North Devon oxen were in the boxes, and well fed—indeed, overfed as regards the quantity of cake allowed. It was stated that the oxen had been in the boxes ever since the previous October, the time we visited them being February. We noticed that the bedding reached above the animals' knees, and asked the herdman to take a prong and lift a little of the litter; on doing this a volume of steam ascended immediately. We then explained to the home farmer that it was no wonder the cattle did not thrive living upon such a reeking mass of manure, and that it was lucky the animals had not died; that their ill condition was caused by the bedding being cut so short that it would not bear the weight of the cattle, and at every movement, instead of treading the manure into a firm compact mass, the animals were kneading the litter into a state of fermentation, injurious alike to the health of the cattle and value of the manure, thus showing how easily the best systems of management may be perverted by the omission of one item of practical detail. The utilisation of boxes upon pasture farms, or where straw is scarce, may still be obtained, somewhat upon the plan in use by Mr. Meech years ago—that is, a sparred floor; but we think it should be made to rise or fall with the accumulation of manure, to prevent a strong current of air under. The best plan is to place dried and screened earth at the bottom of the box, in order to absorb the liquid and solid excrement as it falls through the sparred floor, and by the daily addition of dry earth or ashes, gypsum, &c., swept through the grating the accumulation in the pit will be found to fix the ammonia in the manure, and make the floor healthy for the cattle above it.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—In various districts the harvest is not concluded, therefore the horses will still be employed in carting the corn and pulse. In many cases Beans are still in the field, but the sooner they can be stacked the better, in order that where Wheat is to follow the Bean crop the tillage may be proceeded with without delay. In cultivating Bean stubbles the land should not be ploughed in the ordinary way with a whole furrow, especially where couch grass prevails, but may with more advantage be first rafter-ploughed and then scarified across with the points, not the shares, for in this way the grass, &c., will be combed out and left on the surface to be dealt with by harrows, roller, &c.; but should the land have been clean-ploughed the grass will be turned under and buried, so that it will require more than double labour to work it out; in fact, by such a mode of proceeding it is never properly cleaned the same season. This remark

applies to all autumn cultivation, except the land is quite free from couch grass. We notice that all over the country steam power is in full operation, and this is in every case advisable, for it not only eases the horse labour but completes work for which there is only a limited time at command; for when once the autumn rains commence it seldom happens that cleaning the land can be continued. In the early districts and on the chalk hill farms the drawing-out of manure will be going on, and the spreading and ploughing may follow as soon as possible; for upon these soils, particularly in bleak situations, the Wheat requires to be sown the last week in this or the first week in next month. Upon the heavy land farms also the same work applies, but the seed time may be delayed until the end of October with advantage. With reference to the drilling of Wheat upon heavy land we again advise the home farmer to drill the lines 12 inches apart, otherwise it is in some seasons quite impossible to insure a successful growth of the plant; for after a wet winter, when the land is close and hard on the surface, the plant often looks pale and sickly, in which case if it is not horse-hoed by moving the surface the crop will be deficient, as sickly plants only produce small ears at harvest. We advise the sowing of pedigree corn, and if this costs rather more money less seed is required, especially if it is drilled at the earliest season and at the wide distance. Although from some cause or other the plant may be thin in the spring, yet pedigree grain will make up more deficiencies than the ordinary sorts, because it will always produce a larger ear. Trifolium sowing should now be completed, for although the late sorts may be sown as well as the early variety, yet the seed time must not be deferred. Winter Vetches and winter Oats may now be sown in admixture—1½ bushel Vetches and half a bushel of Oats. Rye, also, should now be sown if required for early spring food, and the winter seldom kills, only checks, the growth however forward it may be. Winter Beans may now be drilled, and we do not like to trust to them entirely, but recommend the mixture of half a bushel per acre of winter Vetches. This will not interfere with horse or hand hoeing in the spring, but as soon as it is completed the Vetches reach across the lines and dominate the weeds, which otherwise injure the growth of the Beans, besides which both Beans and Vetches seldom suffer from blight in the same season. The feeding off early Turnips has been going on lately with great benefit to the sheep and the land also, and as there is a full crop this year a portion may be carted off for feeding cattle with great advantage. Old Saintfoin leas which are due for ploughing and seeding with another crop, may in a season like the present be pared and burned or autumn-cleaned, and sown either with Wheat or left for seeding with Oats in the spring, after being deeply ploughed. Nearly all the late sorts of Potatoes will now be forward enough to plough out; and we are pleased to say that the disease has not spread lately, nor do we find that those which have grown out are injured as was expected; in fact, the fine weather has so far altered the Potato crop that a full produce is likely to be well secured. We find in some cases that the gross haulm of the Champion variety has been cut off and used for feeding dairy cows this autumn with some advantage. Dairy cows which are used for suckling calves for veal will now have an advantage in some respects compared with those for making butter, cheese, or selling milk, especially when we consider how deficient in many instances is the milking process carried out for want of care and attention by the hand-milkers, and we have yet no milking machine which in our opinion answers the purpose in all respects. Again, in referring to the custom of allowing the cows to go dry for several months before calving, this, together with imperfect milking, is a serious evil, and a large number of animals lose their teats or suffer at calving time with the downfall in the udder. Great injury arises from the cows in such cases making internal fat in various ways, and it is not sufficient, if it could be proved, that cows allowed to go dry for a considerable period give more milk after calving. We have a set-off against this by a large number coming to grief, which is not the case when calves are suckled for veal throughout a lengthened milking period.

BUYING EXHIBITION CHICKENS.

We live in an age of competition, and few of us are now content with our cows, or pigs, or dogs, or poultry unless they have some chance of competing with success against those of our neighbours. The season of poultry shows is coming round, when all breeders seem to take an interest in their well-bred stock. Unfortunately in many this interest is spasmodic and periodical, and only recurs at this time of year; the result is that either their exhibits make a very sorry figure, or that they buy from more painstaking breeders. It is a well-known fact that year after year certain famous and successful exhibitors buy all their exhibition chickens; they are not able or do not care for months to bestow on the little growing birds the attention which alone will secure success afterwards in the show pen.

It always seems to us that there must be something a little unsatisfactory in this systematic purchasing, but those who buy know their own business best, and the liberal prices often given for first-rate young stock are a great encouragement to clever and perhaps poor breeders. Apart, however, from such regular buying for exhibition, many a would-be exhibitor begins by pur-

chasing some prize chickens, or such as are likely to become such. The plan is certainly a good one, for it is a sore tax to patience to begin in the autumn with a breeding pen which perhaps may never produce good chickens, and if it does, whose owner may not be able to choose the best. Many of the greatest and most successful exhibitors have thus begun. We remember how "the Henwife" relates in her personal experience that the beginning of her famous career as an exhibitor was the purchase of a pen of Dorkings in England, which subsequently won honours for her at all the Scotch shows. We know many a fancier who has first been taken with the poultry mania on seeing an exhibition in the early autumn when cockerels and pullets are in the pink of condition and the fullest bloom of plumage. The great shows are still to come, and birds purchased now even at high prices may easily win more than their cost in cups and prizes at the winter shows, and may lay the foundations of a lasting fame in the poultry line for their proud purchasers. To love a good bargain is said to be inherent in human nature; nevertheless, unless we are much mistaken, there is considerable charm in regarding a costly purchase when it turns out well and answers the purpose for which a liberal outlay has been made.

There is much pleasure in the first laurels won in any contest, and certainly we have never known more enthusiastic or painstaking fanciers than some of those who have begun by a spirited speculation in prize birds. As we have said, interest at once centres on such; they can almost immediately be shown in their new owner's name, and by comparing them with their competitors a novice may soon learn more than he can from pages of descriptions or daily admiring surveys of his home stock. Many of our home-bred Swans turn out in the show pen to be very ordinary Geese; yet so convinced are some fanciers of the superiority of their own feathers that nothing but ocular proof will make them see their deficiencies. Another argument in favour of the purchase of early exhibition chickens is this: Really good birds can in September generally be purchased at moderate prices. The yards of most breeders are crowded, the cockerels begin to quarrel, and often if not parted with some of the best stock has to be sacrificed. Those, too, which are now winners may not win hereafter, and the thought of this naturally weighs with sellers.

This brings us to the point of our subject—viz., to some hints on the selection of young show stock. To begin with, precocious birds should be avoided; we mean such cockerels and pullets as are often seen, still not nearly full grown, yet with all their full adult plumage and highly developed combs. Such birds have been forced on, and will grow little more; an inexperienced judge is often taken with their prettiness and condition, and even the best judges sometimes cannot help putting them in prominent positions when all other competitors are still combless chickens. Again, purchasers should look out for any signs of severe moults. Early chickens which have quickly developed the plumage of cocks and hens, especially pullets which have laid, often go into deep moult, which unfits them for exhibition through the greater part of the autumn. A practised eye will easily detect such drawbacks, but a beginner may not find it easy to do so, and, indeed, no one can be certain that any young birds will remain continuously in good plumage. Moults come on suddenly and capriciously, and depend much upon temperature; the overheating of a show room will sometimes throw chickens into the moult.

We advise all beginners to get introduced to some well-known fancier of the breed he is inclined to take up, and to follow his advice in the selection of birds to start with. There seems a general bond of sympathy between true fanciers. We must say that we have known many who, though total strangers at first, have done all in their power to assist a promising novice in poultry or Pigeon matters. If it is impossible to get advice on the purchase of birds at a show, which is generally preferable, we advise a young fancier to write directly to some exhibitor of repute, state his requirements and about the price he can give, and trust to receiving his money's worth in the shape of good birds. When this course is straightforwardly pursued we believe that instances of cheating are very rare. Too often a beginner reads up a list of points in some poultry book, looks out for the advertisements of first-prize cup birds, answers one put in by some unknown individual, who has probably never won a prize at all, or if he has, only at some fifth-rate village show, describes the perfect and ideal bird, and in return receives a reply that he can have such a one for 15s. or £1. Of course some worthless creature arrives, the buyer is disgusted, complains that fanciers are rogues, and often buys no more. If more confidence were placed in really well-known and great breeders, and if the ignorant really confessed their ignorance, and instead of pretending to expect perfection would ask the description of birds at a

certain price, their merits and their imperfections, we believe that much disappointment would be obviated, and that many a useful young bird both for breeding and exhibition might at this time of year be picked up at far less than the exorbitant prices which winning specimens always command by the time of the great autumn shows.—C.

VARIETIES.

GOAT SHOW.—An Exhibition of Goats will open this day (Thursday) at the Alexandra Palace, and remain open for a week. About a hundred specimens have been entered, the exhibitors including the Baroness Burdett Coutts, Lady Pigot, and many members of the British Goat Society, whose Honorary Secretary, Mr. H. S. Holmes Pegler, will act as Judge.

— FIELD POTATOES IN SCOTLAND.—A correspondent communicates the following on this important crop:—"Regents and Victorias will be very excellent. The disease has been stopped by the extremely dry weather, but I have seen mildew very bad indeed. With regard to the Champion there will be some disappointment this season. Not only will the smallness of the crop have to be reckoned on, but owing to the abundant crops of the above-named superior Potatoes, the stocks of Champions will have to be sold at a low price. I have been for a few weeks past doing a kind of voluntary penance testing the quality of new Potatoes, and what a pleasure it is to get back again to old-fashioned sorts!"

— THE HARVEST AND CORN VALUES.—That the harvest is a good one may be estimated by the price of British Wheat last week, which was 42s. 2d. per quarter. This was several shillings per quarter lower than it has been on an average of several years past. The average price of Oats last week was 21s. 8d., which was much below the average price during the corresponding weeks of several preceding years. The same may be said of Barley.

— AGRICULTURAL EDUCATION IN ITALY.—Arrangements are being made by the Italian Ministers of Commerce and Agriculture for the institution of "Ambulatory Agrarian Schools," after the pattern of those which have effected such good results in parts of Germany. A number of professors of the sciences practically allied with agriculture will lecture and hold classes in the principal towns of these provinces during a few months of each year, in order to instruct the country folk in the most rational methods of cultivating their soil. The Ministry has also determined to erect at once a number of specialist agricultural schools at Avelino, for general agriculture; a second in Florence for pomology and horticulture; and a third in Bari for Olive culture. Similar schools are planned at a later date for Alba, Modena, Catania, Brindisi, Alghiero, and Ferrara.

— FROM HARVEST TO HARVEST.—In the twelve months ending August 31st, 1880, the import of Wheat into the United Kingdom reached 59,815,691 cwt., equal to 13,803,621 qrs.; and when we add to this the import of Wheat flour—which amounted to 10,431,726 cwt., or 2,980,493 qrs.—we find that we received from abroad no fewer than 70,247,417 cwt., or 16,784,114 qrs., of Wheat and Wheat flour. In the twelvemonth ending August 31st, 1878, the amount was 62,255,125 cwt., or 14,808,966 qrs.; and in the twelvemonth ending August 31st, 1879, it was 60,849,823 cwt., or 14,543,607 qrs. Our other imports of corn in the twelvemonth ending August 31st, 1880, comprised 31,870,896 cwt., or 7,436,542 qrs., of Indian Corn or Maize; 12,382,665 cwt., or 3,467,147 qrs., of Barley; the very large quantity of 15,622,912 cwt., or 5,681,059 qrs., of Oats; 2,002,772 cwt., or 445,061 qrs., of Peas; and 2,754,518 cwt., or 642,721 qrs., of Beans. The grand totals are as follows:—In 1877-78 the twelvemonth's import thus classed under the title of "corn" amounted to 131,430,348 cwt., or 33,858,689 qrs.; in 1878-79 it was 124,866,538 cwt., or 31,510,900 qrs.; and in 1879-80 it reached 134,881,180 cwt., or 34,455,644 qrs. In the last of these three periods, compared with the first of the three, the increase in Wheat and Oats was nearly counterbalanced by a large decrease in Indian Corn and in Barley, so that the grand totals show no very great difference.—(*Times*.)

— THE EGG TRADE IN AMERICA.—This is referred to as follows by Messrs. Read & Pell in their report on American farming:—Eggs

come to market wholesale in New York in barrels containing seventy dozen, priced at 15 cents per dozen. They have been preserved for several months in refrigerators, and are delivered from Toledo [in Ohio. One dealer cleared £3000 by a rise in prices in 1878. He bought at 6 cents a dozen, and sold at from 22 to 25 cents. Between June and October they are packed in Oats, which in New York are worth the cost price to the packer in the west. The farmer is said to make more by eggs than by any other produce. They come over 1500 miles from Omaha on the Missouri. The supply after the abolition of slavery became more abundant, as the free blacks in the south are poultry keepers. In 1874 eggs were sold in New York in January at 40 cents the dozen, before the month was out they fell to 12 to 15 cents. The home consumption in New York has materially increased.

— TOP-DRESSING EXPERIMENTS UPON GRASS LAND.—The following experiments have been conducted upon the Rotherfield estate in Hampshire, and as they show conclusively the value of cheap natural fertilisers, the result cannot fail to be interesting and useful at a period when money is by no means plentiful. The soil was a porous self-drained clay, contained little or no lime, and the dressings were sown on March 17th, and the plots cut and weighed on August 16th, 1879. Plots one-tenth of an acre. No. 1, 150 bushels of cut straw per acre; 2, nothing, do.; 3, 5 cwt. of salt, do.; 4, 5 cwt. of gypsum, do.; 5, 5 cwt. of kainit, do. The costs per acre of the above dressings were as follows:—No. 1 (about) 10s.; No. 3, 6s. 8d.; No. 4, 6s. 3d.; No. 5, 8s. to 10s. The amount of grass attributable to the various dressings was as follows:—No. 1, straw, 255 lbs. in excess of plot unmanured; No. 3, salt, 265 lbs. do.; No. 4, gypsum, 643 lbs., do.; No. 5, kainit, 548 lbs., do. Taking No. 4, then, we find for an outlay of 6s. 3d. we obtain 6430 lbs., or nearly 3 tons of grass—a most extraordinary result. Referring to some top-dressing experiments conducted on the same estate in 1875, the results of which were duly published in the *Agricultural Gazette*, we find that Peruvian guano, at a cost of £3 per acre, gave a return in grass of 7 cwt. per plot, or 3½ tons per acre. Compare this result with the quantity derived from an outlay of 6s. 3d., and the value of the experiment is at once apparent. The dressing, also, being especially adapted to the requirements of the finer grasses and Clovers, gives an indirect value by no means to be overlooked. The above plots were weighed again on August 2nd, 1880, with the following results:—No. 1, straw, 78 lbs. in excess of plot unmanured; No. 3, salt, 49 lbs. less than plot, do.; No. 4, gypsum, 111 lbs. in excess, do.; No. 5, kainit, 157 lbs. in excess, do. The result shows the effect of the dressings seventeen months after application.—C. E. CURTIS (in the *Agricultural Gazette*).

— HEALTHY AND PROFITABLE FOWLS.—Dr. A. S. Heath, in a paper read before the Farmers' Club, New York city, said:—"The reason why eight or ten fowls about the house of the mechanic, the gardener, or the labourer are more profitable is because of better feeding and less crowding, better sanitary conditions of yard and roost. Extent of grassy range for fowls is more important than provided food, for here they obtain not only air food but also insect food, which is the essential nitrogenous element necessary for egg-production. Equally important to extensive grass range are clean and airy roosting houses or sheds. The houses should have doors on the ground, to be left open in the summer, and at least two side slat ventilators should be provided. Running water is a most desirable and easy means of water supply. With this water supply without care or labour the food supply may be equally convenient and labour-saving. Drive four stakes into the ground so as to leave them 2 feet above the surface and 6 inches apart, and upon these nail two boards so as to make a table large enough to permit the fowls a footing around a nail keg in the centre, covered by a wide board and weighted by a large flat stone. This keg may be filled with corn or cracked corn, and having three or four augur holes near the bottom it is self-feeding. What runs out is lodged upon the table. It is kept clean and dry, and secure from rats and other vermin. This is a cheap, simple, and labour-saving manner of keeping fowls, and it will be found a most profitable plan. This grass range may be a small pasture or a large cow-yard. Fowls should never be allowed in stables or carriage houses. Their houses should be fumigated by burning half a pound of sulphur every spring and fall, while the fowls are

shut out for the day, and be well aired before roosting time. Not more than twenty or thirty fowls should be allowed to roost in one house, but two or more of these houses may be erected in the pasture or range, provided it is large enough. In this case the feeding place may be the same, only a barrel may be used instead of a keg to save trouble. The largest liberty and the most generous feeding, with an observance of cleanliness, will secure the best yield of eggs and the largest number of healthy fowls. This is the way to secure the largest profits of the poultry-yard."

HONEY HARVEST OF 1880.

THE accounts which are coming in from various parts of the country giving reports of the honey harvest are various. In some counties hardly any honey seems to have been taken. The mid-land counties seem to have suffered worst in every way, owing to the deluges of rain following upon the constantly recurring thunderstorms of June and July. Of course this weather must have been as disastrous to bees as to the farmer in respect of his corn and hay crops.

Here in the south-west of England I am thankful to say we have a very different tale to tell. Our dairy farmers are once more in good heart, and there is every prospect of a very good crop of every kind of produce save only of Apples. Our honey harvest this year in Somerset, Wilts, and Devon, so far as it has come under our observation, has been exceptionally good. My own apiary has done extremely well considering the difficulties our bees have to contend with in a very open and exposed country with no great floral pabulum to depend upon. On the whole there has been a fairly continuous supply of honey, dating from the middle of May. We have not to chronicle a period of starvation followed by an unusual glut of honey, as was the case in 1878, and in a less degree in the majority of fairly good years before that date. Indeed I must go back to 1861 for anything like the honey harvest we have had this year. The honey, too, throughout has been remarkably rich and glutinous. I have seen none of that watery honey which we usually have in large quantity towards the end of July and at the beginning of August, which alone can be fairly called "crude" honey. It is indeed so thick that the combs will not sling well, in consequence of which we have had to return combs to the hives containing a good deal of splendid honey.

To the absence of glut in the inflow of honey I attribute the fact that so little perfectly pure honeycomb has been harvested here. There has been much breeding going on and too much pollen stored even in supers twice storified; but the run honey, which has been so much the greater in quantity, is worth twice as much as in ordinary years. Being still in the midst of the harvesting process, I cannot exactly tell the nett total of serviceable honey and honeycomb, but I do not think it will be much short of 250 lbs. The demand for it being great I am able to sell a good deal, and consider that the value of it to me fully reaches £13, our selling price being 1s. 2d. per lb. for honeycomb, and 1s. per lb. for run honey. This I consider the nett profit of the year, as the swarms I sold in June will more than pay for the outlay incurred last autumn and during the following spring in feeding the eleven colonies which survived the winter. Exclusive of about 10 lbs. of honey furnished by swarms of the year the harvest of honey given above has been supplied by eight stocks, no hive yielding over 50 lbs.; of course there has been no brimstoning, and the apiary throughout is in good health and strength with plenty of food in most of them. In about a fortnight I shall commence gentle and continuous feeding for a month, so as to induce breeding during the last harvest of the year which comes with the Ivy blossom.

The result of the year's bee-keeping above given surely teaches the lesson *Nil desperandum*, and should encourage all to take the utmost pains and to spare no expense in feeding up their stocks of bees in good time during the warm days and nights of mid-autumn. Instead of all dying during the winter, as they certainly would have done, and left me in beggary as an apiarian, my stocks of bees now number twelve all in good health and full of promise, worth at least 30s. apiece, in all £18, and the profit of the year 13 lbs. additional, so that I am fully £31 better off than I should have been if I had despaired or neglected my bees as did so many of my hapless neighbours.—B. & W.

DIAGRAMS OF BEES AT SOUTH KENSINGTON.

IN your impression of the 12th ult., page 154, allusion is made to an award of a bronze medal to Abbott Brothers for exhibiting a set of diagrams, said to be "now perfectly well known, and in

which Abbott Brothers deal," and in the same paragraph the Judges are certainly not complimented on their taste in making the award. In reference thereto, may I be allowed to state that the firm I represent do not deal in the said diagrams, that they never have had or seen other than the one set alluded to, and that they have never offered them for sale? They were presented to me in 1877 by M. Rothschild of Paris, and so far from their being "perfectly well known," I have never heard of or seen anything like them except in the diagrams for which Mr. Cheshire was awarded a silver medal at South Kensington in 1879, and which have been since republished by the British Bee-keepers' Association.—C. N. ABBOTT, *Fairlawn, Southall.*

HOW TO ITALIANISE BLACK BEES.

THE following plan of the Rev. J. W. M'Niel, which we cite from the "American Bee Journal," may perhaps answer the above question, which has been submitted to us by Mrs. Elvey:—"Whenever anyone desires to italianise an apiary it is necessary to start right. The important matter first is to be certain to procure a pure Italian queen. When obtained and introduced into a hive, of which I will hereafter give my plan, then the work of raising queens from her may soon be commenced. The frame hive of some make is necessary in this work. Of whatever kind used, be certain to have all the frames of the same size; this will obviate a great deal of trouble and loss of time, not only in the work of raising queens, but also in the general management of bees. After all the eggs of the black queen in the hive into which the Italian queen has been introduced have hatched and been capped in their cells, then the work of raising queens may be commenced, provided the Italian queen has been laying. This being sure, my plan is to remove a hive from its stand, placing an empty one in its stead, and in this place a frame of comb with eggs in it from the Italian queen, then return to the hive, having been removed from its old stand, and blow a strong draught of smoke into it; many of the bees will return to their old stand, and those, together with others out foraging, will enter this, making a nucleus—if not strong, still continue to agitate the bees or the removed hive until the nucleus is a good-sized colony.

"This nucleus will in a few days commence queen cells, making from three to fifteen. These must be closely watched, and from the day the first is capped allow only six or seven days to pass before all the queen cells except one are carefully cut out, and place one in each of the queenless nuclei. These nuclei may have been previously prepared by destroying a queen and dividing up the hive. Be certain that the nuclei have neither queens nor queen cells. In these introduce the queen cells into the combs into about the same position as those made by the bees. These queen cells will soon hatch, and after the queens are fertilised they can be introduced into hives of the common bee.

"It may be well to remark that the safest plan I have tried is to cage the young queens, destroy the black queens into whose hives it is desired to introduce the young queens. Suspend the cages about the centre of the hive, having placed a small piece of comb in the bottom with honey in the cells, upon which the queens can feed themselves. After the cages remain there about forty-eight hours take them out and cork them with a small piece of thin honeycomb, and suspend them again in the hives. The bees of the hive will encage the queens by removing the comb from the mouth of the cages. After suspending the cages thus the second time, do not disturb the hives in less than three or four days; after which the hives may be opened, and, if the queens are alive, they can soon be found among the black bees, for the reason the Italian queens are of a bright golden colour. By the above plan anyone may in a short time displace all their black queens and place in their stead the Italian."

OUR LETTER BOX.

Duck Management (R. T.).—The food of Ducks and ducklings, and their digestive powers, seem to be of that happy character, so easy to find and so effectual when found, that we seldom expect to have much to say about them. We do not believe much in their weakness, unless they are improperly lodged or fed. No lodging is fit for them that has a brick, stone, or wooden floor. Either will produce eramp, and that will cause the staggering you speak of. Dry food is not good for them, nor is scrupulously clean food desirable. If they are kept tolerably clean, then add to their food a sod of grass put in the water. Give them Oats, oatmeal, Lettuces, and if you want them to grow and fatten quickly any scraps of raw meat you may have.

Chickens Drooping (Devon).—You chickens are suffering from chill, or from roup, or from some weakness. When they are first attacked they should be freely fed with bread steeped in strong ale; afterwards, both for cure and prevention, put citrate of iron or camphor in their water. The use of these two remedies will be found to save trouble, anxiety, and loss. Your fowls must have a grass run, and should be fed principally on soft food. Change of air, food, water, and above all of roosting, will often affect poultry.

Diarrhoea in Pigeons (T. S.).—Give them three or four pieces of whiten- ing or chalk daily, each about the size of a pea, and feed them on old beans until the diarrhoea ceases.

Food for Pigeons (N. O.).—Tares, if old, are perhaps the best food for Pigeons. As to linseed, it has been found in Germany that after the linseed harvest Pigeons are frequently ill, and die of diarrhoea; so that we would advise you to give it with a sparing hand, and add a few handfuls of common dry rice to your compound of tares, linseed, Peas, and Barley.

Bee Flowers (H.).—White Clover, Saintfoin, Trifolium incarnatum, Buck- wheat, Heath, Lime, fruit trees of all kinds, Raspberry, Gooseberry, and Currant; Laurustinus, Borage, Mignonette, and Nepeta Mussinii.

Driving and Uniting Bees (Busy).—Your super, which is two-thirds filled with combs and honey, should be taken from the hive at once, as the honey season is over. After the super has been loosened from the hive drive the bees down into the hive by smoke applied at the top. If some few bees remain amongst the combs of the super, take it into an attic or cellar of the house with an open window, in order to let the bees fly out and home. If the supers were left in the garden, the bees flying about would soon find it and take all the honey. The books you have been reading contain instructions for driving. If your hives are not of equal width so that they cannot fit and rest on one another, roll a tablecloth firmly round the rim of the smaller hive and thus overcome your difficulty. First drive the bees which are to be surrendered into an empty hive, then feed the bees of the hive to receive them, and in about an hour afterwards place the empty hive (with the driven bees) on its crown and lift the full hive on to it. All the bees will run up without driving, but will run faster if driven. This process of driving and uniting is a very simple affair. All beginners like yourself lack courage and self-confidence. After you have done it once your success will qualify you for more difficult work in the apiary. After the bees have run up lift the hive on to its board. You are quite right in thinking that the seasons have of late been unfavourable for honey-gathering.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

- 5th.—Morning fine with sunshine; afternoon cloudy; warm day and windy.
6th.—Fine with sunshine for short time before noon; dull, very cloudy after- noon with rain, which gradually increased from 6 P.M.
7th.—Dull morning; afternoon very fine and bright; starlight evening.
8th.—Fair pleasant day, but good deal of cloud.
9th.—Cool fair day, no sunshine.
10th.—Foggy in early morning; fine bright hot day; strong breeze.
11th.—Dull close morning; rain at 2.30 P.M., but not heavy until 4 P.M., from which time it fell at the rate of more than a tenth of an inch per hour until 1.30 A.M. of the 12th.

The absolutely rainless period of twenty-eight consecutive days ended on the afternoon of the 6th, but the amount was unimportant until Saturday 11th, when the heaviest fall of the present year occurred.—G. J. SYMONS.

COVENT GARDEN MARKET.—SEPTEMBER 15.

WE are still fairly supplied with Apples and Plums, both being sufficient for the demand, and prices firmer. Good Peaches are in demand, while Grapes remain the same as last week. Kent Cobs and Filberts are short.

JUDGES AND JUDGING AT HORTICULTURAL SHOWS.

As our neighbours the French observe, "It goes without saying," that the success of exhibitions depends in a great degree on the judging. However good an exhibition may be, and however able and assiduous the officials of the show, if any serious mistakes are made in the awards from time to time exhibitors become alienated and gradually drop off, and without exhibitors it again "goes without saying" there can be no show. The committees of horticultural societies are generally aware of the importance of securing good judges; but as not a few of those committees are composed of gentlemen who have necessarily but little practical acquaintance with the art that they so laudably endeavour to promote, they do not always succeed in securing the best men obtainable for adjudicating in the several departments of an exhibition. Occasionally judges are appointed, not because they possess special qualifications for the office, but because they are fortunate in being employed by some grandee who is also a supporter of the society. Such gardeners may be excellent judges, but, on the contrary, they may not possess the necessary qualifications, and there is always more or less risk of disappointment ensuing in some form or other when local men are appointed to adjudicate at provincial shows. All good gardeners are not good judges. Some do not possess the faculty of a quick and accurate comparison of the merits and failings of the several exhibits before them; others of a cautious frame of mind lack the virtue of decision and become nervous, then sometimes decide wrongly; others, again, have a great amount of self-assurance, and jump at conclusions—"knock off a show," as they say, "in no time," as if this were a proof of their competency. But even such men are not infallible.

Then, again, when good judges are secured they are not always judiciously apportioned. There are some, but not many, judges who are equally conversant with the merits of specimen plants, Orchids, florists' flowers, fruit, and vegetables. Such men may safely be sent into any department of a show. Others are specially competent, and these are the majority, in one particular branch. A gardener may be a first-rate judge of fruit, but quite "at sea" amongst specimen plants and florists' flowers. Another may be a thoroughly good plant judge, and quite out of his element amongst fruit. This is an important matter, and should always be remembered when the judges are being apportioned to the different sections of a show. I have seen three judges "doing" the specimen plants,

and two of them admitting they knew nothing about them, and have also seen fruit misjudged by first-rate plantmen.

Some men in the horticultural world appear to be very fond of judging, or of the guinea or two at the end of it. They, indeed, offer their services and seek appointments. Such judges do not hesitate to act in any department, and they may give satisfaction; still it is to be remembered that experienced and competent judges have no need to "seek for work," as they have more applications for their services than they can entertain.

It is the rule of some societies to have fresh judges at every show, while other societies employ the same men for, it may be, twenty consecutive years. As to this, it may be said that every plan that works well is good; but it cannot be denied that a great number of exhibitors are often heard expressing an opinion when they meet the same judges at the same show for half a lifetime, that "a change would do no harm." Changing the men every year may work well for a time, but the course is not the safest; for it follows that a very good man may be succeeded by one less competent, and superior judges are not so plentiful as to enable this system to be carried out indefinitely. As in other matters, the safest course is probably the mean between two extremes, and old hands should occasionally stand aside to afford younger men an opportunity of exercising the functions of censors. Two old well-proved judges to one new one is always a safe course, and a young or fresh man is being brought up to the efficient discharge of an important duty.

In the distribution of judges different customs prevail. At one show a certain number of classes are allotted to one judge who has to perform his duties alone; in other cases the judges work in pairs; in others, again, in triplets. Judging is necessarily costly when a number of adjudicators have to travel from two hundred to three hundred miles to perform their duties, and it is possibly thought that by the single-judge system there is a saving of expense. It is a question if this is really so. There are very few judges indeed who like to act alone, and the majority of them are twice as long in adjudicating on a given number of classes as two men would be. A single judge having no one to share his responsibility naturally hesitates long over every class for fear of making a mistake, and, be it understood, this very hesitation not infrequently leads to a mistaken verdict. I have seen one of the very best fruit judges in England in a most uncomfortable position, and in a state of perspiration when acting alone; but with a coadjutor the work would have been easy to him. In this case, as he afterwards admitted, he made one mistake, and said the judging would have been done in half the time if he had had an assistant. No doubt the majority of judges will coincide in this opinion.

The other extreme of judging in triplets is founded on the principle that a majority must decide the points at issue, and with two judges only, and their views being different on any exhibit before them, there can be no majority and no decision. As a matter of fact, however, the verdicts are usually given with unanimity, and the concurrence of two good judges is quite sufficient for all practical purposes. Where cost is no object let three judges be appointed by all means in every section of a show, but generally there is a decided waste of power by this plan.

Judging in pairs is for all practical purposes sufficient, and

is in the end economical, but some provision is necessary in case of a diversity of opinion between the two censors. This is very easily provided, and it ought to be done in a systematic manner. Each pair of judges should have the name of a referee written on their schedule—one of the judges in another class, whose appointment as referee in certain classes is also written on his own schedule. In case of two judges failing to agree they know directly where to send for the casting vote; the referee leaves his coadjutor for a few moments, brings "a fresh pair of eyes" to bear on the points in dispute, and has seldom any difficulty in giving his decision, while his colleague experiences no inconvenience by being temporarily left to pursue his duties alone for five minutes. This plan works well, and is equal to three judges in a section, for in practice the referee is seldom in request, in nine cases out of ten the two judges agreeing in the verdict.

It is a great mistake to unduly limit the number of judges, or, in other words, to overwork them. When the awards have to be made in a hurried and bustling manner mistakes are certain to occur, however competent the adjudicators may be. One of the greatest of all mistakes bearing immediately on this subject is the delay (which betokens loose and bad management) which occurs in staging the exhibits. According to the rules the tents have to be cleared for the judges say at 10.30 A.M. They enter the tent then, find all in confusion, have to "hang about" for an hour or two, and commence their duties an hour before the public are admitted, and complete them perhaps two hours after. Of all the inconveniences, even annoyances, pertaining to judging none is so great as adjudicating in a crowd of visitors. The work cannot be properly done then. The judges can neither satisfy themselves, the committee, nor exhibitors. No one should be in the tent with the judges and their officials, except the representatives of the press. These latter are always admitted, except under the officious management at some obscure local shows that are not really worth reporting.

A word may be said on the manner of judging. As a rule the point system is by far the best, but it is not always necessary to bring it into requisition. The value of some competing collections is apparent at a glance, while others require the closest and most skilled examination. Good judges, it may be observed, never like to give, say, equal first prizes to two competitors. The most competent of adjudicators will spend an hour over two collections in an important class rather than give an "equal first;" while others less competent find it an easy way of solving a difficulty. Still, occasionally the best of judges have no other course open to them consistently with doing justice to both rivals for their verdict. It is in such cases as these when point judging is of value. Take, say, two collections of fruit so close in point of merit that by comparing dish with dish it is a mere matter of chance which "has it;" but have recourse to careful point judging, and the question is reduced to a sum in addition, for the judges have agreed after a close examination of every dish the number of points to which it is entitled; but before they commence they must determine the standard of excellence, by an ideal number of points, of every kind of fruit exhibited. This subject was alluded to by Mr. Witherspoon in the autumn of 1879, and at an autumn exhibition he gave as points allowed—for a Pine ten; Grapes eight; Peaches, Nectarines, Melons, and Figs six each; Apricots and Plums four each; Pears, Strawberries, and Cherries three each; and Apples two. This will do very well, for any given number is not essential, but Pears are worthy of more than three points, and Apples more than two; and the matter would be simplified by allowing Pears four, and Apples three points. This system should also be applied to vegetable collections, and if carefully carried out few errors could occur, while the judges could afford to watch with equanimity the grumblings of outsiders.

Point judging is still more important in the large cut flower classes, say of Roses and Chrysanthemums. It is simply impossible to arrive at a correct verdict in determining the merits, say of very close stands of forty-eight Roses and thirty-six Chrysanthemums, without estimating each bloom by points. I have seen judges after much haphazard comparison of row with row and bloom with bloom decide on their verdict, but

before formally giving it bring the point test into operation, and this has quite upset their preconceived verdict. If they had adopted it at first instead of last they would have saved much time, and understanding the merits of every bloom their decision could not on any good ground be called in question.

I am tempted to dwell on the idiosyncracies of judges, for these are well known and are the cause of some amusement amongst onlookers. There is the noisy judge, the grave judge, the fussy judge, and the sober judge. The noisy judge gives utterance to all his thoughts, and the changes of his mind are floating audibly all over the tent. He is generally an old hand at the work, and looks upon it as a matter-of-fact duty to be got through in the best manner, not thinking of himself at all. The grave judge, on the contrary, appears to be impressed with the solemnity of his position, and acts in the most conscientious manner as if a nation were hanging on his verdict. The fussy judge always attracts notice; he cannot commence without an assistant at his elbow, then his marching to and fro, ordering people out of the way, and "attitudinising," is delicious to witness. The sober judge is in direct contrast; he is neither grave nor gay, but keeps quietly plodding on in a steady systematic manner, keeping his thoughts to himself, giving his verdict firmly, and apparently not troubling himself about grumblers after he has done his duty, which all good judges seek to do.

There is just one other point—good judges have laboured long to make themselves efficient; their services are in great request, they travel oft and far, and according to their ability endeavour to do justice to all, even at the risk of not receiving justice themselves, for in not a few instances their fees are too small, and sometimes are not paid with the promptitude that is desirable. This, however, is not the rule, but so long as exceptions exist the system is faulty. It is always wise to obtain good judges and adequately remunerate them for their time and skill. Four first-rate men will do more work, and do it better, than twice the number of less experience and who have not given proof of possessing special qualifications for the work.

The exhibiting season is approaching its close, and the season for the consideration of future campaigns and their management will succeed. As one element that always demands attention is the judges and judging, these remarks on the subject may, therefore, not be inopportune; they are the outcome of much experience, and are written by—A VETERAN.

AUTUMN AND WINTER-FLOWERING PLANTS.

THIS season, especially the sunny weather of the past six weeks, has enabled cultivators of autumn and winter-flowering plants to have the wood thoroughly matured. Only moderate success can be expected in wet, cold, sunless seasons unless artificial heat is employed to supply the deficiency, and that is only a poor substitute for solar heat in the declining days of autumn. Those who practise giving heat to many plants that have to produce early flowers and assist them in the early season to make their growth, and then place them outside to thoroughly ripen and set their buds, reap advantages which cannot be produced by fire heat in autumn. This applies to early-flowering Rhododendrons, Deutzias, Prunuses, Azaleas of the Indica and Ghent types, as well as to Camellias and many others. To thoroughly prove the advantage of assisting plants to make an early growth, those who do not practise it can take a number of Deutzias and divide them into two batches, the one to be grown under the influence of heat, and the other plunged outside in pots, or planted out. The former will be a fine hazel colour and the foliage entirely gone, while the others will be green and only lose their leaves when compelled to do so after sharp frosts. It would quickly be seen which would produce their flower buds early when required to do so.

Cold nights are approaching, and it will not be safe much longer to leave such plants as Poinsettias, Euphorbias, and Plumbagos in cold frames, as if allowed to remain until checked much damage will be done, and the foliage of the Poinsettias will turn prematurely yellow and fall off. Plants of the above-named that were propagated late should be housed at once where a little assistance by fire heat can be given at night and during dull sunless days. Care must be taken not to excite the plants into fresh growth, but a rather dry atmosphere must be maintained, ventilating abundantly when favourable in order to bring growth to a standstill. Celosias will now be showing their plumes, and

must be assisted with a little fire heat at night, and sufficient ventilation to keep them dwarf and as stocky as possible. These useful plants are not grown for winter decoration nearly so much as they deserve; they will last fully four months for decoration in the conservatory during winter, and are invaluable for cutting and for associating with groups of plants for room decoration.

Epiphyllums are amongst the most lovely of winter-flowering plants, and where a succession of choice flowers are required they should be grown in numbers. They are of easy culture, and with ordinary care small plants can be flowered as well as those of larger size. They require heat and moisture while growing. Frequently they are insufficiently supplied with water, and have a hard struggle to exist. If still in heat and growth is completed, a cool temperature is of the greatest importance to harden their growth and ensure a regular head of bloom. At this stage a drier condition of the atmosphere and the soil is essential, but when required to bloom they must be introduced into stove heat. *Calanthes* and *Dendrobium nobile* must now be well exposed to the sun to mature their pseudo-bulbs, as upon this depends future success. Plants of the *Dendrobium* should be removed to a cool sunny position near the glass as soon as the growths are amber colour. Water will only be necessary in sufficient quantities to keep the growths from shrivelling.

Azaleas will be maturing their buds, and those of the *amœna* type and all early-flowering varieties must be kept cool for the present. Heaths of the softwooded type and *Epacris* will now be developing their bloom buds, and must not be permitted to suffer through insufficient supply of water. Ventilation must be liberal, and the plants protected from heavy rains. In dull damp weather they are very subject to mildew, which spreads quickly and soon disfigures the plants if its progress is not arrested. *Solanums*, *Salvias*, and *Callas* that are planted out should be lifted now and repotted in good loam, with a seventh of manure. They should be placed in a shady position until they recover, freely syringed and supplied with abundance of water. They can remain outside until the appearance of frost. Those most useful winter-flowering plants *Zonal Pelargoniums*, are in much finer condition and better ripened than they were last year. Their treatment for the present will consist in removing the flowers and liberally supplying the plants with liquid manure. The shoots should not be stopped after this date; in fact, stopping should have been discontinued some time ago.

Roses for early blooming will now need attention, as their growth will be matured and the foliage fallen off some varieties, such as *Gloire de Dijon* and *Lamarque*, that have been grown almost similarly to Vines in pots and trained under the roof of a plant house. When ripened as above indicated, it is wise to take the plants from under the roof and place them outside, which will prevent any of the buds starting into growth. After being outside and exposed to a few slight frosts they start into growth when introduced into heat with greater freedom. This is a good time to repot these Roses. The roots should be carefully uncoiled from the sides of the ball, and as much of the old exhausted soil removed as possible without much injury. They can be replaced in the same sized pot, and tied round four stakes placed near the sides of the pots, or trained in any shape according to the taste of the cultivator. It is far better to repot now than in the spring just after the plants have bloomed, which causes a severe check by interfering with the roots after they have commenced working. Hybrid Perpetuals that have been subject to forcing should also be repotted if they require it. It is a good plan to repot them every year before the foliage falls, they then become established before forcing time arrives.

Where *Clerodendron Balfourianum* is employed for early forcing, young plants should be annually grown for the purpose and trained under the roof of plant stoves until ripe, which is preferable to training them round stakes, thus hiding the wood from light and air by their own foliage. If ripe they can now be taken down and trained round stakes and placed in a cooler position, giving them less water at the roots. It is necessary to mention here that *Clerodendrons* require a minimum temperature of 50° to 55°. The cuttings are obtained as early in the year as possible from young shoots when a few inches in length, they are inserted singly in pots and placed in the propagating pit or frame. They quickly produce roots and are potted-on afterwards as they require it in a compost of loam and peat equal parts, and plenty of coarse sand. They are grown in 6, 7, and 8-inch pots. The smallest are useful for room or table decoration. If intending cultivators have not an early plant from which to obtain cuttings, it is a good plan to employ the wood that is ripened now, which strikes as readily as the young shoots if cut off below a joint, a pair of leaves being retained. The cuttings can be inserted round the sides of a 5-inch pot, or singly in small pots. The young plants

should be kept slowly growing through the winter. This allows cultivators with moderate accommodation a long season in which to produce satisfactory plants.—WM. BARDNEY.

THE SCOTCH CHAMPION POTATO.

I WAS pleased to see the remarks of Mr. John Taylor in your last issue relative to the qualities of this Potato; for though Mr. Beachey has a long list of complaints against it, and Mr. Luckhurst thinks it far below the standard of a really good Potato, most of those who have grown the Champion and thoroughly tested it will continue to do so until something better is provided. That it has some objectionable qualities I admit, one being its length of haulm, which renders it unfit for small gardens because it takes up so much room, another its deep eyes; but these objections are insignificant when compared with its good qualities. Two acres of Champions have been grown on the farm here for five years, and they have never failed to produce a heavy crop of good tubers. Some years the disease shows itself amongst them, but never to do much damage; whilst other varieties, such as *Snowflake*, *Early Rose*, and others, are destroyed with it. As to quality, we never have any complaint on that score after we begin the Champions, which is as soon as they are large enough. We have already begun using them this year, but they have not yet obtained their full size. No wonder Mr. Beachey complains of a poor crop when he talks of cutting the tops off and taking up the tubers in August. When cooked they are white and mealy. Mr. Beachey must either have a bad cook or he has not the right Potato, for whether baked or boiled they are always good. There is no need to peel them if a cut or two is made through the skin, thus avoiding the waste that would occur by cutting out the deep eyes.—A. BARKER, *Hindlip*.

MORE ABOUT VIOLETS.

SINCE I last sent you an account of *Violet Argenteaflora* in June and July I have gathered about a hundred blooms every second day from three dozen plants, and still they are being produced. The principal part of the flowers have been produced from the runners, and now the crowns of the plants and the runners are showing flowers plentifully, so that I hope for a full harvest of blooms through the winter. The flowers are not large as Mr. Beachey remarks, and have not the substance of *Victoria Regina*, but they have capital footstalks, admitting of their being made up into bunches 6 inches in diameter, which is unattainable with any other of the small-flowered single varieties. Bouquets of this size have a very elegant appearance and are much appreciated, not the least of their merits being the neat foliage and delicious scent.

Victoria Regina commenced flowering early in August, but it was not until September 3rd that the blooms were abundant. This is a very useful Violet, and unrivalled in purples. In contrast with *Argenteaflora* the effect is pleasing. Here on the north-east coast, over three hundred miles further north than Mr. Beachey, and 540 feet above the sea level, it is necessary to plant in frames to ensure the free flowering of single as well as double Violets in autumn and onwards.

De Parme was gathered for bunching at the same date as *Victoria Regina*, but from its shorter footstalks cannot be made up into bunches of more than 4 inches in diameter, the doubles not being so readily bunched as the singles. *New York* (*odorata pendula*) also was gathered on September 3rd, it and *De Parme* being very similar in foliage and colour. *New York* is a deeper mauve colour with a partially red and white eye, *De Parme* having a white centre. Both are very sweet and beautiful. All the Neapolitan Violets have a tendency to lose the centre growths or crown, which can only be obviated by planting fresh-rooted runners or suckers in spring, and not allowing them to produce offsets during the summer. Double Violets last twice as long in water as the singles.

Prince Consort showed its first blooms on September 9th, but it is not good until October, when it gives flowers one-half larger than *Victoria Regina*, and of a paler or bluish purple. It has splendid foliage, fine rounded petals, and is the finest in form of any. It is not so free to produce runners as many, being in every respect the prince of Violets.

Princess of Prussia is an intense purple, very glossy; flowers of great substance, petals well rounded, and very sweet. Plant not so vigorous as *Victoria Regina*, sparse in foliage as compared with that variety, but forms very full crowns from which spring noble flowers. It evidently is a grand autumn bloomer if not the best, and runners are very sparsely produced. I had the blooms of a lovely soft rose Violet sent me in spring by Mr. Lee, and a more beautiful associate for blue and white Violets it were not possible

to conceive. It was single, had long footstalks, and was very sweet. If it proves equal to promise it will be an acquisition.

To have Violets in pots no plan is better than now to pot rooted runners of the current year, placing them as thickly as possible with some soil between them, in 4 to 6-inch pots, employing thoroughly decayed manure or partially decayed leaf soil and loam in equal parts, potting not very firmly, and placing the pots on ashes in a cold frame. Keep the frame rather close and shaded from bright sun for a few days, then ventilate freely, and never allow the plants to suffer by want of water. Remove them to a house early in November with a temperature of 40° to 45° artificially, and they will bloom all the winter, being very useful for decoration. They should be supplied with liquid manure not too strong, and be kept near to the glass.—G. ABBEY.

NEWCASTLE HORTICULTURAL AND FLORAL SOCIETY.

THE immense popularity the above great northern Show has attained to was more strikingly exemplified in the present Exhibition than in any of its predecessors. The weather was quite the reverse of favourable, but we learn that the financial results will not be far behind those of last year, which is no doubt due to the judicious issue of tickets and the advantages of cheap membership. It would be no easy task to particularise the most important feature of the Exhibition, as in each department there were exhibits of superior merit. The Judges, nearly all south countrymen, were unanimous in expressing their opinion that as a provincial Show it stands among the foremost. The Grapes were fine and in enormous quantities. Gladioli, Dahlias, and Hollyhocks were numerous; indeed it was considered that the latter were never shown to better advantage.

To note the exhibits according to the arrangement of the schedule we commence with the table decorations. For the best table the Society offered £10. This prize is generally strongly competed for at Newcastle. Lindsay Wood, Esq., South Hill (Mr. Thompson), was first with a light and elegant table in his usual admirable and successful style. Messrs. Gellender & Sons, fruiterers, Newcastle, were second with a good arrangement. The centrepiece was especially noteworthy; it consisted of choice flowers of white Camellias, Allamandas, and towards the base were coloured flowers, such as Vallotas and Roses. E. Lange, Esq., Heathfield House, Low Fell, Gateshead (Mr. Methven), was third with an excellent table—a marked improvement on his former attempts. This award did not meet with general approval, as many good judges thought Mr. Methven entitled to the second place, and desired to know what points had led to the decision. Table plants were shown in good numbers. Capt. Bell, Wolsington (Mr. Thompson), was first with *Dracæna australis*, *Croton irregularis*, *Dracæna regina*, *Aralia elegantissima*, *Cocos Weddelliana*, and *Pandanus Veitchii*, all of which were rather large. Many excellent stands of choice though smaller plants were passed. Some of the baskets were very good, but many of them were disqualified owing to their not being in strict accordance with the terms of the schedule. For the best epergne Mr. Ison, Tower Street, Sunderland, was first in the open class. In the corresponding gardeners' class E. Walker, Esq., Shot Tower, Newcastle (Mr. Whiting), was first with creditable arrangements. There were sixteen bridal bouquets, many possessing considerable excellence. Mr. Jackson, nurseryman, Blakedown, Kidderminster, was first with a neat arrangement of white *Lapagerias*, *Stephanotis*, *Campanula alba*, and double white *Primulas*. Mr. Cramont, Sunderland, was second; Miss Hughill, Sunderland, winning in the corresponding or gentleman's gardeners' class. In the open class nineteen hand bouquets were shown; amongst these Mr. R. Pattinson, St. Ann's Hill Nursery, Carlisle, was first with a bright arrangement of *Tuberoses*, *Ixoras*, *Cattleyas*, and other flowers. In the other class Mrs. Cramont was first with a bouquet in which *Salvia patens* was effectively employed.

The cut flowers formed the principal attraction of this great Show. Dahlias were superb; no less than seventeen collections of twenty-four blooms each were staged. Mr. H. Clark, Rodley, near Leeds, was first in that class with excellent flowers of good size but not coarse; the best being *Prince Bismarck*, *Ethel Britton*, *Barnaby Rudge*, *H. Walton*, *James Cocker*, *Constancy*, *Clara*, *George Smith*, *Royal Queen*, *Mrs. C. Reid*, *Lord Chelmsford*, *Willie Eckford*, *Criterion*, *Miss Proud*, *John Neville Keynes*, *John Standish*, *Mrs. Harris*, *James Service*, *Toison d'Or*, *John Greenaway*, and *Charles Wyatt*. Mr. J. W. Boston, Cawthorpe, Bedale, Yorkshire, was second also with fine flowers. Mr. E. Fletcher, Charlestown, Bailton, near Leeds, was an excellent third; Mr. J. Walker, Low Fell, and Mr. R. Harkness, Allendale, following. Amongst the remaining stands were to be found many excellent flowers. For twelve fancy varieties there were thirteen exhibitors, Mr. H. Clark being also first in this class; Mr. J. Painter, Smallwood, Stoke-on-Trent, was second; and Mr. C. Rylance, nurseryman, Aughton, Ormskirk, Lancashire, third. In the winning stand were good flowers of *Gaiety*, *George Barnes*, *Rev. J. B. M. Camm*, *Attraction*, *Grand Duchess*, and *Octoroon*. In the corresponding class for twelve Dahlias there was strong competition. Amongst twenty-six competitors Mr.

Walker, Low Fell, Gateshead, was first; a successful local exhibitor, Mr. Oliver, gardener to the Earl of Ravensworth, Easington Park, was second with a good stand containing a new *Dahlia*, Earl of Ravensworth, of good shape and of a lilac colour. A certificate of merit was awarded.

For twenty-four Hollyhocks Mr. J. Thompson, nurseryman, Newcastle, was first. The flowers were very large, averaging quite 5 inches in height and diameter. This fine collection was greatly admired. Mr. G. Rogerson, North Middleton, was second; Mr. Sanderson, Whalton, third. Gladioli were also good and in great numbers; Mr. J. Gray, Newfield, Kilmarnock, being first with fine spikes neatly staged of *Horace Vernet*, *Grand Lilas*, *Orpheus*, *Le Phare*, *Camille Benvenuto*, and *La Vesuve*. Mr. J. Fenwick, Netherwitten, was second with spikes of nearly equal merit. Mr. G. Charlton, Morpeth, was third. For nine spikes in the corresponding class Mr. W. Davy was first, and Mr. G. Rogerson second. Roses for the lateness of the season were fine. Messrs. Mack & Son, nurserymen, Catterick, Yorkshire, were first with large and fresh blooms; Mr. Hawkin, Woboston, being second, and Mr. W. G. Watson, The Hall Nurseries, Fenham, Newcastle, third. Eleven collections were staged. Asters were admired by all. Mr. W. Spoor, Swalwell, was the most successful in the class for Globe varieties, which were very large and fine; Mr. G. Rogerson taking the chief prize for feathered varieties. Carnations and Picotees were also in fair condition. Pansies and Marigolds were numerous, the latter of extraordinary size. Collections of stove and greenhouse flowers were no exception to the rule, for they were both numerous and good. T. Fry, Esq., Woodhouse (Mr. J. Noble), was first with good bunches of *Ixora affinis*, *Allamanda Hendersoni*, *Bougainvillea glabra*, *Dipladenia Bicarleyana*, and *Lapageria rosea*. Wild flowers were an additional feature; Messrs. Hunter and Battensby taking premier honours with good collections, representing nearly all the flora of the district.

The fruit was of superior quality, the Grapes being among the best that have been shown at any exhibition this year. For a collection of eight dishes of fruit the Society offered £6 as the first prize, and the President, G. A. Fenwick, Esq., gave a silver cup. The Duke of Northumberland, Alnwick Castle (Mr. A. Ingram), was first, his best dishes being a good *Queen Pine Apple*, two fine bunches of *Black Hamburgh Grapes*, large in berry and finely coloured, and excellent bunches of *Muscat of Alexandria Grapes* weighing nearly 5 lbs.; *Barrington Peaches*, *Moorpark Apricots*, a grand *Colston Bassett Melon*, *Coe's Golden Drop Plums*, and late *Duke Cherries*. The Duke of Cleveland, Raby Castle (Mr. Westcott), was second with a good *Queen Pine*, *Black Hamburgh* and *Muscat of Alexandria Grapes*, fine *Princess of Wales Peaches*, *Red Roman Nectarines*, and *Moorpark Apricots*. Mr. H. A. Mann was third. Mrs. Pease, Southend, Darlington (Mr. Neil Black), had a collection including an excellent *Queen Pine* which weighed nearly 5 lbs. Collections of hardy fruits were excellent; Mr. Ingram and Miss Surtees, Hamsterley Hall (Mr. Grice), took the chief honours. The competition for six bunches of Grapes was very keen, there being eleven entries. Sir Wilfrid Lawson, Bart., Brayton Manor, Carlisle (Mr. Hammond), was an admirable first with excellent bunches of *Black Alicante* well finished, *Muscat of Alexandria* well coloured, and two good bunches of *Mrs. Pince's Black Muscat*; Mr. Ingram followed with the same varieties in similar condition. Messrs. Laidlaw, Henson, and Westcott secured the other prizes. For two bunches of *Black Hamburghs* Messrs. Westcott, Cramont, and Laidlaw were first, second, and third respectively with excellent examples. For two bunches of *Black Alicante* Mr. Hammond was again first, Messrs. Ingram and Westcott following. For black Grapes of any other variety Mr. D. P. Bell, Clive House, Alnwick, was first with his noted *Alnwick Seedling*, Mr. Ingram following with *Mrs. Pince's Black Muscat*. For *Muscats* Messrs. Ingram, Shaw, and Hammond were the winners. For *Buckland Sweetwater Grapes*, and the heaviest bunch, Messrs. Laidlaw and Hammond were respectively successful. Seven dishes of *Peaches* were shown and three of *Nectarines*. Dr. Murray, Jesmond (Mr. Russel), and Mrs. Vincent, Grantham (Mr. H. A. Mann), were the winners; Mr. J. Noble winning in the class for *Apricots* with the *Gros Pêche*. The hardy fruit was abundant and fairly good. There were nine dishes of dessert Apples, Mr. C. Rylance being first with the varieties *Lemon Pippin*, *Duchess of Edinburgh*, *Irish Peach*, and *Lady Derby*. The same exhibitor was also first with culinary Apples, which were of good large size and form, and consisted of *Lord Suffield*, *Rylance Surprise*, *Grenadier*, and *King of Apples*. Plums were also numerous.

Among the exhibits that were not for competition were collections of skeleton leaves, dried by Mrs. Hodgkins, Hyde Grove, Manchester, Messrs. W. J. Watson, Fenham; Fell & Co., Hexham; Robson & Son, Hexham; Clark Bros., Carlisle; J. Thompson & Son, Newcastle; and W. R. Armstrong, Newcastle, contributed excellent collections of plants, consisting principally of *Coniferae*, alpine, and hardy plants, which added considerably to the adornment of the Show. The members of the Committee forming the executive were present all the time at their respective posts, conducting the arrangements with courteous business tact. The Secretary, Mr. Gillespie, and the acting Vice-President, Mr. Garrett, also by their efforts contributed largely to the success of the Exhibition.

GLADIOLUSES CLEOPATRA AND MARGUERITA.—Of the many good varieties noticed during a recent visit to Rose Hill Gardens,

Sligo, these deserve special commendation. The one is a fine fresh rose colour tinted with lilac, with large and effective flowers and broad shaded lines, the spikes being unusually long. The other an enormous flower, white, rose, and cerise, with dark carmine spots and beautifully softly shaded throat. Each of these had upwards of twenty flowers to each spike and very open. —W. J. M., *Clonmel*.

APPLE BENONI.

FRUIT below medium size, oblato-cylindrical, even and regular in its outline except at the crown, where it is somewhat undulating, and generally higher on one side than the other. Skin when fully ripe of a rich yellow colour, with a crimson cheek where exposed to the sun, and marked with short broken streaks of darker crimson; here and there, especially towards the apex, there are patches of russet. Eye closed, with flat segments, which overlap each other, and set in rather deep and irregular cavity; tube long, funnel-shaped; stamens median; stalk from a quarter to half an inch long, very slender, and deeply inserted in a round cavity. Flesh yellow, very tender and delicate in tissue, sweet and briskly flavoured, and with a remarkably high perfume, like that of a Pine Apple, which is very characteristic of this Apple when it is highly ripened. Cells of the core closed.

This delicious Apple for the dessert ripens in September. It is a

Fig. 55.

native of the United States, where it originated at Dedham in Massachusetts. There it ripens in August, and the colour is described as being of a "deep red." It was introduced to this country by Mr. Rivers of Sawbridgeworth, to whom we are indebted for the specimen from which this figure and description are taken. Some of the fruit we received from Mr. Rivers were grown on a tree in a pot out of doors, and these were a brilliant golden yellow, and the flavour and perfume superb; the others, which were from a bush tree in the open ground, were in accord with the description given above, but had not the exquisite flavour and aroma of those grown on the pot tree. Mr. Rivers says, "I have little pyramids covered with fruit, which were ripened before this time (September 16th) last year." This Apple ought to be in every garden.

THE CHRYSANTHEMUM FOR EXHIBITION AND CONSERVATORY DECORATION.

SOON a scarcity of flowers will be felt, and where flowers are required in quantity there are no plants that supply this desideratum through the dreary months of November and December so well as a few dozen plants of large-flowering and Pompon Chrysanthemums. Where these plants have received moderate attention in affording them copious supplies of water, securing their growths to sticks and tying to prevent breakages by wind, no anxiety need be felt as to results.

Cuttings struck last November or early in the spring should have been potted-on in a compost of good stiff yellow loam, with a liberal admixture of well-decayed manure and sharp sand. Three shifts for large-flowering varieties and three stoppings will

be found quite sufficient, the last shift being into a 10 or 11-inch pot, which size will be large enough for plants to produce from forty to sixty good blooms. Where quality is desired, forty of the strongest shoots should be selected, and all the buds from the remainder removed. These blank shoots can be utilised when training commences to supply foliage to the base of the plants.

Large-flowering Chrysanthemums ought not to have been stopped after the middle of June, and Pompons not later than the first week in July, bearing in mind that well-ripened wood produces good quality flowers. Plants growing freely will require weak liquid manure, frequently commencing the application about a fortnight after the last potting. Soot water is a good stimulant, and imparts a healthy green colour to the foliage. Weak guano water can be substituted, say twice a week, from the middle of October, with advantage to the flowers (but not to the foliage) until they show colour.

Plants that have received the above treatment during the spring and summer months have by this time nearly, or quite, completed their growth. All the early large-flowering varieties intended for public exhibition or otherwise, if not already disbudded, should be attended to without delay. The late varieties will be coming in fast now, and will require attention. The operation of disbudding is simply removing all buds except the centre one, leaving one bud to each shoot, the object being to concentrate the strength of the shoot in one flower. The bush form of training is the best for large varieties. Until the first week in October no training is necessary, except inclining the breaks from the first and stopping them in a downward direction. Sticks 2 feet long, and painted green, will be found very suitable. Some twisting will be required to bring each bud on the top of the stick.

Pompon standards are very useful and beautiful. The only difference in treatment is that the cutting must be allowed to grow to the desired height before stopping, a small wire hoop must be placed round the head, and the branches tied down occasionally. A few of the weakest buds should be taken out as recommended for large varieties, but not to such an extent. —W. H., *Tulse Hill*.

POTATO SELECTION.

So much has been written on the Potato and its disease in the Journal for the last few weeks both practically and theoretically, that, if the subject was not of so much importance to the community generally, there would seem little need for further notes on this matter.

Selection of seed, of site for planting, and of manures, do undoubtedly in a measure tend to reduce the virulence of the disease, but I venture to think that above all we must make a selection of the varieties grown. The notes on Potatoes on page 251 of the *Journal of Horticulture*, by Mr. Muir, contain to my mind information from which much benefit may be derived by those who cannot advantageously carry on experiments for selection purposes on a large scale themselves, especially when those notes are the outcome of repeated trials extending over years when the disease has been exceptionally bad. Mr. Muir, at least, is not one of those "ordinary gardeners" who are said to fold their hands and submit to fate with the apathy of Orientals. I remember with what interest I was shown last summer his extensive plots of trial Potatoes, where not only was there the great number of varieties mentioned by him, but experiments were being conducted on some varieties with different forms of artificial and natural manures.

In the selection of Potatoes the least trouble will be found with those for early use, as the first-crop Potatoes can generally be lifted before the disease sets in. To those mentioned by your correspondent I should like to add Rector of Woodstock, as it is so good in quality at an early stage of growth that it need scarcely be left in the ground after the tubers are of fit size for use, for unfortunately it is very subject to disease, and can only be recommended for use as a first early.

In the selection of a midseason Potato there is more difficulty, and the only one that resists disease well with me is the Schoolmaster. I usually save my main crop of Potatoes by pulling off the tops on the first symptoms of disease, but I am in the habit of leaving a row of each variety with the tops on; and I find that while the rows thus left were utterly worthless in the case of Snowflake, Rector, &c., and much diseased in Porter's Excelsior, International Kidney, Yorkshire Hero, and others, the row left unpulled of the Schoolmaster not only remained good, but the Potatoes had increased much in size, and the crop would be quite one-third heavier than in the rows from which the tops were removed. This immunity results probably from the same cause as that to which is attributed the greater disease-resisting powers of Champion and Magnum Bonum—viz., hard texture of stems. I have

no hesitation in supporting Mr. Muir's recommendation of Schoolmaster, and in advising its use for a main garden crop. I fear we must be dependant on a field supply of Champion and Magnum Bonum for the latest supply, for they are certainly too rank in growth for an ordinary garden.

Each season I have been obliged to give up the cultivation of some late varieties through disease, and if compelled to grow only three sorts would plant Rivers' Royal Ashleaf or a kidney of that type, Schoolmaster, and Magnum Bonum; the last in a field if convenient.—R. CROSSLING.

IF Mr. John Taylor will only procure a really good strain of Paterson's Victoria he will find it to possess most if not all the high qualities enumerated by me. The very best form of it that I have met with is the Dunbar Victoria of commerce, every tuber supplied by Potato dealers being exceptionally large, full eyed, and of the true flat kidney-shaped type. The old tubers are still excellent in June, and you may dig up the young tubers as soon as they are large enough for cooking in July, and they will prove so white, mealy, and well flavoured as to obtain the especial approval of those who are critical in such matters, and I suppose we are all so in some degree. Let not the failure of this and most other good varieties last year induce us to give undue preponderance to the one or two points of merit in rampant-growing Champions and Magnum Bonums. Unfortunate indeed must be those persons with whom it is "a question of Champions or no Potatoes" again this year. That it unfortunately is so I have strong reason to believe from the account I have received of water laying for weeks in the furrows between the rows in some districts. Under such circumstances the stronger-growing sorts could alone flourish, and I suppose it is this fact which prompts so many to regard them as superior to more delicate varieties.—EDWARD LUCKHURST.

PETASITES FRAGRANS.

WINTER-FLOWERING plants are always valuable and scarce, and in the Petasites fragrans (sometimes known as Tussilago fragrans) we have a midwinter flowering perennial. The flowers are whitish, with a peculiar Heliotrope-like perfume, and are borne in a thyriform panicle. It can be grown almost anywhere, such as under the benches of greenhouses, in a cold frame, or even out of doors with a slight protection from frost. It was introduced from Italy about the year 1806, and has become so well naturalised in some parts, and especially in Cornwall, as to become a troublesome weed. I think it is best to grow this plant in boxes. Its common name is the Winter Heliotrope.—W. R.

FUNGI A CAUSE OF DISEASE IN PLANTS.

"WHY," writes Mr. Luckhurst in your last issue, "does 'S.' entertain feelings of regret that our opinions are entirely at variance?" My reply to this query is that I suppose it is due to the fact, well known to all, that when a man of whose general accuracy of judgment we were previously assured expresses an opinion opposed to our own, it suggests either that his observations are not reliable, or the equally unpleasant alternative that we have ourselves been mistaken. This was my predicament when I read Mr. Luckhurst's first communication on the subject under discussion, and it induced me to request him to state his reasons for such positive assertions, fully expecting in reply facts that would substantiate his views and subvert mine. In this, however, he has not been very successful, for with one exception we were already familiar with what is advanced; and in my opinion it affords very dubious support to his statements. Taking these in the order he discusses them, the first to be considered is

The Potato Disease.—Under this head your correspondent commences with a question to which he gives an extraordinary answer. "When are fungi perceptible in the Potato? Before the plague spot appears, or afterwards? Invariably afterwards." If this be correct the matter is quite clear and indisputable; but upon what is it founded? If Mr. Luckhurst has microscopically examined the tissue of the Potato with the care and perseverance needed in such work, and has conclusively proved that when the "plague spot" appears there is no trace of fungus spores or mycelium in plant or tuber, then he is entitled to great credit for a discovery of considerable value very modestly announced. If it is not derived from his own observations who is his authority? I have never seen the statement in any of the multitudinous treatises that have appeared upon the subject in recent years. But possibly much depends upon the interpretation of the word "perceptible" in the first sentence quoted; for if this is only intended to signify what can be seen by the unaided vision, it possibly applies to the appearance of the fructification of the fungus on the surface of

the plant, in which case I fail to see how it supports the argument that fungus is a result of disease. This portion of Mr. Luckhurst's reply requires further elucidation, which undoubtedly he will willingly supply. As to the fungus continuing to spread, "no matter how hot or dry the weather may be," I can only say that it is directly contrary to my experience, for hot dry weather most decidedly arrests its progress, and elaborate statistics have been published showing that heat and moisture are its chief requirements. It appears to me unnecessary to seek imaginary causes of disease when those already known are sufficient to account for the phenomena. The Potato fungus is known to poison and corrode the tissue of the plant into which it penetrates, inducing decomposition by a positive action upon the living substance, where its mycelium is traced, and there only are the peculiar characteristics of the Potato disease found. Why was the disease we are familiar with unknown in this kingdom previously to 1845? Why was the *Peronospora infestans* then first observed here, though it had been previously known in America? And if the Potato disease is not the effect of a fungus, what is it? Can Mr. Luckhurst answer these questions satisfactorily? As to the experiments with Salus at Chiswick, they were simply undertaken to ascertain if it possessed any efficacy in preventing the disease; but their success or failure had no bearing upon the relation of the fungus to the disease.

Peach Blister.—A few years ago this subject was discussed at length in the pages of the Journal, but the only evidence adduced in support of the view that the blister is not the result of a fungus attacking the foliage was the generally admitted fact that it is confined to trees occupying exposed positions. This is all that Mr. Luckhurst now advances, and yet it is by no means sufficient to satisfy an unprejudiced mind that his view is correct. In the first place the cold winds, which are alone said to give rise to the blister, do not, so far as my observations go, produce a similar effect on any other inhabitant of our gardens. The tendency of exposure to winds is to cause the foliage to shrivel in the majority of plants, and not to become inflated or blistered, which generally results from internal injury, as in the case of many leaf-burrowing insects. Secondly, the conditions which are claimed to produce the blister are exactly those that favour the production of the fungus, for at no other time does it appear; and this fact, so far from confirming your correspondent's opinion, is directly opposed to it, as if unhealthiness of a Peach tree was all that is needed to render it a suitable habitation for the *Ascomyces deformans* it would surely appear at other seasons, when the moisture and temperature are such as encourage the growth of fungi generally. It must, however, be remembered that fungi are very widely distributed, members of the order occurring in all parts of the world even where the cold is excessive, and many will only thrive when a particular temperature or moisture peculiar to the species or genus is provided. Again, whenever the blistered leaves of the Peach have been carefully examined by competent observers the tissues have been found to contain the mycelium of the fungus, and it is incumbent upon those who oppose the opinion that the blister is produced by the fungus to prove that they have similarly examined leaves in which no trace was present.

Concerning the shanking of Grapes I have little to say. My opinions on the subject have hitherto been in accordance with the overcropping or exhaustion theory, and I should require some substantial evidence to induce me to alter my views. Mr. Harrison Weir is, I believe, the first writer who has advanced the theory that shanking is due to a fungus, and at present his statements have not been confirmed by any other observer.

With regard to the remarks concerning the analogy between plants and animals, Mr. Luckhurst should remember that it is only in the lowest forms that the two kingdoms approach each other. The most highly organised are widely different in structure and requirements, yet it was from the latter that he endeavoured to deduce his argument; the analogy between a man and the Potato plant, for example, is not very striking. His argument in logical form was this: Delicate human beings are more subject to infectious diseases than those that are healthy; plants are analogous to animals; therefore an unhealthy Potato plant is more liable to be affected by the fungus *Peronospora infestans* than a healthy plant. The first proposition is inaccurate, and consequently the conclusion is illogical. Then the statement that "similar conditions are necessary to health" of both the plants and animals is scarcely correct. Plants possess the power of converting various elements and chemical compounds into organised substance, animals can only assimilate that which has already been prepared either by vegetables or other animals; plants chiefly require carbonic acid gas in the atmosphere, animals need oxygen; plants can live where animals would speedily die; and further, the most luxuriant vegetation on the face of the earth

occurs where the heat is greatest in combination with abundance of moisture, both of which in the extreme are adverse to the health of all except the lower forms of the animal kingdom.—S.

RUBUS ROSÆFOLIUS CORONARIUS.

In reply to a correspondent who desires information concerning this plant, we are enabled, by the kindness of Messrs. Veitch and Sons of Chelsea, to give the accompanying illustration of a really beautiful and useful plant. The flowers are very double, pure white, and of neat form, and being produced during winter and spring they are of considerable value wherever flowers are in demand; moreover, the leaves are very elegant, being pinnately divided, the pinnæ small, acute, and dark green. The plant is compact in habit, and well suited for culture in pots in any cool house, particularly a greenhouse, where it succeeds with but little attention. A moderately rich compost of loam, sand, and leaf soil with a small proportion of well-decayed manure suits the plant admirably.

Both the species and the variety are stated by Paxton to be natives of Mauritius, but later writers consider the Himalayas as the chief locality where the plants occur in a wild state. They have now been in this country about seventy years, and it is surprising that such attractive plants should have been so long neglected.

STOKING.

Now that the dull short days and cold long nights will soon be here again, boilers, hot-water pipes, flues, stokeholes, and stoking will require attention, and the most important of all, in my opinion, is the stoking. Many different shaped boilers, various sized pipes, and many kinds of flues will all produce heat, but whether that heat be much or little, produced with economy or extravagance, all depends on the person who has to attend to the fire. So far as my experience goes, there is nothing more troublesome than to induce young men to attend to the fires properly. One will continually have the fires so low that they are always half out; others will persist in throwing large quantities of coal on whenever the fires are looked to, regardless whether that which was put on previously is burned down or not. This is a very common and most extravagant way of firing, because much coal is wasted, but there is little obtained from it, as a mass of smouldering black coal never does emit much heat. Another way is to fill up the fireplace with as much coal as it will hold, and not look at it again until the whole has burned down. This is a good way to save labour; but for economy in coal, steadiness in heating, and satisfactory results in every way, this system can never be carried on with success.

Nothing will give a gardener or employer more satisfaction than seeing the fires well attended, and when once a person takes an interest in it the whole is easily done. When the fires are used constantly the ashpits should be cleaned out daily. An old man or boy is employed in many gardens to do this work as well as to take in the coal. Those making gardening a profession need not be expected to do this except when there is no one else to do it—when a fire is only lighted for a night or two on the occasion of a little frost, &c., and then allowed to go out for days or weeks afterwards. Cleaning the place out thoroughly should not be left until the fire is needed again, as this generally leads to much confusion.

Cleanliness should always be one of the leading orders in the stokehole. Coals and ashes mixed together and covering every inch of the floor indicates much carelessness and waste, besides adding to the work of the fireman and detracting from his comfort. The floor should be clean, ashes and coal in their proper places, and all in good working order. Stokeholes are often associated with dust and dirt, but it is only by allowing these to accumulate that anything of the kind becomes troublesome, and in a tidy stokehole any one might stir up the fire or throw on coal without making more dust than comes from any ordinary kitchen range. One of the principal matters to be done to insure good firing is always to keep the fireplace clear of exhausted fuel. A heap of clinkers at one side and a large quantity of black ashes at the back will most effectually stop the fire from burning well and cause a deficiency of heat; this is always found in bad-managed

fires, a little clear spot inside the door being all the means left to drive the fire. Coals are thrown on to such a fire, but they are never properly consumed. Small red fires produce the most heat. When a fire is half burned down many throw more coal on it—a very bad plan, as in this way a great quantity of coals are used and little heat produced.

When a fire is started any time during the day, do not heap it up as if it was not to be looked to again for a week, but put on a small quantity and let this burn well down into a glowing mass before more coal is added. Using a large quantity of coal is by no means a sure sign that much heat is being produced; very often it proves the reverse. During warm days and cold nights the fires should be cleaned out in the morning as usual, then put on a

Fig. 56.—*Rubus rosæfolius coronarius*.

fair quantity of coal, the large pieces at the bottom and the smaller on the top; close the ashpit door, and lower the smoke or chimney damper, and everything will remain safe until the afternoon. When the fire is started again it is only necessary to break up the coal placed on in the morning with the poker, and a good fire will be the immediate result. No more coal should be put on then until the heat is well up and the fire well burned down. When the fire chances to burn very low, placing a large quantity of coal on it will effectually prevent the heat from rising for a long time, but if only one or two shovelfuls are put on it will burn up quickly. These appear small details but they are of great importance, as it is by neglecting these small matters that a good system is spoiled. When the fires are attended the last thing at night more coal has generally to be put on than is used at any other one time, but those who take an interest in their fires soon find out what quantity of coal will last for so many hours and work accordingly. In windy weather fires burn much quicker than at other times, but they can always be regulated by the ashpit door or damper. The number of times to attend to fires during the day or evening must be ruled by the heat to be

obtained, the weather, and other circumstances.—A KITCHEN GARDENER.

LOBELIAS.

BLUE and other dwarf Lobelias are such general favourites that no flower garden, however small, can be satisfactorily furnished without them. As edgings for beds, lines, vases, and window boxes they are indispensable, while a patch here and there near the front of a mixed border not only does not appear out of place, but imparts cheerfulness and completeness to the general arrangement. The present is the period for providing a stock of these attractive flowers; and fortunately the work is easy, and the necessary plants, even for a very large garden, occupy but little room during winter, and require little heat. A shelf near the glass in a light greenhouse is the only convenience required, while the attention the plants need to preserve them is of the slightest.

It is generally conceded that the plants are best propagated by cuttings; indeed this, or divisions of some of the dense growers, are the only modes of keeping the varieties true. When, however, a large number of Lobelias are required for long lines in the front of shrubbery borders or for mixed beds, raising the plants from seed is the quickest, easiest, and most convenient mode, while the results are usually satisfactory. For panels and lines, where great exactitude in the heights and habits of the plants is important, seedlings must not be relied on, for even if the seed has been saved from plants raised from cuttings there will be several plants varying more or less from the original, and which would mar the effect of a small geometrical arrangement; but this little diversity is not in the slightest degree obtrusive in the long lines above noticed, and in mixed borders.

As is generally understood plants raised from cuttings are the best from which to save seed, for there is then less deviation in the habits and colours of the plants resultant than of those the produce of seed saved indiscriminately from seedling plants. Yet if seed is saved from seedling plants indiscriminately instead of indiscriminately a valuable strain of Lobelias may be perpetuated. For seed-raising a row of plants should be grown in a warm, sunny, and rather dry position, and as soon as the plants flower all that are faulty in habit or colour should be pulled up, and those remaining will be almost if not quite equal as parents to plants raised from cuttings. I can point in proof of this assertion to some hundreds of yards of Lobelias, the plants of which have been thus perpetuated by seed for more than twenty years, and with the display no fault can be found, for the lines are true, level, and uniform in colour.

For general purposes in long borders and large beds the old Lobelia *Erinus speciosa* is not yet surpassed, if equalled. For raising plants that will be of good size in May the seed is usually sown in February, the plants being grown on in heat for two months, then duly hardened off. It is, however, often much better to sow the seed in September, wintering the plants in the seed pans or boxes on a greenhouse shelf. They there grow steadily all the winter, are hardy in character, and ready for pricking off in the earliest days of spring. This is the plan *par excellence* for amateurs who only possess a greenhouse, with perhaps a frame or two to aid them in preparing plants for their flower gardens. The seed should be now sown without a day's unnecessary delay in pans or boxes of rich light soil, which must be kept constantly moist. A cool, moist, shaded frame is a suitable position for raising the seedlings.

When the stock of Lobelias is raised from cuttings there are three modes in which stock plants are provided:—1, By potting a few small plants in the spring and plunging them in ashes in the open ground, cutting off the flowers two or three times during the summer to induce a mass of healthy growth. These plants, if grown in 5-inch pots and shifted in February into pots a size or two larger, produce an abundance of fine cuttings for propagating purposes. If all the cuttings are not wanted the plants flower profusely in May, and are most valuable for conservatory decoration. 2, By taking cuttings now from the base of the plants, inserting them in sandy soil, and striking in a close frame. These pots of young plants placed in heat in spring afford a plentiful supply of fine cuttings. It is, however, sometimes difficult to find good cuttings now for insertion, and the best mode of insuring them is by partially cutting down a portion of the plants in August. 3, By taking up a few old plants from the beds in the autumn and establishing them in pots. For this purpose, it may be added, the plants are much better if the flowering parts are cut off a month before the plants are potted. They must be potted in light soil to induce quick root-action, and no position is better for them than the north side of a wall in the open air until frost approaches, when they must be placed in a cold frame,

from thence when severe weather is imminent transferred to the greenhouse. These modes of establishing stock plants apply to all the free yet compact forms of the *Erinus* type, by whatever names they are known and of whatever colour are the flowers.

The dwarf or *pumila* section may be treated differently. The plants of this type, being of a dense cushion-like habit of growth, produce roots from the stems most freely during moist weather in autumn. If rooted slips or tufts are taken off, severing all the flowers from them, and these rooted portions are planted an inch apart in boxes of light sandy soil and placed in a close frame, the plants are soon established and form a compact surface of healthy growth. These boxes, wintered like the seedlings on a shelf in a light house, afford in the spring further slips in great numbers, or thousands of cuttings. For geometrical designs, panels, and low edgings the variety *pumila grandiflora* is not yet surpassed for general usefulness, and it ought not to be hastily set aside in favour of newer varieties with high recommendations attached, no doubt in good faith, by the vendors of plants. The improved form *pumila magnifica* has larger flowers, but the plant is less dwarf; it makes a beautiful edging to a moderate-sized bed, and is fine for pots. It may be grown in addition to, but cannot be safely substituted for, the former.

Of the somewhat stronger yet compact-growing varieties for general purposes, lines and edgings, the following are among the most useful. As an edging for a large bed the true *speciosa* from cuttings is one of the best, and from seed it makes a fine second row plant for a long border. Much dwarfier, rich in colour, and floriferous is the popular variety Brighton; it is excellent for edgings, close, dense, and bright. Ebor is darker and very effective. Blue Gem is paler, indeed is the purest blue of all. Lustrous has a distinct white eye; and Mazarine Gem is of the same type, both having a pleasing appearance in lines or masses. The new variety Blue Beard I have only tested on a small scale; it is highly promising and will be increased. Of the pink varieties Omen is still by far the best I have grown for a close line; it is very distinct, and indispensable to every well-furnished flower garden. The variety with what a correspondent has well described as the "funny name" of "What's That" is perhaps a trifle better in colour, but more straggling in habit, and will not drive Omen out of the garden. Of the silvery lilac forms Paxtoni, though still good, and coming fairly true from seed, making sparkling edgings, is superseded by Lady Macdonald and Dixon's Gem, which are charming when well grown in pots. One of the most useful whites is Princess of Wales, which is good in habit, pure, and free. When in good condition the double Lobelias are effective in pots and window boxes, but as edging plants they do not last sufficiently long in flower. Of the new yellow variety Lutea I can only say it is novel. Yellow it undoubtedly is, but the habit is loose and the flowers few; it will never make a good edging plant, and its proper place is, I think, a sunny rockery. It is so dissimilar from the ordinary type of bedding Lobelias as to make one wonder that it is included in the genus, and I shall be glad to see the result of the first cross that has been effected between this and one of the blue varieties above noticed. If my head does not ache before that is accomplished I fancy I shall not be troubled with that complaint for a year or two. I may, however, be wrong; we shall see.

Those who wish for a stock of any varieties of Lobelias that they do not possess should purchase plants now. They are generally kept in pots by those who grow them largely for sale, and such of these plants kept through the winter, potted and grown on in heat in early spring, may be increased a hundred-fold by the 1st of May.—A FLOWER GARDEN FOREMAN.

THE EFFECTS OF ELECTRICITY ON VEGETATION.

UPON page 265 Mr. Bridgman gives an extraordinary account of electrical influence upon plants, and were it not for the circumstantiality of the details I should have entertained grave doubts as to its accuracy. But the particulars of the experiments are so clearly stated that there can be no question as to the facts, though the causes are by no means so evident as are supposed. The first statement concerning the Fern case is the most remarkable. All the effects described may have been produced, but that they were the results of electrical action is open to doubt. The whole theory of galvanic electricity rests upon the necessity of two metals being in actual contact or connected by means of wire, the metals employed being of dissimilar constitution—that is, one must readily combine with the oxygen of acids, and the other resist that action. The more marked are these differences the better the battery, and the greater the intensity and quantity of the electricity produced. The metal which undergoes decomposition is termed the positive pole, and the unaffected metal is known

as the negative pole of the battery. Of the positive metals zinc is chiefly, and iron occasionally, employed; and of the negatives, copper, carbon, platinum, gold, and silver are the most important, the three first being most commonly used. In a galvanic battery thus composed the comparative quantity of electricity produced, provided the metals be the same in each case, will be in proportion to the size of the plates, but the intensity is in proportion to the number of pairs employed. A battery of a single pair of plates has but little chemical influence, and to effectually decompose chemical compounds it is necessary to increase the intensity of the electricity. The bearing of these facts upon Mr. Bridgman's statement concerning the Fern case are as follows: The metals of which it was composed—viz., zinc and iron, were similar in galvanic constitution, and therefore would under any circumstances produce a very small quantity of electricity, which would in that particular instance be still more reduced by the smallness of the surfaces in contact, for the edges could not exceed an inch or two in diameter. The amount of electricity evolved, presuming there to be any action at all, would therefore be so very small that it is highly improbable it could affect growing plants either injuriously or otherwise. I should be inclined to attribute the damping of the Ferns either to insufficient ventilation or to some obnoxious material having been employed in painting the inside of the case. As to the effect of placing strips of wood between the upper and lower portions of the case, let me ask, Were they placed all round so as to render the case as close as it was previously, or only at the ends or sides? If the latter, then the increased amount of air admitted would effectually dissipate the mildew. Finally, what soil was employed? This may have had some influence in the matter.

Mr. Bridgman's observations concerning manures are also, to say the least, unique. Manures are, he remarks, divisible into two classes—those containing oxygen and those devoid of that element; the former conveying "oxygenated food" to the plant through its roots, and the latter "producing mildew and other fungi." From this it appears that Mr. Bridgman regards oxygen as the chief food of plants, and those compounds that do not contain it as positively injurious. This requires some proof; for why is ammonia, consisting of nitrogen and hydrogen only, so beneficial to plants? Is it not because both the elements are of considerable importance to their health and are readily assimilated? Nitrogen especially is necessary to the sustenance of the living portion of the plant—the protoplasm, and the chief sources are nitric acid and ammonia; the former contains a portion of oxygen, and the latter none. Further, if these non-oxygenated compounds are so injurious to vegetation as your correspondent would have us believe, why are they beneficial to fungi, which are to a large extent of similar chemical composition to other plants?

Concerning the injurious effects of excessive applications of manure there can be no doubt, but the effect even then is to a great extent mechanical. The soil is so saturated that drainage is impeded, the plants cannot assimilate the nutriment fast enough, and consequently it decomposes, forming an abundance of acids that speedily exert an injurious effect upon the roots, and are doubtlessly absorbed into the tissues of the plants in such quantities as to produce disease and ultimately death.—NEMO.

BORDER FLOWERS—LINARIAS.

A SELECTION of the herbaceous Linarias cannot fail to interest the cultivator and admirer of choice border flowers, but some of the Linarias can only be seen to the best advantage in their native homes. One of the most beautiful is our common Toadflax, *Linaria vulgaris*, which when seen in the limestone districts on railway embankments, stone quarries, old walls, and other places is exceptionally beautiful. It also thrives under cultivation on the margins of the shrubbery or on the rockery. In the border it often becomes troublesome to the cultivator from its rapid increase. Its offspring, *Linaria peloria*, when once established if not checked will soon overrun a large space of ground, especially in light soil. I find them useful for cutting where yellow flowers are in demand. It is not my intention to enumerate all the species, but to call attention to a few. If anyone wishes to have a peculiarity let them procure the Three-bird Toadflax, *Linaria triornithophora*, (what a name!) and cultivate it in a compost of sandy peat and loam with well-decayed vegetable substance, in a moderately dry situation on a rockery exposed to the sun. The Ivy-leaved Toadflax, *Linaria Cymbalaria*, its white variety and the variegated form, are useful for covering old walls and moist places. The purple Toadflax, *Linaria purpurea*, is a distinct and showy plant, but seldom seen. The gaping Toadflax, *Linaria hians*, needs careful search, and will well repay any labour bestowed upon it. *Linaria tristis*, *L. marginata*, *L. venosa*, and others that might be named,

seem to be quite forgotten. Any moderately dry situation is suitable, and as a rule Linarias prefer sandy soil containing a good portion of decaying vegetable matter. They are readily increased by seed sown in the open ground in sandy soil in the spring, and by division of the plants in the autumn and the spring.—LINARIA.

TRINITY COLLEGE BOTANIC GARDENS, DUBLIN.

WHETHER the visitor loves trees, shrubs, plants, and flowers on account of their appearance, intrinsic merits, medical properties, or beauty, these fine, old, and admirably laid-out gardens will have a special attraction for him. Here the professors from the University, College Green, distant about two miles, find materials for illustration of their lectures, and occasionally take their pupils for practical instruction. Medicinal plants are separately arranged and classified. On the occasion of my visit the respected Curator, Mr. F. W. Burbidge, was absent in London; but the foreman, Mr. Kavanagh, took much trouble to point out the many rare and beautiful plants in the several glass structures, and the hardy collections out of doors, of which the few following notes, from memory principally, may have an interest for some of your readers. Although situated in the suburbs, owing to the tasteful arrangement of shrubs, &c., there is a complete isolation from city sounds and sights; and as the public are not admitted except on business, the horticultural student, amateur or gardener, may pursue his studies undisturbed. The borders are planted so as to be objects for imitation and general interest to the observer, and such as they can have at home, as distinguished from plants arranged according to their natural orders. There were fine specimens of Dahlias, Asters, Carnations, and of *Dianthus Eastern Queen* and *Crimson Belle*, the best I have ever seen, and apparently distinct from those generally grown. Convenient in an outside border was the Cardinal Flower, *Lobelia cardinalis*, which I was assured lives here without the slightest protection, though almost extinct in outdoor country gardens owing to the severity of the last few winters' frost. The same is true of the shrubby *Veronicas* and many others now flowering, such as *Schizostylis coccinea*. In fact many plants seem to reach dimensions not usually attained elsewhere, probably owing to the salubrious situation and the protection of high walls, except on the south.

The south-east winding border is well arranged for effect, with a background of such tall plants as Hollyhocks, Sunflowers (many of them were double) a stand of similar blooms at the last Dublin Flower Show were much admired, tall Phloxes, with the dwarf varieties near the margin, brightened here and there by the Flame Flower (*Tritoma Uvaria*), and with such dwarf plants as *Acæna microphylla* near the edge. The glass structures contain many rare and good plants. Very few Orchids, though the collection is considerable, are now blooming, though all seemed healthy, perfectly free from insects, and well grown. A handsome specimen of *Oncidium flexuosum* deserves notice, owing to the number of blooms it contained. The Lattice Plant (*Ouvirandra fenestralis*) seems here to do remarkably well grown under water which is very pure. It is planted in an ordinary 2½-inch pot in peat, and this is plunged in a vessel of water. There are many aquatic plants and mosses that look very interesting, as *Azolla pinnata* and *Salvinia natans* grown in pans of water, and with which some soil has been commingled. The latter fruits under the surface of the water, and the berries produce new plants the following year, thus providing for its perpetuation. Filmy Ferns seem unusually healthy, the system of growth pursued being to lay small pieces of spar on the young rhizomes in the pans to keep them growing down in a mass. The fronds were very fine. It may interest many readers to refer to the system here pursued of *Croton* and *Dracæna* propagation—viz., by slitting the stems, sawing the side out of a suitable pot, introducing the incised portion, and tying tightly around with sphagnum, &c. Rooting in a warm temperature rapidly occurs. I noticed the same system pursued with slight variation at Roebuck Castle and Powerscourt. I cannot conclude without referring to the fine fruit produced on a specimen *Musa Cavendishii*, and the small pots in which Mr. Burbidge succeeds in growing his Pitcher-plants. For instance, a specimen of *Sarracenia purpurea* was 18 inches high in a 2½-inch pot, proving that moisture was the principal requisite.—W. J. M., *Clonmel*.

THE GROWTH OF WELLINGTONIA.—I measured one of these trees a few days since which was planted on the day of the marriage of the Prince of Wales, March 10th, 1863. Its circumference 6 inches above the ground is 9 feet 7 inches. This seems to me to be very remarkable. An Oak would be growing 150 years before it attained such dimensions. It has often occurred to me that owners of large estates would do well to cultivate this

giant, as I apprehend the wood would be useful for building purposes. The tree is also very ornamental. An evergreen avenue or approach to a mansion, for instance, would be easy and of quick accomplishment. The tree referred to is in the parish of Hinton, Berks.—THOMAS MOSS.

CHRYSANTHEMUM ETOILE D'OR v. C. SEGETUM.

THERE was considerable praise bestowed upon Chrysanthemum Etoile d'Or when it first appeared, but when I first saw it I was greatly disappointed. Why our florists went to the expense of having it from France is beyond my comprehension; for in, probably, the first cornfield they meet with they could obtain a superior flower, and that is Chrysanthemum segetum. I am very glad to hear that Mr. F. W. Burbidge is at the present time engaged in saving seed from varieties of promise. Some of your readers will no doubt say that I have not seen the true variety, but as the plants came from Swanley they must be true.—W. ROBERTS, Penzance.

OUR attention has been directed to a rather peculiar instance of PRESS PIRACY, and singularly enough it has been suggested that we are the pirates instead of the victims, of what we must term a sharp and shabby example of Irish padding. A letter before us contains the following:—"In the last number of *The Garden* there is an article on 'Annuals for Spring,' taken ostensibly from an Irish paper. Is there such a periodical? and if so did you pirate the article in question? If you did not it has been stolen from you, as though slightly reduced, it is a reprint from page 242 of the *Journal of Horticulture*. I suspect the latter is the case, and I detest such dirty work." Though there is so much literary piracy now-a-days, more or less flagrant or more or less veiled, so much vamping up to fill dear pages cheaply, we are usually content to let them pass. In this case, however, we must put ourselves right with our correspondent and the public. We had observed the article referred to in the London paper previous to receiving the above letter, and endeavoured to purchase a copy of the "Irish paper." The London agents of that print could not supply it on the ground that it has no circulation in England. A friend, however, to whom it is sent gratuitously exhumed it from his waste paper store, and it is now before us. We are not surprised that it has no circulation in England, and we suspect that not many intelligent people of Ireland "take in" such a poor attempt at journalism, or are "taken in" by it. Truth compels us to state that poverty is stamped on the very face of the number before us, for every line of the two facing pages, 582 and 583—the best part of the number—is either borrowed or stolen, the article from our pages being in the latter category. Poverty and honesty often happily go hand in hand, and we regret to have to notice an instance to the contrary in the case in question. The curious example of literary patchwork referred to is too obscure to be named, but when it is made the medium for purveying stolen property to another paper of greater pretensions, it is time for us to interfere and to put the gardening public on their guard against such unworthy tricks. It is a wonder to us that such trash can exist in Ireland, where agriculture and horticulture are so admirably and honourably represented by our excellent contemporary the *Irish Farmers' Gazette*.

— NEXT year being the fiftieth anniversary of the opening of the gardens of the MANCHESTER ROYAL BOTANICAL AND HORTICULTURAL SOCIETY, it is intended to commemorate the event of holding a grand international autumnal exhibition of fruit, flowers, vegetables, implements, &c., and a general committee is in course of formation for carrying out the project.

— IN our notice of the MAIDSTONE FRUIT AND CHRYSANTHEMUM SOCIETY's schedule last week we inadvertently omitted to state that the Show will be held on November 19th. Mr. F. Pine, jun., Maidstone, is the Honorary Secretary.

— THE attention that is given to the cultivation of the DAHLIAS in the north of England is evidenced by the report of the Newcastle Autumn Show, which appears in another column. They are invariably an important feature at that Exhibition, but on this occasion nearly a thousand blooms were staged in competition, sufficient to produce a display of extraordinary brilliancy, and such as we have not had this year at any southern exhibition, if we except those "not for competition" displays at "the Palaces" north and south of the metropolis.

— THE VIOLENT STORMS that have recently prevailed have in many parts of the country proved very injurious to plants, shrubs, trees, and crops generally. This was especially the case in the neighbourhood of Wolverhampton, where on Sunday last a severe thunderstorm, accompanied by hail of great size, not only seriously affected plants outdoors, but also did considerable damage to the glass houses and their occupants. In other districts the heavy falls of rain have flooded roads, gardens, and fields, greatly injuring crops of all kinds.

— A VERY handsome plant for flowering at this time of the year is CEANOTHUS LATIFOLIUS, which is one of the finest of the genus. The bright blue flowers are borne in a dense thyrse-like inflorescence, and the main peduncles being long renders them useful for cutting, though the flowers are not of very long duration. Perhaps the best position that can be assigned to this plant is a border of good soil near the south-west or west aspect of a wall, to which the stems can be loosely trained. But almost any moderately sheltered position will suit it.

— WE regret to announce the DEATH OF MR. JOHN MANNINGTON of Uckfield, though, at the great age of ninety-three years, it was not to be expected that his life would be much prolonged. Mr. Mannington was an ardent raiser of seedling fruits, and up to the time of his death was engaged in his favourite pursuit. Mannington's Pearmain Apple, though raised by his grandfather, was first observed by Mr. Mannington, and when the original tree was on the point of extinction it was he who preserved it by securing grafts from it. Mr. Mannington has raised several excellent Pears of hardy constitution, which are now in the hands of Messrs. Paul & Son of Waltham Cross. So recently as last November we received specimens of his seedlings, and at the conclusion of a very long letter he finishes by saying, "I am ninety-two if I live till the 9th of February, and this is written without glasses."

— AS an ornamental tree for small avenues, pleasure grounds, and lawns in villa gardens, ROBINIA PSEUD-ACACIA BESSONIANA is one of the best, and is worthy of being more extensively planted. The ornamental character of this tree is admirably displayed at Chiswick, where Mr. Barron has planted it at intervals of about 15 feet on each side of the new road at the west end of the Royal Horticultural Society's Gardens. It is difficult to imagine that any other tree could produce the same satisfactory effect there. It combines elegance with symmetry in a very striking manner, and the fresh refreshing green of its graceful foliage contrasts favourably with the rusted and fading appearance of all other deciduous trees in the neighbourhood, an Occidental Plane perhaps excepted. Robinia Bessoniana forms a perfectly globular head, after the style of the Mop-headed Acacia, R. inermis, but is much freer in growth, larger and more feathery. This beautiful tree appears perfectly hardy, as it did not sustain the slightest injury by the severe frosts of last winter, and it is not too much to say that healthy handsome specimens such as those referred to would add

to the beauty of every lawn of suitable extent and every pleasure ground in the country. Intending planters should make a note of *Robinia Bessoniana*.

— MR. IGGULDEN has more than once adverted to the usefulness of the EGYPTIAN TURNIP-ROOTED BEET. Amongst other Beets this variety is largely represented at Chiswick this year, and Mr. Barron speaks highly in its favour on account of its earliness, excellence, and productiveness. We have long grown this distinct and good variety, and find that it is unsurpassed, if equalled, in quality by another of the long-rooted forms. It has less of the earthy taste that is more or less present in most Beet, and the absence of which is possibly attributable to the portion that is cooked being produced nearly or quite above ground. The Turnip-rooted Beet is not by any means grown so largely as its merits demand, and those who have not yet included it in their gardens may safely give it a trial.

— A CORRESPONDENT describes *CHLORA GRANDIFLORA* as a splendid plant for pots to flower in spring and early summer. Its golden yellow flowers, starry with many petals, produce an effect of colour and elegance not easily forgotten. Seeds should be sown at once, and its culture should be that of annuals to flower in spring.

— THE uprooting of the EDELWEISS plant has been strictly forbidden in Switzerland. The cantons of Berne and Obwalden have issued a police ordinance forbidding the plant being passed if it has roots.

— WE have received the schedule of the first autumn Show of the LIVERPOOL HORTICULTURAL ASSOCIATION, the date of which is fixed for November 23rd. It contains six classes for Chrysanthemums in pots and seven for cut blooms, the prizes ranging from 60s. to 10s. There are fifteen classes for miscellaneous plants, the principal prizes being £5, £3 10s., and £2 for ten stove and greenhouse plants, not less than four to be in bloom, and there are nineteen classes for fruit, the prizes for a collection of twelve dishes being £3, £2, £1. Considering the skill with which Chrysanthemums are grown in the Liverpool district, and the broad and liberal condition that "specimens may be exhibited from any part of the world, and by any person, either for sale or for competition, or may be marked not for competition," a Show worth seeing may be confidently expected. The Show is under distinguished patronage, and has an essentially practical Committee, of which Mr. Washington, 37, Aigburth Road, Aigburth, is the Secretary.

— MR. YOUNG, gardener to Henry Webb, Esq., Redstone, Redhill, Surrey, informs us that he obtained a bushel of CARTERS' MAGNUM BONUM POTATOES, which he cut into single eyes and planted 30 inches by 18 in sandy soil in April, and he has just dug 34 bushels of good sound tubers—the most satisfactory yield of Potatoes he has seen on Mr. Webb's estate for twenty-eight years.

— MR. GUIDO SCHMITT writes as follows to the *Daily News* on ARTIFICIAL FLOWERS:—"This article has of late been manufactured and used on a constantly growing scale, in spite of the improving good taste which shows itself in so many ways. Artificial flowers anywhere except on the stage are unæsthetic, and should not be considered legitimate ornaments. Ladies and children wear them on bonnet or dress, where none but real flowers ought to be seen. 'They do not last' is the excuse; but in their fading and dying lies the tragic poetry of Nature—the fate for the living fresh flower. Gentlemen only wear real flowers in their button-hole. If they suddenly began to wear artificial ones the barbarous ridiculous fashion would strike us at once. Habit makes us think that the imitation flower is fit for ladies and not for gentlemen, but the hint thereby conveyed is indisputably

important. No one who has reverence for Nature can, upon reflection, admire or wear these sham things. The manufacturer of flowers, however wonderful his performance, effects what he pretends to be a substitute for Nature; he merely makes an idol full of disappointment."

— THE AMERICAN PEACH SEASON is now drawing to an end. So far there have arrived in Boston upwards of three hundred and sixty cars of Peaches, or nearly two hundred thousand baskets, an increase of about 100 per cent. over last season's receipts. The Peach season is a very hard one on the receivers. They begin at three o'clock in the morning to gather at the freight-yard, are busy throughout the day selling and delivering the fruit, and at the close are kept employed until eight and ten in the evening sorting and loading the baskets to be returned, and making up account of sales. Three or four dealers each handle from three thousand to four thousand baskets daily, which come from about 1300 shippers. It is estimated that through the season, which lasts from five to six weeks, there are about 2200 different Peach-shippers sending to Boston. Each shipper is advised daily of the condition of the market, and the accounts are made up and remittances forwarded twice a week. Stating the average of the present season's sales by receivers to have been at 1 dol. 20 cents a basket, about 250,000 dols. has been sent from Boston to Delaware farmers. The crop is supposed to be about a three-quarters one, that is about nine million baskets. The crop of 1875, said to have been twelve million baskets, was the full season. That year, however, it is thought quite certain that the farmers all ran in debt with their Peach business. The highest price good Crawfords averaged that year was one dollar a basket, and at that they were reshipped from New York, which necessitated the paying of two commissions. This year 1 dol. 75 cents and 2 dols. have been the high averages on lots of choice Crawfords.—(*American Cultivator*.)

PEONIES.

A FAMILY of large-growing, showy-flowered plants, remarkable for the shrubby habit which one section (Tree Pæony) assumes, a character so very rare amongst members of this order. It is extremely difficult to understand why such glorious flowering plants as the Tree Pæonia and its varieties should at the present time be so very rarely seen in English gardens, whilst the herbaceous section, although not quite so large, are by no means deficient of merit. They are splendid objects in shrubbery borders, in the wild garden, or any place where gay and ornamental plants are desired. They are specially valuable for planting in spots overshadowed by tall trees. Here, where most plants drag out a miserable existence or die, the herbaceous Pæonies flourish, throwing up their bold compound leaves, and unfolding their large and conspicuous flowers, which last for many weeks in full beauty. The Moutan or Tree Pæony is not quite so hardy as the herbaceous, but the extraordinary size and beauty of the flowers should be sufficient reward for any amount of trouble. Planted on the lawn and slightly protected in winter, they repay this slight trouble a thousandfold by unfolding their enormous but brilliant flowers in spring. For wall plants they are also admirably adapted, and in such positions can be very easily protected. Whilst referring to the subject of protection, these, and indeed many other plants which require a little help to tide them over our peculiar seasons, more often reap injury than assistance from the methods adopted to protect them. I hold it quite as essential to shelter them from the effects of early spring sunshine as from frost. There is more probability of enjoying the flowers by retarding than by allowing them to be started into action early in the season, when we sometimes have strong sunshine succeeded by cold and piercing winds. Therefore we should advise the protecting material to be only used in cases of severe frost, and on bright sunny days through the winter and early spring. Of course when used against sunshine there must be a space left to allow a current of air to pass through between the plant and the material, in order to keep a cool temperature.

As a genus Pæonia may be thus characterised. Roots in the one section fusiform with herbaceous stems. In the Moutan section the stems are more or less woody and branching, attaining a height of 3 to 5 feet or more; they have five unequal, imbricate, leafy

sepals, and five to ten broad, roundish, conspicuous petals. Carpels two to five, many-seeded. Disk fleshy. These plants will thrive fairly in any good garden soil, but prefer light and rich sandy loam. After planting they will give little trouble, as they dislike the ground disturbed about them, which is another proof that the periodical digging in herbaceous borders is a very great mistake. The following is a selection well worthy the attention of all owners of a garden. It, however, by no means exhausts the supply. *Pæonia Moutan Anneslei*, alba grandiflora and fl. pl., atro-purpurea, Beauty of Canton, Candidissima, Dr. Bowring, Emperor of China, Glory of Shanghai, Ocellata, Papaveracea alba plena and rubro-plena, Robert Fortune, Rollissoni, Rosa Mundi, Roseformis, Samarang, Triomphe de Gand and Malines, Victoria and alba, *Viola* purpurea and fl. pleno, Zenobia.

In the herbaceous section there are many fine varieties. Those here named will not fail to please every lover of hardy and showy flowers. *Alba superba*, *Anemoniflora carneo-tincta*, *Atrosanguinea*, Auguste Van Geert, Candidissima, Carnea maxima, Centifolia rosea, Charles Binder, Edmond Lebon, Eugène Verdier, Festiva maxima, Gloire de Douai, Henry Demay, La Sublime, Leonie, Madame Chaumoy, Madame Victor Verdier, Madonna, Marie Dhour, Prince Charles, Prince Imperial, Prince Prosper, Tenuifolia, The Queen.—H. G.

THE PARKS OF LONDON.—No. 3.

VICTORIA PARK.

THE brilliant display of bedding-out that usually characterises this Park during the summer season has this year fully maintained its reputation. Tastefully designed carpet beds, fine masses of *Pelargoniums*, *Coleuses*, and similar plants, have produced a magnificent show of colour, while borders of miscellaneous hardy plants have contributed to the general brightness; and even now, when the beauty of the beds in other portions of the Park is waning, the "mixed border" still forms one of the chief features. Subtropical gardening is also represented, so that there are examples of each style of bedding, and all are well executed.

That assemblage of beds, commonly known as "the Prince of Wales' Feather beds," constitutes the most attractive portion of the display to the majority of visitors. There the dazzling colours derived from scarlet, salmon, or pink *Pelargoniums* have been judiciously combined and contrasted with the deep shades of *Iresine Lindenii* and *Colcus Verschaffeltii*, the pure white of *Centaureas* and the soft lavender blue of *Ageratums* resulting in a most satisfactory effect. The *Pelargoniums* have been exceptionally fine, but they are now past their best, though the *Coleuses* and other plants employed continue attractive. What are chiefly remarkable are the neatness of the general appearance—the plants when they require it being kept well pinched in so as to form regular lines or compact clumps—and the peculiar richness of the colours in the foliage and flowers. The *Iresines* and *Coleuses* are especially noticeable in this respect, and several large beds of the latter are models of exactness, the surface being as even as if it had been mown. The *Centaureas*, too, are as white as possible, and the *Ageratums* have flowered very freely. In addition to the numerous beds containing the plants above indicated, there is a few on each side of the central design and near the path, which are tastefully planted as carpet beds; these are of circular and oblong form, the ground being composed of *Mentha Pulegium gibraltarica*, upon which are raised star-shaped and other panels with a similar ground neatly edged with small plants of *Echeveria secunda glauca*, lined with *Alternanthera paronychioides major*, and containing small clumps of *A. amœna*. The simplicity of the designs, the few varieties of plants employed, and the brightness of the *Alternantheras*, render these beds very neat and pleasing.

Proceeding farther to the east we come to several carpet beds of great beauty, occupying a sheltered position near that portion of the Park devoted to subtropical plants. The one that first attracts attention is extremely long and narrow, of serpentine form. This is edged with *Echeverias*, and has a ground of *Mentha*, from which rise numerous small panels of *Alternantheras*; single specimens of *Sempervivum tubulaforme* and *Echeveria metallica* with other similar plants are dotted at intervals in the centre. Right and left of this bed are beds of moderate size that might be described as hexagons, of which the sides have been converted into semi-circles, with the convex side turned outward. These are some of the best and most effective of any we have seen this year. They are margined with *Echeverias*, next to which is an edge of *Alternanthera amœna*, and then a similar line of *Mesembryanthemum cordifolium variegatum*, both these extending quite round the bed. The ground is composed of *Herniaria glabra*, as close and dwarf as if it had been rolled, and of a most intensely dark green tint; upon this is raised in the centre a star-shaped panel margined

similarly to the outer edge of the beds, and containing lines of the Golden *Pyrethrum* and dense clumps of *Alternanthera versicolor grandis*. The other portion of the beds is also relieved by small panels of similar design. The peculiar distinctness of these beds is remarkable; the lines of *Echeverias* contrasting so strikingly with the *Herniaria* brings out the design in bold relief.

Of the subtropical department little need be said. *Cannas*, *Ricinuscs*, *Ficuses*, Tobacco Plants, and *Wigandias* are well represented, some beds of the latter being exceptionally fine. All are in most vigorous health and very satisfactory. One feature, however, deserves notice—viz., a large bed of single Dahlias, which for brightness could scarcely be surpassed. It proves with what advantage these now comparatively neglected varieties can be employed in gardens. The borders of hardy plants have been already referred to, and it only remains to note that their principal attractions now are the Dahlias. These are freely employed; a good selection of colours has been made, and the white varieties are sufficiently numerous to relieve the brighter tints. In one rather dark position—namely, that occupied by the carpet beds last described—the border in front of the shrubs is almost exclusively devoted to white Dahlias, which serve to lighten the slightly sombre effect considerably, and do not detract from the brilliancy of the other beds, as many colours would have done. As regards the general condition of the Park, it is as satisfactory as it has always been under Mr. McIntyre's superintendence.

HYDE PARK.

The aristocratic Park of the metropolis as usual contributes its share to the pleasure and instruction of that portion of the public which is specially interested in that form of decorative gardening known as bedding-out. The chief display of colour, indeed nearly all the beds devoted either to carpet designs or the ordinary style, extend in one long series between the Park Lane boundary and the carriage drive. There, owing to the large number of *Pelargoniums* employed and the satisfactory manner in which they have flowered this season, the effect has been exceptionally brilliant. The majority of the beds are edged with *Lobelias Blue Stone* or *pumila magnifica*, Golden Feather, and the variegated *Pelargoniums Albion's Cliffs* or *Princess Alexandra*, the centres being occupied with scarlet, pink, and white Zonal *Pelargoniums*. It is well known that the formality of such bedding and the repetition of bright colours employed constitute its chief defects, and consequently it is pleasant to observe some attempt to vary the prevailing monotony. This is shown in the introduction of a number of what are termed "mixed beds"—namely, such as have the centre composed of two or more distinct kinds of plants in alternate lines, which either by the harmony or contrast of their colours are suited for association. One combination, of which examples are frequently seen, is that of planting a golden-foliaged variety of *Pelargonium* with one of the bedding *Violas* in a circular bed near the Marble Arch end of the Park. The former is represented by *Verona* and the latter by *Viola Blue Bell*, which contrast very well, especially as they are relieved by the margin of *Pelargonium Albion's Cliffs* and *Lobelia Blue Stone*. Another bed in the same style has, however, a very different effect, and is almost more peculiar than beautiful. This is composed of *Crystal Palace Gem Pelargonium* and *Amaranthus melancholicus ruber*. A third example contains the variegated *Pelargonium Miss Kingsbury* with *Perilla nankinensis*, which also has a curious effect, but rather more pleasing than the one previously mentioned. As a slight variation of the first a long bed is planted with *Pelargonium Aristo* and the same *Viola*, but this does not seem to have proved very satisfactory, for the *Viola* has almost hidden its companion. Perhaps the most satisfactory of all is a bed comprising an unnamed variegated *Pelargonium*, probably *Princess Alexandra*, and *Iresine Lindenii*. Both have thriven well, and the colour of the *Iresine* is particularly rich. A neat but not very showy effect is produced by the combination of *Pelargonium Princess Alexandra* with *Ageratum Tom Thumb*. These "mixed beds" are the chief features deserving of notice, the majority of the others being in the ordinary style. It is perhaps worthy of note that, in addition to the edging already referred to, many beds are margined with *Lobelia Omen* and *Pelargonium Robert Fish*; both have done very well; but the *Lobelia* has been uncommonly fine, the purplish mauve coloured flowers having been most freely produced. A clump of *Abutilons* (*A. Thompsonii*), *Lantanas*, and *Amaranthuses* is fairly satisfactory, but it is questionable if the two latter might not have been omitted with advantage, for they scarcely improve the appearance of the *Abutilons*, which have their foliage brightly coloured. The carpet designs are not very numerous, but fairly characteristic. The one which most attracted our attention was neat and effective, being devoid of that intricacy which too frequently marks such beds. It was only 4 or 5 feet in diameter, four-lobed in shaped, edged with *Echeveria secunda*

glaucous and *Mesembryanthemum cordifolium variegatum*. The ground is of *Mentha Pulegium gibraltaria*, in which are dotted single plants of *Paehyphyton bracteosum*; in the centre is a square of *Alternanthera amoena* margined with *Kleinia repens*—a very pretty and informal design.

In other portions of the Park, particularly in "The Dell" and near Rotten Row, are imposing clumps of *Cannas* and *Ricinus*, with a few single specimens of Palms and *Musas* judiciously

situated to impart a subtropical appearance to these positions. The Park has been greatly admired throughout the summer.

RUDBECKIA NEUMANNI.

Few amongst hardy herbaceous plants are more bright and effective during the late summer months than this fine *Rudbeckia*. The flowers are of a bright deep yellow, and are rendered

Fig. 57.—*RUDBECKIA NEUMANNI*.

the more ornamental by the prominent dark central florets. The plants grow with great freedom, and flower most profusely during a period of six weeks. It varies in height according to the nature of the soil in which it is grown, and the dryness or wetness of the season. I have admired it in masses about 18 inches in height and more in diameter, and have seen it even more imposing when more than twice that height. For the back of herbaceous beds,

and for the front, between the shrubs, of shrubby borders, this plant is equally telling, and should be grown in all gardens where such plants are cherished.—J. D.

THE COMMON HEMP.—This is a valuable plant for its foliage in summer. We have seen little of late years, but in the Cambridge

Botanic Garden along a border are plants 8 and 10 feet high, which have a graceful effect from the mass of feathery branches. It is astonishing how few there are who know what it is.—L.

PLANTING ROSE TREES.

Now that the season for this work is just upon us it would be well if a matter about which there seems to be some doubt could be cleared up. It is generally admitted that standard Roses do best when planted about 5 or 6 inches deep, and that Manetti Roses should be so planted that the junction of bud and stock shall be about 2 inches below the surface of the ground; but when we come to deal with dwarf Roses on the Briar there is a diversity of opinion as to what depth they should be planted. Canon Holc, their great champion, speaks of the junction of the bud with the stock being below the surface, so as to give the Rose a chance, as when on Manetti, of throwing out roots of its own. Mr. Prince of Oxford, a great trade grower of seedling Briar Roses, does not refer to the point of budding at all, but simply says that his Roses should not be planted too deeply, but at the same depth as previously; while some other nurserymen, after speaking of Manettis being planted so as to cover the budding, say that such planting in the case of dwarfs on the Briar would be almost if not quite fatal.

As Roses on this stock are undoubtedly becoming more and more popular it is important that something positive should be known upon the point of planting. If it be true that it is necessary to keep the budding above the surface of the earth it will be best to grow Manettis; as with them, if the Rose should be killed down to the ground, it will spring up again from the protected buds below ground, while nothing but the stocks of Briar Roses will be left alive. Perhaps some of your readers have tried dwarfs on Briar planted both ways, and will give us their experience. Is there any difference in the cases of seedling Briar Roses and those on Briar cuttings? I have a number of Briar cuttings budded lately which I should like to move this autumn. Will it be safe to do so?—J. B.

THE INTERNATIONAL POTATO EXHIBITION, CRYSTAL PALACE.—SEPTEMBER 22ND AND 23RD.

THIS was the finest Exhibition of Potatoes that has ever been held in England, both as regards the number of the competitors and the quality of the tubers. There were upwards of a hundred exhibitors, who staged nearly four hundred collections, including about 2500 dishes, and representing more than 22,000 tubers—a magnificent display. The competition was generally keen, and the majority of the tubers were characterised by a remarkably even and clean appearance. The arrangements were all satisfactorily conducted by Mr. J. McKenzie, the Secretary.

In the open class A, for twenty-four distinct varieties, six prizes were offered of the total value of twenty-eight guineas, the first, second, and third being respectively ten, seven, and five guineas each. The President of the Society, the Lord Mayor of London, contributed the first prize; Messrs. James Carter & Co., 237, High Holborn, the second and third; Mr. Charles Turner, Slough, the fourth; and G. R. Bengough, Esq., Brixton Road, the fifth; the remaining award being provided by the Society. This was the chief class of the Exhibition, the competition being close, and the exhibits of good quality generally. Seventeen collections were staged. The premier award was secured by Mr. Richard Dean, Ranelagh Road, Ealing, with an even and handsome collection of clean tubers. The varieties were Snowflake, Grampion, White Emperor, Beauty of Hebron, Cosmopolitan, Early Ohio, Climax, Mr. Bresee, Covent Garden Perfection, Vicar of Laleham, Emerton's Advance, Radstock Beauty, International Kidney, Heather Bell, Early Market, Triumph, Lord Mayor, Garibaldi, Magnum Bonum, American Purple, Bedfont Prolific, Manhattan, Schoolmaster, and Blanchard. The second prize was secured by Mr. W. Ellington, West Row Gardens, Mildenhall, with a fine collection, including the following varieties, in excellent condition:—Manhattan, The Mammoth, Pearl, Vicar of Laleham, Blanchard, Breadfruit, Trophy, Beauty of Hebron, and Porter's Excelsior. Mr. John Reid, Ayrshire, N.B., was third with neat examples; E. Twopenny, Esq., Sittingbourne (Mr. James Matthews), was fourth; J. R. Wigram, Esq., Salisbury (Mr. R. West), was fifth; and Messrs. Lott & Hart, Faversham, sixth.

Class B, for eighteen varieties, was open only to gentlemen's gar-

deners, and the exhibits were judged by three non-competing gardeners. Messrs. Sutton & Sons, Reading, offered the six prizes in this class, which amounted to twenty-two guineas, the first prize being seven guineas. Twenty-seven collections were exhibited. The best collection was from the Duke of Marlborough, Blenheim, Oxon (Mr. W. Crump), and included the following varieties in superb condition:—Snowflake, Grampion, Mona's Pride, Schoolmaster, Bedfont Prolific, Radstock Beauty, St. Patrick, Woodstock Kidney, Webb's Surprise, International Kidney, Vicar of Laleham, Beauty of Hebron, Blanchard, Rector of Woodstock, Triumph, Porter's Excelsior, Early Vermont, and King of Potatoes. The second prize was secured by Mr. J. Millen, Hampstead Park Gardens, Newbury, with even samples clean and healthy; the best were Snowflake, Radstock Beauty, Grampion, Mona's Pride, Blanchard, Defiance, The Washington, and Porter's Excelsior. Mr. John McIntyre, Woodridge Gardens, Darlington, was third with small but wonderfully even clean samples, Oneida and Vicar of Laleham being especially noteworthy. Mr. J. Matthews was fourth; Mr. James Harper, Monaltrie Gardens, Ballater, N.B., was fifth; and Mr. W. Sedge sixth.

All the remaining classes were open to any exhibitors. Class C was for twelve varieties, and five prizes were offered, the first by Mr. Alderman Hadley; the second by James Albiss, Esq.; the third by L. Fawell, Esq., 4, St. Paul's Churchyard; the fourth by Messrs. Kerr & Fotheringham, Dumfries; and the fifth by the Society. Twenty-six collections were staged. First honours were awarded to Mr. William Kerr, Dumfries, N.B., for a satisfactory collection including Schoolmaster; Triumph, excellent; Beauty of Hebron; Trophy, very fine; Magnum Bonum, Salmon Kidney, Mammoth, Pearl, Grampion; Porter's Excelsior, even and neat; Manhattan, Pride of America, and Oneida. The second prize was secured by the Rev. J. Bramah, Faversham (Mr. G. Akhurst); the best of his varieties were Beauty of Hebron, Early King, Beauty of Kent, Climax, and Trophy, all of good size and shape. Mr. T. Pickworth, Loughborough, was placed third, Mr. W. Crump fourth, and Mr. J. Millen fifth. Other good exhibitors were Col. Cartwright, Byfield (Mr. J. Hughes); Mr. W. Finlay, Wroxton Abbey Gardens, Banbury; and J. R. Wigram, Esq., Salisbury (Mr. R. West).

In class D, for six varieties, the first three prizes were given by Messrs. H. & F. Sharpe, Wisbech, Cambridgeshire; Messrs. Barr and Sugden, Covent Garden; and William Holloway, Esq., 5, St. Paul's Churchyard respectively; the funds of the Society providing the two other prizes. Thirty-nine collections were exhibited. The chief position was secured by Mr. W. Kerr with fine dishes of Schoolmaster, Grampion, Pride of America, Vicar of Laleham, Porter's Excelsior, and Trophy. Mr. Akhurst was second with Magnum Bonum, Brownell's Superior, Beauty of Kent, Schoolmaster, Early Rose, and International Kidney, all clean and good. Mr. R. Dean was third; Mr. W. Finlay was fourth; and Mr. H. Minchin, The Nurseries, Hook Norton, fifth.

In Class E, for four varieties, two coloured and two white, P. McKinlay, Esq., and James Crute, Esq., offered the first and second of the four prizes. There were twenty-eight entries. The winning collection was from J. Friend, Esq., Margate (Mr. F. Miller), with Jackson's Improved, Yorkshire Hero, Vicar of Laleham, and Blanchard, clean, fresh, even, and of good size. Mr. J. Millen was a good second; Mr. W. Kerr third; and Messrs. Lott & Hart fourth. Messrs. Hooper & Co., Covent Garden, contributed the four prizes in class F for four distinct new varieties in commerce that had not been offered to the public previous to 1879. There were twelve competitors. The most successful exhibitor was Mr. F. Miller with Vicar of Laleham, Beauty of Kent, Pride of America, and Woodstock Kidney, all in good condition. Mr. R. Dean was second with Avalanche in the place of Pride of America in the previous collection, the other varieties being the same. Mr. F. Matthews was third with Radstock Beauty in place of Vicar of Laleham in the first-prize collection. Mr. Peter McKinlay, Headly Lodge, Penge, was fourth with Matchless in the place of Woodstock Kidney. The Amies Chemical Manure Company, 79, Mark Lane, London, also offered four prizes in Class G for one round and one kidney variety. Twenty-eight collections were staged. Mr. W. Kerr was first with Schoolmaster and Pride of America, both excellent. Mr. J. Millen was second with Blanchard and Magnum Bonum. Mr. John Reid third with the latter variety and Climax; and Mr. R. Dean fourth with International Kidney and Blanchard.

The remaining classes were all for single dishes, the three prizes in each class being contributed by firms of seedsmen and nurserymen. In Class H, for any white round variety, the prizes were given by Messrs. Daniels Brothers, Norwich. Twenty-four collections were staged. Mr. W. Kerr was first with Schoolmaster, very even and clear; Mr. R. West second with the same variety; and Mr. J. B. Hall, Gillingham, Kent, third with Early Goodrich. In Class I, for any coloured round variety, Messrs. Harrison & Sons, Leicester, contributed the prizes. There were twenty-eight entries. Mr. R. Dean was first with Vicar of Laleham, very neat; Mr. F. Miller was second with Red Emperor; and Mr. R. Ironside, Ingleston, Inverness, N.B., was third with Grampion, very fine. For any white kidney variety Messrs. Thomas Gibbs & Co., Piccadilly, London, were the prizewinners. Twenty-six dishes were exhibited. Mr. James Counce, Garstang, Lancashire, were first with International, handsome; Mr. J. Miller, second with Myatt's Ashleaf; and Mr. R. Ironside third with International Kidney. For any coloured kidney variety Mr. Richard

Dean, Ealing, offered the prizes. Twenty-five dishes were staged. Mr. R. Dean was first with Mr. Bresee; Mr. James Caunce was second with Fenn's Bountiful; Mr. C. Osman, Sutton, Surrey, being third with the same variety. Messrs. Sutton & Son, Reading, gave the prizes in Class M for a dish of Suttons' Magnum Bonum; and in Class P, for a dish of Suttons' Woodstock Kidney, there were fifty-three competing collections, all of good quality. Mr. W. Kerr was first with samples of moderate size, very even and clean. The Hon. Mrs. Hay, Market Lavington, Wilts (Mr. James Lye), was a close second; and Mr. W. Ellington third. For the best dish of "Schoolmaster" in Class N, Messrs. Webb & Sons, Wordsley, Stourbridge, were the donors of the prizes. There were twenty dishes staged. Mr. William Kerr was first with handsome clean tubers; Messrs. Lott & Hart with good examples but not so clean; Mr. Henry Gibbs, Ightham Court Gardens, Sevenoaks, being a good third.

Messrs. John Laing & Co., Forest Hill, offered prizes for the best dish of any new variety. Eighteen dishes were exhibited. Mr. Peter McKinlay was first with Wiltshire Snowflake, a round white variety raised by Mr. Lye, Lavington Hall, Wiltshire. Mr. R. Dean was second with Lord Mayor, a seedling from Extra Early Vermont crossed with Early Market, a second early variety said to be of fine quality and free cropper. C. Eyre, Esq., Newbury (Mr. Ross), was third with Dux, a seedling round variety from Victoria. For the best dishes of Suttons' Woodstock Kidney Messrs. Sutton offered the prizes. There were thirteen entries. The first prize was secured by Mr. C. W. Howard, Canterbury, with fine examples, Mr. Henry Gibbs followed closely, and Messrs. Lott & Hart were third. All the tubers were of excellent quality, even, and of good size.

Miscellaneous exhibits were numerous. Messrs. Sutton & Sons, Reading, had a very large collection, occupying a space of 200 square feet, over one hundred varieties being represented. Messrs. James Carter & Co., High Holborn, exhibited heaps of Magnum Bonum and Scotch Champion Potatoes, including samples of the latter variety grown in twenty-four English counties. Messrs. Harrison & Son, Leicester, contributed a number of dishes. Mr. Charles Turner, Slough, had some good examples of Schoolmaster. Messrs. Webb & Son, Stourbridge, also sent a number of dishes, International Kidney being especially remarkable for its size; the fine variety Schoolmaster was well represented. Messrs. James Veitch & Sons, Chelsea, sent about forty dishes of fine Potatoes, and about eighty dishes of Apples. Messrs. Charles Lee & Son, Hammersmith, sent a number of good examples. Messrs. Daniels Brothers, Norwich, had a handsome collection of a hundred varieties of Potatoes in fair condition.

THE CULTURE OF MIGNONETTE.

MIGNONETTE is a general favourite on account of its delightful fragrance, but it is seldom seen in good condition except in market-growing establishments. It is of easy culture, and within the reach of everybody. The present is the best time to sow the seed for raising plants for spring blooming. The most useful-sized pots are 48's, and the most suitable compost two parts of turfy loam and one of decomposed cow manure, with a sprinkling of old lime rubbish. Place over the crocks about 2 inches of decayed manure (as the Mignonette delights in a rich compost), and fill the pots with the above compost; press the soil in firmly, sow the seed rather thinly, and sprinkle a little soil over it, plunge the pots in a cool frame in ashes within 3 inches of the glass, supply water rather sparingly till the seed germinates, after which the plants should have very little water. Thin the plants out well, retaining about six or seven in each pot. Ventilate freely night and day to keep the plants sturdy, leaving the lights off altogether on all favourable occasions. Discontinue watering from the middle of November till the end of February. This is the secret of success, as if the plants are watered through the winter they become weakly and drawn, and the result is never satisfactory. Do not mind the plants flagging a little, which sometimes they will do when the sun is rather strong. About the first week in March they will require to be watered rather more, never allowing them to become dry; ventilate freely, and when they show bloom water with liquid manure. Place a neat stick to each plant, so that the air may circulate well amongst them.—FLORIST.

THE POTATO DISEASE.

SOME thirty years since I was led to believe that the disease was caused by an excessive rainfall. Observation and experiments in growing the Potato deepened this belief, but how it was done puzzled me for years. My theories were overthrown by the stern logic of facts. Still I was growing nearer the truth; and now I think I have approached it so nearly, that at least it is worthy of a place in your Journal and the consideration of your able contributors. You will, I trust, permit it to be freely and fairly discussed.

I hold that the fungus is a result, not a cause. The cause is too much wet at a particular time. The disease of the Potato is

induced thus: During the growth an abundance of rain gorges the tissues with sap, and at the same time the densely saturated air prevents effective respiration to such an extent as to rupture the organs of the plant sufficiently to hinder it from accomplishing its work of properly forming and ripening its tubers. At present this is only an induction, but it enables me to explain all the developments of the disease that have come under my observation, and it is, I think, capable of practical demonstration.

It may be interesting and perhaps helpful if I state how I was led up to this theory, and why I think it capable of proof. The very close planting which used to be practised more than now, or overcrowding, was an early-formed theory of the disease, but it had to be given up, not, however, until it had taught me that it had very much to do with its cause. I found that good drainage, room for free circulation of air and access of the sun's rays, were essential to sound tubers. In short, Potatoes have been improved or abused until they claim sensible treatment. Still, sensible treatment, careful attention, and selection of varieties did not dispose of the disease, but it did the next best thing—it mitigated it very much, and it led me to conclude that if I could limit the rainfall I could conquer the disease. I grew them under glass, and remembering that it was an inhabitant of a dry climate I supplied water judiciously. The result was perfectly sound Potatoes. This has been done on a small scale for several years with the same result. This year I planted partially diseased Potatoes and watered with liquid from a well, and had no sign of the disease.

These facts have led me to infer and state that I believe the Potato can be grown to demonstrate the cause and all the consequences of the disease we have observed. I should prefer, however, to treat of that in a future issue.—AN INTERLOPER.

MR. LUCKHURST (page 258) states that the plague spot of the Potato disease appears first and the fungus invariably afterwards. I am by no means indisposed to agree with Mr. Luckhurst in some of his ideas on the subject on which he writes, but I would be glad to be informed if this statement is true, or admitted by those competent to investigate the matter. If the disease appears in the tuber before the fungus presents itself, that is quite sufficient to prove that the latter has nothing to do with the disease. Will Mr. Luckhurst kindly say where he derives his information from? and oblige—A READER.

I AM very glad our "author" has modified his former statement that half the Potato disease was caused by the ignorance and apathy of cultivators. Only a cultivator of comparatively limited experience could have entertained an idea so erroneous, and certainly a writer who can only support his views on this subject by extracts from newspapers will not be regarded as a practical teacher by practical men. I am asked to read our "author's" book more carefully. I have read it, and I find the depth of planting is qualified on one page but not on another. As an historical compilation the work is interesting, but the writer does not deny that only one-tenth of it is founded on his own practice, the nine-tenths being a record of the work of other people—a curious exemplification, surely, of the apathy and ignorance that has been applied to cultivators generally!

It is not a practical book at all. There is not a cultural suggestion in it that has not been tried, and certainly one "recommendation" has been found wanting—namely, "cutting" off the tops of the plants for averting the disease. Pulling them off has been of great benefit, yet this is not mentioned; cutting them off is simply labour in vain. Neither is the theoretical plan for the extinction of the disease of any practical value. Even if the Government were to take possession of the Isle of Wight and the Isle of Man and prohibit the culture of Potatoes there for a year by act of Parliament, as is recommended, no good would result; at least Mr. Worthington Smith says it would not, and I presume no one in the Queen's dominions can speak with more authority on the Potato fungus, its nature and movements, than he can. Let us see what he says in one of his latest contributions to the *Agricultural Gazette*, from which I extract the following:—

"As for stamping out the murrain, or isolating cultural experiments to an island in the sea a short distance from the shore, any such attempt would be utterly futile. Spores are present everywhere, and can no doubt be carried through the air across a sea or ocean as readily as over a hedge. Spores everywhere sail with the wind, and at the same speed. Nothing is better known than the descent of spores, pollen, and other minute organisms on to ships in mid-ocean. If Potatoes were taken into an island in the middle of the South Pacific, or transported upwards for miles into the air, or submerged for years in a river, they would yet be liable to contamination from the *Peronospora*, for the spores of the

fungus are everywhere. The resting spores have been kept alive for three years simply in pure water, and they germinated after this time. In fact, the only way to satisfactorily see the ordinary spores germinate is in water. I have for many years been in the habit of constantly using the microscope, and I have found the spores of the Potato fungus on the most diverse objects, and from the most diverse positions, showing that the spores must have been blown for long distances in every direction. Now, suppose the statement to be correct (although it is not correct) that the spores of the Potato fungus are not carried far by the wind, are there no other means of dissemination at hand than disturbed air? Suppose a fox or hare runs through a field of infected plants, and then goes off to non-infected districts, he will carry tens of thousands of spores in his coat. Suppose a bird alights amongst infected Potatoes, when that bird flies off he will carry tens of thousands of spores in his wings, and discharge them into the air as he sails over the country or the sea. The innumerable beetles, flies, moths, butterflies, and grubs found amongst Potato plants commonly swarm with spores. When a farmer goes into his infected fields he inhales the spores into his lungs, and when he eats his fruit from the walls of his kitchen garden he takes the spores into his stomach. From the above it will be clearly seen that any idea whatever founded on stamping out, can only be a wild dream."

The above will at least have as much weight as extracts from the daily press, written possibly by penny-a-liners who have no practical acquaintance with the subject on which they write so glibly. I have at the special invitation of the "author" read the book more carefully, and, I may add, have enjoyed the reading of it, but I much fear I shall not be a sack of Potatoes better for all it contains. Still, paradoxical as it may appear, I consider it cheap at a shilling.—A LINCOLNSHIRE POTATO GROWER.

FRUIT HOUSES.

Vines.—Late Grapes should now be ripe, and they will then keep satisfactorily, but if there is any doubt as to their maturity employ fire heat till they are fully ripe. Thin-skinned varieties of Grapes such as Black Hamburgs, &c., will at this season require examining frequently, removing all decayed berries. Damp should be expelled and prevented as much as possible by occasional fire heat by day with free ventilation; night firing should be avoided. Intermediate houses will now be nearly cleared of their crops, and if the wood is not ripening freely fire heat should be employed in the day, but turned off at night. Divest them of laterals down to the principal buds, and check all lateral growths by close pinching. Similar remarks apply to young Vines not having borne fruit but which are expected to fruit next season, taking care in the removal of the laterals not to injure the old leaves. Give every attention to young Vines that were planted this spring; keep the foliage clean, remove all laterals, and maintain a warm atmosphere with a free circulation of air until the canes are thoroughly ripe. Vines in pots intended for early forcing should now be cut back to a length of 6 to 8 feet, placing the plants in a cool, dry, airy position for a season of rest.

Peaches and Nectarines.—When the fruit has been gathered in the late houses the next important object is to secure the ripening of the wood. This can best be done by thinning out unnecessary shoots in addition to those which have borne fruit, the latter being cut out to a successional shoot at the base, and the former being thinned wherever overcrowded. In the case of strong vigorous growths it may be necessary to accelerate the ripening of the wood by gentle fire heat, especially in dull weather, at the same time admitting air freely. Some of the late Peaches, as Dese Tardive, Walburton Admirable, Princess of Wales, &c., in cold localities will require gentle fire heat to ripen them thoroughly. An occasional syringing will be necessary for trees from which the fruit has been gathered. Trees not in a satisfactory condition should, as soon as the wood is mature, be partially or wholly lifted. If this be done whilst the trees are in leaf the house should be shaded before commencing operations, and the old border made thoroughly moist. In removing the old soil com-

mence at the point most distant and work towards the trees, and when it has been cleared away the exposed roots should be drawn aside, damped, and covered with mats whilst the drainage is being attended to; this should consist of 9 inches thickness of rubble, and be covered with turves grass side downwards. Fill in with strong loam, and if calcareous it may not be necessary to add lime rubbish, though a tenth of that material will be beneficial in most cases, and a twentieth of charred refuse. This should be rammed very firmly; and the roots, after having any strong fibreless portions shortened with a knife, must be spread out evenly over the bed, covering them with soil as they are laid out, and when all are covered give a good supply of water at a temperature of 80° to 90°; the remainder of the soil may then be placed on the roots, but they should not be covered deeper than 6 inches. The shading must remain on if the weather be bright, and afford ventilation by the top lights only, syringing the foliage morning and afternoon until it is seen that the roots are working in the fresh compost, when the shading may be removed and the house opened. The trees will rest and be in capital order for forcing when required. They rarely cast their buds after being lifted, and the flowers set better; indeed the operation of lifting is very commendable but too little practised. Trees in good health will not require lifting, but it is a good practice, especially for old trees, to remove the soil from the surface and supply fresh compost, as the roots will benefit by it, adding to their vigour and the size and quality of the fruit produced. When Peaches and Nectarines are forced early in pots they must now be attended to in top-dressing or repotting; these should be done whilst the trees are in leaf, so that fresh rootlets may be produced before the leaves fall. For either purpose the loam must be strong and calcareous, sandy loam being of no use. Should the trees, from having been in pots some years, require renovation, they may be turned out and the ball reduced with an iron prong, returning to the same size pot or one that will admit of an inch or two of additional fresh compost. The soil cannot be rammed too firmly. The trees should be retained under glass until the foliage is mature, when they may be placed outdoors.

ORCHARD HOUSE.

It is of the greatest importance that the wood of all fruit trees be properly ripened, and as soon as the fruit is gathered all superfluous shoots should be at once cut out, so as to admit to the remaining shoots and spurs as great an amount of light and air as possible. Any trees that have been placed outdoors and have not ripened the wood satisfactorily should be returned to the house, in order that the ripening process may be accelerated by a comparatively dry atmosphere. The ventilators should be open night and day, and occasionally syringe trees that have borne fruit to cleanse the foliage of dust and insects. Fig trees in pots showing a good second crop of fruit may be removed to a house or pit where they can be assisted with artificial heat, and be well supplied with liquid manure to enable them to swell off and ripen the fruit. Most other kinds of fruit will have been gathered except the late varieties of Peaches and Plums, and these should at once be potted if necessary, not waiting, as is too often done, until the leaves have fallen; but by potting as soon as the fruit is gathered active roots will be abundant before the leaves fall.

PLANT HOUSES.

Stove.—The first batch of Poinsettias should now be placed in the stove, where they can be accommodated with a temperature of 60° to 65° at night, keeping them near to the glass and feeding with liquid manure. These should be the strongest, and if well attended to they will make a fine display. The weakest plants should be brought on slowly in a temperature of about 55° at night, affording water only to prevent the loss of the lower leaves; they will flower later and be very useful. Euphorbia jacquiniæflora must not be allowed to remain too long in a cool house or the roots will perish, 50° to 55° being quite low enough, care being taken not to supply too much water. Centropogons should only have sufficient water to keep the foliage in good condition, feeding with liquid manure, as this will not only promote the production of large heads of bloom, but will induce a strong second flowering from the upper joints after the principal terminal growths have flowered. Some plants of Plumbago coccinea superba and P. rosea should be kept at the coolest end of the stove,

so as to secure a succession of flowers; the earliest-flowered will start from the upper joints and flower from each. *Sericographis Ghiesbreghtiana* must be in a moist warm atmosphere and a light position to induce free flowering.

The attractive plant *Lasiandra macrantha* produces its beautiful purple flowers in clusters from the points of the shoots at this time of year onwards. Being of straggling habit the plant should be treated as a climber, and though its flowers are of short duration they are produced in great numbers. It succeeds in peat and loam in an intermediate house or cool stove. *Lasiandra macrantha floribunda*, though dwarfer and free flowering, cannot be compared with the species when treated as a climber. Larger stove plants, such as *Ixoras*, that have flowers to open, should be preserved as long as possible, not syringing them overhead more than is necessary to keep down insects, as too much moisture at this season may cause the flower buds to drop. *Dipladenias* and *Allamandas* that have many flower buds should only have sufficient water to keep the plant from flagging. *Bougainvillea glabra* and *Rondeletias* should be treated similarly, and they will afford very acceptable flowers for some time to come.

Amaryllises.—Beautiful free-flowering plants as these are, they do not receive the attention they deserve. Occupying little space and succeeding with fair treatment, they are worthy the notice of all who have a house kept at stove temperature or an intermediate house. They flower over a lengthened period. *Hippeastrum pardinum* flowers with regularity in the autumn and winter, and many early in the year. All *Amaryllids* require a long season of rest, not "drying off," but such as will thoroughly ripen the growths and induce flowering. Both the deciduous and evergreen (*Hippeastrum*) forms will ere this have completed the growth and will need rest. Gradually withhold water, not at any time allowing them to become dust dry, but supply sufficient water to keep the soil moderately moist, and there will be a marked difference at the time of flowering between the plants so treated and those kept as "dry as dust" through the winter. The deciduous forms may be wintered in a temperature of 50°, but the others should be kept a little warmer, 55° being sufficient. *Urceolina aurea* requires similar treatment to *Amaryllis*, and though it is deciduous must not be allowed to become dry at that season, as it throws up its flower scapes when leafless, and usually in October, its pendant yellow green-tipped flowers being very beautiful. Roman Hyacinths, Paper White and Double Roman Narcissus, that were potted some weeks ago may, as soon as they are rooted, be moved into heat to have them in flower early, placing near the glass, so as to render them as dwarf as possible.

Aquatic plants—though interesting, easily grown, and flowering over a lengthened period—are seldom seen, and apart from the beauty of the flowers on the plants they are very useful for cutting for the base of stands for table decoration, particularly *Nymphaea caerulea*, *N. cyanea*, *N. dentata*, *N. Devoniana*, and *N. rubra*. *Nelumbium speciosum*, *Limncharis Humboldti*, *Pontederia cordata*, and *P. crassipes* are very pretty, but *Nymphaeas* are the best. Good turfy rather strong loam, 12 inches in depth, will answer their requirements, and a little more than that depth of water. A tank about 12 feet in diameter will be sufficient for a number of varieties.

Orchids.—Now the weather has become cooler the night temperature may be reduced 5°, a high night temperature being less beneficial than a low one. Regulate the moisture according to the requirements of the plants. As many plants have now completed their growth water must be given very sparingly, being careful not to damp the crown of the plants. Plants on blocks will still require syringing, and those in a growing state will need to have their roots well moistened every morning either by syringing or dipping. Those having the growth completed will require damping every two or three days, the cultivator being guided by the state of the atmosphere the plants are grown in. It is natural for some Orchids to grow now. These should be placed in the most favourable part of the house, and encouraged to grow without check. Air should be admitted according to the state of the weather; when calm and mild plenty of air should be admitted. Many *Oncidiums* and *Odontoglossums* are growing freely, and should have plenty of moisture. They will

need careful watching for thrips, which soon seriously injure the young shoots. Fumigating on three or four alternate nights moderately will destroy them. Cease damping the floor of the *Cattleya* house after the middle of the day. Delay no longer the thorough cleaning of the houses inside and out, washing the rafters and every particle of wood with hot water and soft soap, and the glass with water, it not being possible to have the glass too transparent nor the house generally too clean.

NOTES ON VILLA AND SUBURBAN GARDENING.

KITCHEN GARDEN.

Tomatoes.—The very general heavy rains will have the effect of fast spreading the disease, which has already been very destructive in some districts. The only way to save the whole or part of the crop is to cut off the bunches of all fully grown fruit, whether changing colour or not, and to hang them up to ripen in some warm position. Where plant stoves are available they are suitable, but those who do not possess a heated structure had better hang the fruit in the kitchen. This early cutting of the fruit will entail the sacrifice of many that are only half grown, but probably if the crop is left to ripen naturally the whole will be lost, so rapidly does the disease spread.

Make another sowing of the hardiest varieties of Lettuce to stand through the winter, in case the plants from the first sowing become too large to withstand the frost. If the first sowing of Cauliflower is a failure sow in boxes in a cold frame, and prick out young plants produced either in boxes or in a cold frame in which they are to be wintered. Every attempt should be made to secure Cauliflower plants in the autumn, as in most gardens they cannot well be dispensed with, as they are required to keep up the supply when the late Broccoli are finished. Turnips should be thinned gradually, as they have enemies at all their early stages of growth, and if thinned to the proper distance in the first instance blanks very probably will occur. A dusting of soot and lime will keep off birds and flies, and, during showery weather especially, frequent dustings of the same mixture are necessary in some districts to ward off the fly, which deposits eggs in the hearts when they are "bulbing," followed by a grub which ultimately destroys the Turnips. Thin finally to about 10 inches or 12 inches apart if good-sized roots are required. A sowing made at this time will give a crop of greens if nothing else. Thin late-sown Carrots to about 4 inches apart. Earth up Celery when necessary, selecting a dry day for the operation. Draw earth up to the stems of Broccoli and winter greens in order to steady them, and this will also help to protect them. To blanch Leeks earth up as much as possible without the soil working down the inner side of the leaves. Those sown in the open, however, are scarcely forward enough for this operation. Thin these out to about 8 or 9 inches apart, and as they cannot well be too big give them an abundance of liquid manure. Keep runners pinched off all the Strawberries, and on all favourable occasions hoe among them and all other growing crops. Caterpillars are unusually destructive among Cauliflowers, Broccoli, and Cabbage; hand-picking persisted in seems the only remedy.

HOUSES AND FRAMES.

Where Grapes are at all backward in ripening, or are found to be deficient in sugar, they will be much benefited if the fires are started in the morning of dull days, and on fine days in the afternoon. Have the ventilators open slightly all night both at the top and bottom, and ventilate freely in the daytime during favourable weather, the object being the maintenance of the necessary dry atmosphere, which will materially assist in the thorough ripening of the wood.

Preparations will now have to be made to bring in all the usual occupants of the vineries and greenhouses, as damp cold weather will injure them if they remain out much longer. If the Grapes are thoroughly ripe, and are required to keep any length of time, they may be cut with two or three joints of wood attached below the bunches, these to be trimmed and inserted in bottles partially filled with water and suspended in a dry room. Soda water or seltzer water bottles are suitable, and should not be more than three parts filled. The only alternative of cutting is the free use of fire heat

with ventilation as above advised, as it is useless attempting to keep Grapes in a cold damp house filled with plants, and there are but few small gardens where the vineries can be kept clear of plants. Azaleas, Camellias, Heaths, Epacris, Coronillas, Deutzias, Spiræas, and Chrysanthemums will do well in a dry, cool, or warm atmosphere as the case may be, and may be therefore placed in the vinery. Salvias, Eupatoriums, Libonias, Solanums, Browallias, Petunias, Zonal Pelargoniums specially prepared for autumn flowering, Salvias, Callas, Abutilons, and softwooded plants generally, will do best in the greenhouse. Rather than any of the above useful kinds should be crowded Coluses, Balsams, and even Fuchsias if over-abundant, should be thrown away to make room, as none of them would present a fresh appearance much longer. Better results will be obtained by growing a few good healthy plants than a number of weakly specimens.

Those who intend attempting to keep Coleuses and Iresines through the winter in houses in which a somewhat low and therefore unsuitable temperature is maintained, should select some of the smaller plants, say in 5-inch pots, and well established, placing them in the warmest and driest part of the house. Water must be given them very sparingly and always chilled, and the foliage be kept as dry as possible. They have been kept alive through some winters in the windows of living rooms by those who failed to keep them in a greenhouse, but much trouble was necessarily taken with them. Winter-flowering Begonias, such as *B. fuchsioides*, *B. Digswelliana*, *B. Ingramii*, *B. Saundersii*, and *B. semperflorens*, are sometimes seen in very good condition in imperfectly heated structures. These plants must also be well established in rather small pots and watered carefully, though not allowed to become dust-dry, as that would be very injurious. The proper place for the large-flowering Pelargoniums during the winter is on shelves near the glass. Not much water should be given them.

Cyclamen persicum.—The present is the best time to make a sowing of these in order to obtain sturdy plants with which to make an early start next spring for blooming the following autumn. Fill one or more 6-inch pots half full of potsherds, over this place a little rough soil, filling up to near the top with fine and rather light sandy soil. Sow the seed thinly, press it in, cover lightly with fine soil, and water through a fine-rose pot. Cover the pots with slips of glass and place them on a greenhouse shelf, shade from bright sunshine, keep the soil uniformly moist, and a successful germination will be almost certain.

TRADE CATALOGUES RECEIVED.

E. G. Henderson & Son, Maida Vale, London.—*Catalogue of Bulbs.*
J. B. A. Deleuil, Rue Paradis, Marseilles.—*List of Bulbous and Tuberous Plants.*
George Cooling & Son, Bath.—*List of Bulbs.*
Harrison & Sons, Leicester.—*Catalogue of Bulbs and Flower Roots.*
R. Pennell & Son, 169, High Street, Lincoln.—*Catalogue of Bulbs.*

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Eryngium maritimum (M. E. H.).—The Sea Holly is a perennial plant, and usually succeeds in a slight sandy soil; but possibly your specimens have suffered in the transplantation. The only remedial measure we can suggest is to supply them with a weak solution of salt, as possibly the soil in which they are planted is deficient in saline substances. As the plant is a native of the seacoast in various parts of Britain more or less salt must enter into its constitution.

Brown and Tait's Eclipse Cauliflower (J. G.).—We have had other testimony besides your own of the usefulness of this variety for culture and use

during the summer, and the heads that you sent to us last year quite substantiated all you had said regarding the variety. If other writers on gardening had produced similar heads in a dry district they would have been fully justified in writing approvingly of the variety, and no doubt would have readily done so.

Gardener Emigrating (*Emigrant*).—We regret that we are unable to supply you with the information you require. Some of the principal nurserymen have occasional applications for men to take the charge of gardens in America and the colonies. If you are personally known by any influential nurseryman you might make your wants known to him; failing this your only course will be to advertise either in British or colonial horticultural papers, or both.

Benham Hybrid Melon (*Old Subscriber*).—This Melon, Mr. Howe, the raiser of it, informs us, is the result of a cross between Victory of Bath and Golden Queen. There is, however, a Melon named Scarlet Queen, which Mr. Howe also possesses.

Old v. Gilbert's Victory of Bath Melons (*Idem*).—The Melon exhibited by Mr. Goodacre of Elvaston at the Alexandra Palace was named "Old Victory of Bath," a variety that he had many years ago from Taunton. We do not know what difference there is between the "old" and Gilbert's Victory, and curiously enough a letter is now before us from a cultivator who states he has grown both the Melons named, of which he obtained seed from original sources, and can find no difference whatever between them. The name of the Onion to which you refer was correctly given on page 236. The naming of products at exhibitions is not always so clear as it should be. It is of great importance that new varieties be clearly and legibly named when they are first exhibited.

Begonia Leaves Blistering (*Gloucester*).—Without knowing anything about the conditions under which your Begonias were grown, and the mode of culture pursued, we are unable to suggest the cause of the plants being in their present unsatisfactory condition. The crumpled and blistered foliage may arise from defective root-action, diseased tubers, or sudden fluctuations of temperature. Possibly, however, the evil is at the roots; the tubers may have been slightly diseased, and the plants may have been overwatered during their early stages of growth.

Storing Potatoes (*F. M. S.*).—After many years' experience we have concluded that there is no better mode than storing them in a dry outhouse in layers, alternating with sand, and covered with sand or soil to exclude frost. If you have no such convenience for wintering the tubers you can only adopt the mode of storing recommended to a correspondent last week on page 269.

Late Roses (*Freemason*).—Most of the best Hybrid Perpetuals are good late bloomers, but the particular period at which they bloom depends partly on the time of pruning, and much more on the state of the weather. The following are good varieties and autumnal bloomers:—Charles Lefebvre, Alfred Colomb, Louis Van Houtte, Star of Waltham, Madame Lacharme, La France, Prince Camille de Rohan, Maréchal Niel, Gloire de Dijon, Marie Rady, Beauty of Waltham, and Alfred K. Williams.

Plants for Baskets (*S. H.*).—We do not think that the temperature would be too low for Tropæolums of the Lobbianum species, except, perhaps, during the depth of winter. Tuberous Begonias are bright and effective basket plants during the summer, also Ivy-leaved Pelargoniums, so also are Achimenes. In the spring the baskets may be rendered very gay with bulbs, as Hyacinths, Tulips, &c., succeed admirably in them. Lachenalias are fine in baskets, the bulbs being placed close together all round the moss-lined sides, the centre being filled with rough soil. Mr. Ollerhead of Wimbledon has several baskets thus filled every year, and they are most beautiful in spring.

Fruit Tree Barren (*A. H.*).—Unripened wood is no doubt the cause of your trees not producing fruit, or possibly the frosts of spring have destroyed the blossom. We do not perceive that there has been any fault in the planting, while the soil appears favourable to the growth of the trees. If you have thinned out the growths where they were crowded according to instructions that have been given in the Journal, the shoots remaining will have become firm and mature, and your trees will, in all probability, bear well next year, unless late spring frosts destroy the blossoms. For destroying the insects dissolve 5 or 6 ozs. of soft soap in a gallon of water, adding thereto a wineglassful of paraffin, and apply it to the stems with a stiff brush, scrubbing the solution well into the crevices of the bark.

Hyacinthus candicans—**Planting Agapanthus** (*Mrs. Davie*).—If you have no glass structure to which you can apply artificial heat you had better let the seedlings remain as they are, watering them carefully so as to keep them growing as long as possible. Had you a heated structure we should advise you to prick them off and keep them growing on a light shelf near the glass; but to divide them now without such convenience would probably end in the loss of many of them. You would have succeeded better by preserving the seed and sowing it in the spring. On the approach of warm weather you may divide your seedlings, transplanting them thinly in large pots, or in light soil in a frame. In all probability your Agapanthus would succeed planted out in a warm sheltered border, affording a little protection during winter, which we presume is not usually very severe in your district; but we should not turn the plant out until the spring.

Woodlice in Peach Wall (*J. P.*).—Either all the joints should be carefully "picked out" and the courses freshly "pointed," or the wall should be plastered. If you adopt either of these remedies, and also remove much of the surface soil from the border, especially near the wall, and apply fresh and rather heavy loam, you will at the same time practically eradicate the pests and improve the condition of your Peach trees. A great number of the woodlice may be caught by placing a holed potato in a small flower pot and covering it with moss. A number of traps so prepared and placed on their sides will attract many of the pests. The pots must be examined daily and the woodlice destroyed; but the radical remedy in your case is to carry out our recommendations as to pointing the wall and removing the soil.

Flowers for Cutting (*J. C.*).—We do not think you would find it profitable to attempt growing under the shade of Vines plants for affording cut flowers from June to September. Probably if you had a number of Tea and other Roses in pots they would afford some flowers that would be acceptable, the plants being placed in the open air to make their growth after the flowers were cut. Maréchal Niel would not succeed well on the shaded hack wall. Why not grow a number of Tea and other Roses in the open air for producing flowers during the period named? No plants succeed under Vines better than Camellias, and flowers of the white varieties are always in request. White Chrysanthemums are in demand in the autumn, and a number of plants of Mrs.

George Rundle and Elaine grown in the open air during the summer and placed in the vinery in October would probably occupy the space profitably.

Propagating Fuchsias (J. B.).—You will not be able to strike the young growths at this season of the year without artificial heat, and if you were they would not make good plants, as you have not the means at your command for growing them on properly. You had better gradually withhold water from the plants and permit the leaves to fall; the plants may then be preserved in a light or dark frost-proof place during the winter, the soil only being kept just moist. If they are pruned closely in the spring, and when growth commences have all or nearly all the old soil shaken from the roots and repotted in fresh compost, they will grow freely, afford good cuttings that you can strike readily, and both old and young plants will grow well and flower freely. The growths of your Rose will be better trained to wires about 6 inches from the glass than secured to the sashes, and it would probably succeed better if planted outside the house, the growths being trained inside after the manner of Vines. In this case, however, as with Vines, it is necessary to protect the stem from severe frost by enwrapping it in haybands.

Arrangement of Greenhouse (A. D.).—You do not state the width of the house; but judging from the fact that you have borders of the width of 8 feet, we think you have room for a central stage with a path in front between the stage and the low border, and a narrow path at the back for opening the ventilators. You might reduce the front border if necessary, while the back border we should clear away, and form a flat stage a foot wide 4 feet from the ground; on this you could place tall-growing plants, and train such as are suitable to the wall. For attending to these plants and the ventilators a path 2 feet wide would be sufficient. The back of the stand or stage should be perpendicular, and the top a little higher than the stage near the back wall. The height, however, of both these stages can only be determined by the height and size of the house. The principal stage will slope to the front, the bottom shelf being about 2½ feet from the ground. You might, whether you decrease the width of the front bed or not, raise it a foot or even more to make it more uniform with the height of the stage on the opposite side of the front path, which should not be less than 3 feet in width. The front bed would be suitable for dwarf plants, which would thrive well near the glass, the taller plants being arranged on the stage. You will need a path along at least one end of the house. If the ground, from the wall to the back of the stage, is raised a foot or more, the ascent being by a couple of steps, it might be more convenient for attending to the plants at the top of the stage, which may be 2 feet wide, for accommodating large plants. But this path elevation must depend entirely on the height of the house and the central stand. As you do not give the dimensions of the structure our reply can only be of a suggestive character; it may, however, be of some use to you.

Vines Starting Prematurely (J. H., Bacup).—You have scarcely made your case clear to us, inasmuch as you do not state whether you have pruned the Vines or not. If you pruned them in July you erred; if you did not prune them we cannot understand how they could "start afresh and show bunches" now, unless the growth is in the form of sub-laterals, which not unfrequently show fruit in the autumn, the axillary buds on the primary laterals remaining dormant. If your Vines are pruned and the fresh growth starts from the spurs close to the main rods, all you can do is to train the rods to the roof, manage the house as to moisture and temperature as if in spring, and with proper attention to the Vines (the same as is given in spring) you will have new ripe Grapes soon after Christmas. If the Vines have not been pruned, and the young growths to which you refer are produced at the extremities of the laterals, the base buds remaining dormant, then you may rub off the young growths, keep the Vines as cool as possible by shading them, and dry by sheltering them from the rains, to prevent the primary buds on the lower parts of the principal laterals starting before the time you require them.

Propagating Hollyhocks (Saxring).—Probably if some of the sturdy offsets were potted now and placed in a frame they would emit roots, but the usual time of striking cuttings is in the spring, taking off the shoots when 5 or 6 inches long with a heel, and inserting them singly in small pots and plunging them in slight bottom heat. You may also divide the plants in spring, or rather take the offsets from them with some roots attached, and plant them where required to flower. Hollyhocks are also propagated from eyes or cuttings in the summer. These cuttings are made from medium-sized or small flowering stems where they are a little firm, and a small leaf is produced from each joint. If cut smoothly close under a joint and slanting an inch above it, and these "eyes" are inserted firmly in sand under handlights, watered and shaded to keep the leaves fresh, roots will soon be emitted and growth issue from the axil of the leaf from which the flower bud has been removed. Cuttings have two joints, the lower being inserted in the soil to produce roots, the upper being just above the soil to produce growth. This mode of increase may be adopted in June or July. If you can take offsets from the plants now with roots attached, pot and place them in a frame, that would be a sure mode of increasing your stock; but when a great number of plants are required the other modes of propagation are resorted to.

Grapes Decaying (C. Edwards).—The Grapes were quite smashed by having been sent loosely in a tin box. Fruit should always be packed so that it is immovable in transit. We have no difficulty, however, in determining that the bunches are much shanked, and judging from the general appearance of the stalks we have no doubt that the root-action of your Vines is defective. If the border is wet it must be drained, and the old soil should be removed from the roots and fresh turfy loam applied. You state no particulars as to the age and growth of the Vines. They probably require renovating, and if so you cannot do better than adopt the plan described on page 227 of our issue of the 9th inst. There are hundreds of old Vines in the country that might be greatly improved if the mode of renovation there detailed were carefully carried out. There is no better time for lifting the roots than the present, or immediately after the crops are cut, and before the leaves fall from the Vines.

Vines in Low Situation (G. D.).—We think you may reasonably expect to produce good Grapes under the conditions you name, provided—and this is very important—that you keep the feeding roots near the surface of the border by mulching with manure, especially in summer. If you do that and water occasionally in dry weather, the moisture and rich food will not render it necessary for the roots to descend into the subsoil in search of the moisture they need and will find if it is possible, which in your case they will have no difficulty in doing. If you neglect the surface of the border by permitting it to become dry in the summer the roots will inevitably descend, and then your Vines will not long remain in a satisfactory condition. Had we been consulted before the border was made, we should have advised you to make it entirely above the ground level of the district, and then if you had concreted the bottom you would have been quite safe from the stagnant moisture that exists below the peat bed. Follow the course we have recommended of mulching the border with manure to remain on all the summer, and then, if the Vines diminish in fruitfulness after

a few years, lift the roots and place them in fresh and good soil, making the border as we have indicated.

Plants to Flower in August (L. D.).—Allamanda Hendersoni should now be kept rather dry at the roots, and in plenty of light, so as to ensure the thorough ripening of the wood. It should be kept rather cool and dry through the winter, but not so dry as to cause the wood to shrivel, and should be pruned and started early in April. Anthurium Schertzerianum will require ordinary treatment up to March, when it must be kept cool, or in a temperature of 50° artificially, and about the middle of June should be placed in the stove and encouraged with plenty of heat and moisture; whilst resting it must be comparatively dry. Bougainvillea glabra should be kept cool and dry up to June, when it must be pruned and started in heat. Clerodendron Balfourianum also should be similarly treated until June, and then started, not bringing it on too quickly. Rondeletia speciosa major being pruned and started early in April will flower at the time required. Statice profusa will also require to be cool and as dry as the foliage will bear up to July, when if placed in moderate heat it will come on gradually. Stephanotis floribunda should not be started until May, and may then be brought gently forward. The present condition of the plants will exercise an effect on the flowering, but it is a question of retarding the flowering to a later period than usual, and requires considerable experience and judgment on the part of the cultivator. Some started at the time named may come into bloom too early, and will need to be retarded, and others may need assisting, which can only be ascertained by the grower.

Names of Fruits (George Seales).—The Apple is Alfriston.

Names of Plants (Northampton).—1, Gymnogramma chrysophylla; 2, Gymnogramma peruviana; 3, Platyloma falcata. (N. S., Bristol).—Lyccesteria formosa. (J. Send fronds of the other Ferns bearing spores.

POULTRY, PIGEON, AND BEE CHRONICLE.

SHED ACCOMMODATION FOR CATTLE.

(Continued from page 271.)

IN making further allusion to the accommodation for cattle we must observe that our remarks upon box feeding have not included any statement as to the value of the manure obtained in boxes compared with other modes of securing it. The quantity of dung, including both liquid and solid excrement voided by cattle, may be estimated to weigh about 80 lbs. daily; and if box feeding will retain for use more of this than any other method it becomes a matter of some consequence, particularly as the value of the dung voided by full-grown animals, whether dairy cows or fattening cattle, would, according to the nature of the food consumed, vary from 1s. 6d. to 2s. 3d. per week per head of stock. Various interesting experiments have proved these items to correctly represent the result of box feeding if properly carried out. We also find that when 20 lbs. weight of straw is used as litter it will yield of well-made manure four and a half times increase, or 90 lbs. weight of fresh box dung. It is further considered that twice as much litter must be employed per head when animals are fed in open yards and sheds. Assuming this to be the case, and supposing the weight of fresh dung to bear the same proportion to that of the litter in both cases, it is clear that a given amount of litter used in open yards will be saturated with only about half as much of the excrements of animals as it would be in boxes, the remainder of the moisture being made up by rain water. At any rate, it is obvious that the amount of the constituents derived from animal excrements that will be carted to the field in each ton of dung will be extremely variable according to the mode of its manufacture. It must, however, be borne in mind that to obtain the full value of box-made manure it should be laid upon the land direct from the pit.

Buildings for stall feeding next claim our attention, for practically this is the only mode of caring for cattle under cover available in the pasture districts of the kingdom. The scarcity and dearness of straw renders box feeding almost out of the question. We have, however, to deal with two important objects in this case—the health and comfort of the animals, and the rendering

of their manure valuable for improving the parkland and pastures. It is not often that new erections are required for stalling either fattening bullocks or dairy cows, for almost any range of shedding may be made available at but little cost. If, however, it is required, a lean-to shed of about 16 feet in width may be made to answer a good purpose, being merely attached to some building of sufficient stability. In the apportionment of the 16 feet space inside we shall require a feeding path 3 feet wide; this will leave room for 10 feet of standing room for the cattle and the mangers, and 3 feet for the passage of the animals and the removal of dung. The question of stalling is worth consideration—whether the animals should stand in pairs, with a stall division between each pair, which for large cows or fattening oxen should be not less than $7\frac{1}{2}$ feet apart, but for smaller animals $6\frac{1}{2}$ or 7 feet will be sufficient; the other alternatives are divisions for single animals at about 5 feet apart, or merely a tether without any division at all. We recommend the stalling in pairs, because the animals being tethered on each side can feed separately without interfering with each other, nor can they turn round and drop dung on the part assigned for their bed. Now, the saving of the manure in a useful state must next be considered; and on being asked, Will it pay the expenses of collecting, preparing, &c.? we say Yes, if we calculate both the direct and indirect advantages of the system, taking as direct the value and quantity of dung as above stated, and the saving also of straw as litter; then indirectly the advantages of the animals living in a pure atmosphere are of the highest importance. The mode of saving the excrement, both liquid and solid, which arises at the stalls may be done in different ways. First the floor of the stalls should not be composed of brick, stone, or any materials which will absorb and retain the urine in or between them, because they will be continually giving off ammonia and tainting the air more or less, except in the case of an earth floor, which will absorb the urine and fix and deodorise the ammonia and other volatile portions of the manure. There are only a few cases, however, in which we advocate the use of an earth floor to the stalls, one of which is for dairy cows that are only in them at milking time or in bad weather, and this exception is justifiable only in consequence of the earth floor, which when used constantly without litter would require removal too often for economy, the solid excrement only being removed in the same way as required from stalls with an impervious floor. A floor, however, made of concrete should have a fall to the gutter behind the animals for the urine to drain away to a tank, giving proper attention to cleanliness in the stalls. The urine or liquid manure should be treated in the tank with some absorbent materials, such as dried and screened earth, strong loam being the best, or otherwise dried peat soil, or dry and charred ashes, all of which will answer the purpose of securing the value of the manure as a good dressing for pastures, &c. On no account must the liquid remain on the surface of the accumulations in the tank, because fermentation and decomposition will immediately take place, not only reducing the value of the compost, but tainting the atmosphere of the contiguous sheds and stalls. In removing the solid excrement it may be cast into the tank if sufficiently capacious, otherwise it should be placed on a heap of dry mould under cover, in which case, after being turned over and mixed, it will form a manure superior to that when mixed with straw litter. Another way of disposing of the liquid and solid manure is to flush it away together with water into a tank, to be used on Mr. Mechi and Mr. Hustable's plan for being distributed by pump and hose over the land; but we do not advocate this. Another plan is to have a trench or pit about 3 feet wide and 2 feet deep covered with a sparred floor or grating behind the animals; the manure then drops directly upon the grating, and passes into the pit, which should be partially filled with absorbent materials at intervals as above stated, and the sparred floor kept clean by sweeping and using gypsum strewn over. Now, any of these plans will accommodate either dairy cattle or fattening bullocks without being likely to endanger their health or injure the milk for dairy purposes, yet it must be remembered that the manure arising from fattening bullocks will pay better for careful attention in its preservation than that derived from the dairy cattle.

Having referred to the housing of cattle on pasture farms we will notice the system adopted by arable land farmers, which is practised in various counties, but especially in Norfolk. It is, however, upon occupations generally where the farmer is debarred from selling any of his straw; he in consequence follows a plan which will readily and at little expense convert the extra straw into useful manure. Now, although the home farmer may have a considerable portion of arable land produce in straw to convert into manure, yet he is not bound to do so, but may sell it. We shall, however, remark on "Hammell" or court accommoda-

tion as used in Norfolk and other districts, for although it does not meet our approval entirely for fattening bullocks, yet it may be used with some advantage for young stock in the winter months, and more especially those which are kept in what may be termed a probationary state, in readiness for entering upon pasture feeding, and to be fattened thereon in the summer months. These courts consist of a lengthened shed divided into compartments, to contain easily from three to four beasts, with a doorway to each which opens into small uncovered yards. Some farmers feed the animals in the shed, others feed them with moveable racks and troughs outside, and it is contended that as the fattening animals get moderate exercise it keeps them healthy without hindering their fattening, and also that the cost of attendance is less than on the stall system, and the dung being constantly covered over with fresh litter instead of being removed. It is not, however, customary with them to place earth on the floor of the sheds and open courts; but the home farmer will readily see the advantage of doing so if he should be induced to adopt this system with his young cattle, but for fattening bullocks all the arguments referring to it are dead against the "Hammell" system. As this is a question of vital importance upon any home farm we recommend that where there is nearly all parkland or pasture that a fair portion of arable should be held with it, in order that a fair amount of straw produce may be grown for the purpose of littering stock of various ages, or for various objects. In most cases—whether of dairy cows, fattening oxen, or the calves and young stock reared—some litter will be required, especially in the case of calves and yearlings, for although these can be managed on the grass paddock, with sheds for refuge in the summer months, yet in winter, for something like seven months out of the twelve, they will require to be housed or partially sheltered in yards in the night or day according to circumstances. The "Hammell" system will be sufficient for the yearlings, but for calves of any age up to nine or ten months they should be under cover when not grazing on the pastures. Now, for these the boxes or divisions under cover will accommodate them; but it requires the careful management of earth floors, with constant littering with short straw, and fine earth added occasionally, in order to prevent foul air in the pens, for we hold that no calf pens are healthy, or so healthy as when the manure accumulates under them upon the box system, as we have before described. But especially will this be the case with fancy stock, or animals held on for exhibition purposes, upon the principle of early maturity. In fact, for such animals they should never be off the straw, for when kept in boxes three or four together, according to age, there is no accommodation which will bring them forward in better health and more promising condition for exhibition, as we have proved in our practice for many years, whether the animals were shown for prizes or went straight to the butcher for slaughter. Before concluding the subject we shall refer to covered farmsteads, &c.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—The importance of this in various ways after the completion of harvest imposes upon the animals severe work, so many and such beneficial tillages being required, and all crowded into the space between harvest and the middle of October, this being the period at which the preparation of the land by ploughing, pressing, &c., for the Wheat seed time can no longer be delayed without serious risk. There is no way so advantageous as to employ steam power, for it not only does a lot of the heaviest work, but it does it within a given time. This the ordinary horse labour of the farm cannot often accomplish in reasonable time in any season upon heavy soils, much less in an autumn like the present, when there is a heavy amount of horse labour in arrear. We cannot now be too early in ploughing the last time for Wheat, because a stale and mellow furrow is really requisite to insure a good seed bed; but although we recommend an early preparation of the land we do not as a rule recommend sowing Wheat before the middle of October, except under peculiar circumstances of soil, situation, and aspect, when it can only be decided in a general way by those who are experienced in the farming of a particular district. Rye, Trifolium, winter Vetches, winter Beans, winter Barley, &c., should all be sown now, the sooner the better. We have a variety of winter Barley now being offered in the markets which we have not noticed for some time until last year. Nearly or quite fifty years ago we used to sow it as spring food for sheep and cattle. It is even more forward than Rye, and stands the frost well. It does not grow quite so thick as Rye, but is stouter in stalk and more succulent. Cabbage plants of the varieties required for the feeding of stock in the spring can now be planted, for it may so happen that they may be very valuable in a cold dry season, and if not required upon the home farm they are sure to be required by people in towns: in fact, wherever the farms are situated near to populous towns the vegetables produced ought to be of such kinds as are likely to furnish food for the people when the stock of the home farm cannot consume it all in good season.

Now the method of manuring the land is important, and in the event of the soil being strong and heavy the land should be laid into ridges about 8 or 10 feet wide with deep land furrows, so that the water may drain off the surface quickly in order to insure an early growth; but when the soil is dry and friable the plants may be set upon land ploughed on the level, except in case it is very much exposed. We then prefer to plough the land into stretches 18 inches or 20 inches apart, and set the plants in the furrows so that they may be protected against the cutting winds and frosts of winter, and at the same time if a fall of snow lies on the land for some time the plants will be covered and will thus be protected against larks, wood pigeons, and other depredators—even rabbits, for all these enemies to vegetation often destroy such crops as young Cabbage plants during a hard winter. If the land requires it some guano or superphosphate may be strewn in the furrows at planting time, otherwise some other hand manure, nitrate of soda, &c., may be sown in spring at the time of horse-hoeing, which will encourage the growth of the plants.

Hand Labour.—The men will now be required to finish the trimming of hedges. It should, however, be done before this time to be completed at the proper time, also finishing off the corn ricks by thatching and trimming the outsides. For this work the newly invented hedge-clipping implement will answer well and make the ricks look very neat if properly done, for the home farmer should remember that most landowners like to see the ricks and stackyards neat and clean. The underwood in the hedgerows and coppices will now be ripe for cutting, as it makes no further growth after the middle of this month; besides which the rods always work kinder and freer when converted into hoops, &c., whilst the wood is soft and kind. All timber cut for repairs during the spring should now be entirely cleared off the fields or woodlands, and the heavy timber carts, &c., will do but little injury if employed before the autumn rains set in. The dairy cows and also the young stock will now require some supplementary food, such as Clover, as long as it lasts, or late-sown Rape and Vetches, otherwise early Turnips, Cabbages, &c. Where these auxiliaries cannot be obtained an allowance of 2 or 3 lbs. of linseed cake or 3 or 4 lbs. of cotton cake per head should be given daily, as the pastures are now getting stale, except in those cases where grass has been specially reserved for autumn feeding. Now is the time to purchase cows having recently calved, in order to maintain a full supply of milk, &c., for the winter months. The young Clover plants, whether grown in Wheat or Lent corn, may now be fed off by sheep without injury, if not fed down too close, up to the 1st of October; but from that time should be reserved to make a little foliage to protect the crown buds and stems during winter. If the seeds are not very strong it is best not to feed them at all, as they then stand the winter better.

ADVANTAGES OF A HOME FARM.—No. 1.

COUNTRY gentlemen who are landed proprietors are accustomed to retain a farm in their own hands at a convenient distance from their residence for the production of farm produce to supply the wants of their household. The plan is based upon the soundest principles of economy, and when well carried out combines the advantages of a regular supply, produced at the lowest possible cost, of food that is wholesome, fresh, and sweet. Having for some time had the management of an estate upon which this system of home farming is thoroughly and successfully carried out, I purpose giving an account of what is done and how it has been found to answer.

A full supply is maintained throughout the year of milk, cream, butter, eggs, chickens, mutton, bacon, hams, lard, flour, hay, straw, and corn. Pork, Turkeys, Ducks, Geese, and Pigeons are supplied when in season. The main crop of Potatoes, with Carrots, Turnips, and other root crops, is also grown here. I may add in passing, that when to this is added the gamekeeper's usual quantum of game, fish, and venison, a house is rendered almost independent of the butcher and provision merchant.

Of the size of a home farm it is difficult to submit any general positive statement, local peculiarities of climate and soil must always be taken into consideration. A few acres more rather than less than is considered absolutely necessary may always be retained profitably, for the home farmer has the peculiar advantage of a market close at hand for the bulk of his produce, and has no difficulty in the profitable disposal of what is not required for home consumption; for although he has in his annual statement to show clear proof that the farm is paying the popular "three incomes"—the landlord's, the tenant's, and the interest upon capital invested in its culture as well as a surplus to be expended in future improvements, yet he is not obliged to sacrifice his superfluous stock to raise funds for the rent day, but can await each favourable turn in the markets before effecting a sale.

Statements are occasionally published of what wonderful things may be done upon a very limited area of land—how an acre will maintain a cow, and other acres can be made to do something equally wonderful. Tempting as such statements are, they must

always be received with reserve and acted upon with extreme caution. To obtain large returns from farm land a system of high culture akin to that of market gardening must be pursued, and the outlay of capital will be proportionately high. The thing is as clear as the day; it is an expensive high-pressure system always to be avoided when possible, for very high farming only answers under very favourable circumstances.

Two hundred acres may be taken as the maximum size for a large establishment of the first-class, consisting of the family and about thirty servants. For ordinary and more numerous establishments fifty acres less will suffice. At first sight this area may appear in excess of ordinary requirements, but in making calculations a broad margin must be allowed for visiting company, as well as for adverse seasons. Accidents and disease among live stock must also be expected. No produce of inferior quality must be sent to the house; but then it can readily be sold with the surplus, which must always exist in order that the farm may fully sustain its legitimate purpose of keeping up a regular supply. To do this well requires some experience combined with sound judgment and the exercise of a considerable amount of care and forethought. I will next refer to the management of the soil.—EDWARD LUCKHURST.

THE INSECT FOES OF THE MANGOLD WURTZEL.

WRITING upon this important plant, Mr. Dickson stated in 1844 that in the general way it appeared to be little affected by insects or by drought. More extended observations do not sustain this favourable view with regard to insects, for it has been noticed to be liable, not only to the attacks of those insects which infest Beet, but also to several that are only too abundant on the Turnip. One of these, which has done notable damage to the Mangold Wurtzel in several localities, is the grub or larva of the fly known in science as *Anthomyia betæ*, the first account of which was published in Curtis's "Farm Insects" (1860), the species having been observed a few years previously. Mr. Curtis expressed the opinion that it was not a pest likely to do much harm, though he suggested that it might render the leaves of the Mangold Wurtzel unwholesome food for cattle. He thought also that it was a species, the increase of which was held in check by a minute parasite, and, indeed, he was unable to obtain examples of the female insect. In appearance this fly resembles somewhat the Onion fly (*A. ceparum*), which, with the even more abundant Cabbage fly (*A. radicum*), is unpleasantly known in our gardens. The habit of the larva of *A. betæ* is decidedly different from that of the preceding, since it mines the leaves, speedily reducing them to decay, and where thousands are at work in a field it presents a wretched aspect, the remedy suggested by Curtis—viz., the pinching of each leaf the moment it is discovered to contain a larva, being inapplicable on a large scale. This larva is pale green, scarcely a quarter of an inch in length when adult, pointed at the head and rather broad at the tail; it turns to a pupa within the leaf. Curtis thus describes the male fly:—Ashy grey, clothed with black bristly hairs; head semi-orbicular; eyes, large brown; face satiny white, with a bright chestnut-coloured line down the middle; protruding lip and palpi black; wings transparent, tinted with tawny at the base; legs longish and bristly. The female fly has been taken this year and presents some points of difference which will be noted shortly.

Another species of this genus, *Anthomyia grava*, has done some damage on the Continent to Mangold Wurtzel and also to Beet, producing cavities in the bulbs; but though a native of Britain, it has not been yet reported as injurious to our crops. The male fly has a black trunk and legs, an ash-coloured body, with darker bands and black spots. The female is ash-coloured, with a black line down the centre of the body. The size of each is under a quarter of an inch.

The insect commonly but erroneously called the Turnip flea—properly a beetle named *Haltica nemorum*—visits the Mangold Wurtzel. As early as April or May the females deposit their eggs upon the young plants, and the larvæ shortly after are found within winding burrows formed in the pulp of the leaves. They are full grown in less than three weeks, quitting their mines usually to become pupæ. Several broods of these may follow each other in the course of one season.

The larva of another beetle, *Silpha opaea*, did much harm to the Mangold Wurtzel in Ireland during 1844 and some years subsequent. It does not seem to have been particularly noticed in Britain. It is conspicuous, being an external feeder, devouring the leaves down to the root in the months of May and June. Within a mixed field, where grew also Potatoes, Turnips, Peas, and Beans, this larva rejected these to fasten upon the Mangold Wurtzel. Squat in form, with short legs and a black and shining skin, this larva has a near resemblance to a woodlouse; the males, however,

are rather longer and narrower than the females. Salt and lime have been found to have not the slightest effect upon them.

The caterpillars of two moths occasionally frequent our crops of Mangold Wurtzel, and in appearance and habit they have a great resemblance to each other. They are fat brown caterpillars allied to the ever-abundant *Mamestra Brassicae*. One of these produces the Turnip moth (*Agrotis segetum*), the other the Heart and Dart (*A. exclamatoris*). The larvæ of both are hatched in spring, when they at first feed upon the leaves, but shortly burrow underground, where they destroy the roots, often coming forth at night to attack the stem or the crown of the plant. The late Edward Newman remarked that the farmers have brought upon themselves the trouble they have had from these pests by encouraging the destruction of rooks and starlings, their especial enemies. The partridge also seeks them eagerly, particularly the larva of *A. segetum*. Curtis received between 1836 and 1842 many accounts of the damage done to young Mangold Wurtzel by the larva of *A. exclamatoris*.

Our list is not exhausted, for the almost omnivorous larva of the crane fly (*Tipula oleracea*) in some years seriously affects this plant, nor does it always escape the wireworm. Swarms of a minute *Podura*, a jumping mite, are occasionally seen upon the leaves, but they are not harmful.

The most decidedly injurious to the crops during the present year is the pest first named. We saw in July many acres of Mangold Wurtzels without a healthy leaf on them, and the crops were practically ruined. There were millions of maggots in the field. We counted two hundred in the leaves of one plant, and as may be expected they were speedily devoured and the small roots remained in a standstill state. It is difficult to know what course to pursue under those circumstances, but it would be at least prudent to grow the Mangold Wurtzel crops next season as far as possible from the fields that have been so persistently attacked this year.

POULTRY NOTES.

THE DAIRY SHOW.—Owing to the liberality of several donors of money and special prizes the schedule of the Dairy Show is this year a much more liberal one than last year. Dorkings are aided by a gift of £10 from the Rev. H. R. Peel; they have six classes with prizes of £3, £2, and £1 in each. Cochins are shown in pairs and have four classes, Brahmas the same number, Hamburgs five, Game six. There is nothing novel in the poultry schedule save a class for Plymouth Rocks. There are four classes for dead poultry, which are admitted up to ten o'clock on the first day of the Show, and may be removed at 5 P.M. on the third day. The Judges are Messrs. T. C. Burnell, O. E. Cresswell, S. Matthew, R. Teebay, and G. S. Sainsbury. We are particularly pleased to see the name of the last-named gentleman, as the Waterfowl are sure to be most ably judged. We understand that Mr. Cresswell only allowed his name to be put down conditionally—i.e., in case he should be well enough to officiate. For Pigeons there are throughout three prizes of £2, £1, and 10s. in each class; Pouters have seven classes, Carriers nine, Dragoons eight, Tumblers six, Barbs six, Jacobins five, Fantails two, Owls four, Turbits four, Antwerps five, and Nuns, Trumpeters, Magpies, Runts, and Suabians each a single class.

We understand that Mr. A. Darby of Little Ness, Shrewsbury, has been elected to the office of Co-Treasurer of the Poultry Club, vacant by the resignation of the Rev. H. R. Peel.

The Poultry Club is, it is said, likely to hold a show early in January in one of the home counties, open alone to the members of the Club.

We have often advocated the proper subdivision of classes for poultry where several different colours of the same variety otherwise compete together as a politic measure even from a monetary point of view. An analysis of the entries this week at the Worcester Show quite confirms our opinion. Game had four classes and sixty-two entries, Cochins four classes and fifty-seven entries, Brahmas four classes and sixty-nine entries. The five varieties of Hamburgs competed together in two classes, and the result was that seven cockerels and eleven pullets appeared, and this at a place very accessible from the great Hamburg-breeding districts. The Variety class too—to which Malays, Minorcas, Audalusians, Sultans, Silkies, and many other varieties were relegated—contained only seven pairs of birds. Bantams again had six classes (by no means too many), and mustered in consequence ninety-four birds.

DOES LIKE PRODUCE LIKE?

AN applicant for information says, "Does like produce like?" We answer, as we have answered before, "Yes" and "No." In

all admitted breeds, Polands, Cochins, Game, the varieties of Ducks and others that have the stamp of originality upon them, like produces like—not, however, to a feather. The prevalence of dark ones in a Cochin, the brown breast sometimes thrown by the offspring of Black Red Game fowls, and the increase of black feathers in the white top of the Poland continually occur, but nothing beyond this. There is no such thing as breeding Malay from Game, or Dorking from Cochin, or Muscovy from an Aylesbury Duck. Strange things are sometimes heard of; but in those instances there can be no doubt that the birds whence sprung the anomalies were themselves impure and cross-bred, and had thrown back to a distant cross.

If we go beyond our poultry yard, and look among wild kinds, we find this truth borne out. Every species is distinctly separate; and although when domesticated there have been instances of different breeds intermixing, yet the result has always been a hybrid—an animal incapable of increasing or continuing its species. We believe there is no known instance of hybrids in a state of nature. Those most common in a domestic state are between common fowl and Pheasant, ordinary and Muscovy Ducks, Pintail and Wild Ducks, Canada and Barnacle Geese. They have been seen between the Golden and common Pheasant, but very rarely.

Distinguished from these we have a manufactured fowl in the Sebright Bantam. As this is a compound of many varieties of the same species, it retains its productive properties. It is true some difference in shape was desired and achieved; but the main point was feather, or, to speak more correctly, colour. It is hardly necessary to state that every feather is or should be accurately laced, and it was by most skilful and patient combinations accomplished. When, however, these birds are kept apart from all others of the same breed, a few years are sufficient to destroy all beauty; and as to gain certain points it was often necessary to make use of a bird possessing only one of them, joined to positive ugliness in other respects, so, when these birds are left alone, and the combination that made them handsome is not renewed, they seem to lose everything that is pleasing to the eye, and become uglier than any other, showing principally the most objectionable parts only of those birds from which they were made.

In this instance, then, like does not produce like; but the law of Nature shows itself in this as in other things, wise and immutable. One chemist, by a skilful combination of various drugs or minerals, may succeed in forming that which he requires; but if it be left to itself and inspected after a time it will probably be seen the component parts have already divided themselves. Just so in the Sebright Bantams: the two colours, no longer skilfully blended or divided, become patches, the accurate comb becomes a deformity, and the once beautiful breed is to all intents and purposes a mongrel. In a distinct breed—as for instance Cochin or Dorking, no period of interbreeding will cause it to assume the appearance of any other breed. Degeneracy shows itself by stunted growth, crooked limbs, and large joints; its effect on colour is to increase white just in proportion to the growing weakness of the animal. Like produces like in every pure breed; but it is impossible to get one variety from another, unless at some time there had been a mixture of it in the parent.

VARIETIES.

THE HEMEL HEMPSTEAD POULTRY AND PIGEON SHOW.—This Show, which will be held on the 29th and 30th inst., promises to be even more successful than in former years; 650 entries have been made—poultry 405, Pigeons 245. When it is remembered that the poultry must in all cases be birds of 1880, and that in the local classes birds must have been hatched and reared by the exhibitors residing within a radius of twelve miles, the result must be considered very satisfactory. All the classes (fifty-seven) have received the requisite number of ten entries, with the exception of those in the open classes for Hamburgs, Polands, Langshans, Scotch Greys, and Sebright Bantams, which have been erased from the list in accordance with Rule 3; the entry fees with an allowance for post-office order and postage having been duly returned to those exhibitors who made entries in those classes. The local classes have been filled without any exception, and many of the open classes are very strongly represented. The prize money has been deposited in the Bucks and Oxon Bank, and will be forwarded by cheque together with the prize cards, to the successful exhibitors on the day succeeding the Show. Mr. M. Leno will judge in the open classes, *vice* Mr. Cresswell, who retires from the office of Judge, as the Show this year is not held under the rules of the Poultry Club.

— **ROYAL AGRICULTURAL COLLEGE.**—Mr. John Scott has been appointed Professor of Agriculture and Estate Management in the Royal Agricultural College at Cirencester. Mr. Scott studied agriculture at the University of Edinburgh, and has had many years' practical experience in farming, estate management, and land valuing, both at home and in the colonies. He is the author of two well-known books on farm and estate valuations, and was formerly Editor of the *Farm Journal*.

— **EFFECTS OF THE HARVEST.**—Whatever may be the reports about the harvest from different parts of the country, the returns from the Statistical and Corn Department of the Board of Trade are most satisfactory. The price of Wheat, Oats, and Barley was considerably lower last week than it has been for any corresponding week for several years past. The average price of Wheat last week was 39s. 11d. per quarter, or 8s. 2d. per quarter lower than it was for the corresponding week for the preceding four years. The average price of Barley was 33s. 5d., or about 8s. 2d. cheaper; and the average price of Oats was 20s. 7d. per quarter, or about 4s. per quarter lower than it was for the corresponding weeks for the preceding four years.

— **GOAT SHOW.**—The Goat Show at the Alexandra Palace proved a great success, a large number of these interesting and useful animals being exhibited. The first prize for a he Goat was won by a remarkable animal belonging to the Baroness Burdett-Coutts, a Hungarian Goat of great size. Mr. G. Tredgold was placed second with a finely formed animal. The development of the size of Goats is one result which the British Goat Society hopes to attain by the discouragement of too early breeding. Mr. Stephen Holmes Pegler, the Hon. Secretary of the British Goat Society, the Judge at this Show, sent to the Exhibition (though not for competition) a most interesting animal—the Angora or Mohair Goat. Among the foreign Goats were some belonging to Lady Emily Pigott, including a Spanish Goat. Mr. Clarence Bartlett, one of the prizetakers, showed a Nubian Goat. According to Mr. Pegler, who is the author of a book on Goats, these are the "points" to be looked for in a good milch Goat:—She should be "as large as possible in size, with small compact head, broad at the forehead and narrow about the muzzle, eyes large and prominent, the shorter the horns the better (those devoid of any being usually very good milkers), ears large and somewhat pendulous. The hair of the body should be tolerably short, hard, and stiff, and not too abundant. Large teats are almost as essential as a big udder." It was interesting to note the number of Goats coming up to this standard at the Exhibition. One of the finest was shown by Mr. Crookenden, but which only secured a second prize because of its breed not being considered so purely British as Mr. Clark's, which accordingly took the first prize in a class entitled British she Goats. Babylonian, Dutch, and Circassian Goats are exhibited, and a number of kids of different varieties. The Show was ably managed by Mr. Wilson, late of the Crystal Palace.

— **THE SPEAKER ON FARMING.**—At Glynde Harvest Home, on Saturday, the Speaker of the House of Commons gave his annual address to those engaged on his estate. He said he had been a farmer thirty years, and throughout that period had keenly watched the harvest periods from year to year. The weather during the late harvest had been among the best ever enjoyed, so far as his knowledge went. He thought he could speak with confidence in stating that the harvest period of last year was one of the worst on record. He had prepared a statement showing the rainfall, sunshine, and number of rainy days during the months of January to September 1879-80. The facts were very interesting. They showed that in August of last year the fall of rain was nearly 6 inches, while during the corresponding period this year the depth in the district was less than an inch. The average rainfall of the district was rather over 2 inches per month, and therefore the disastrous consequences attending the great additional quantity of rain last year were easily understood, as well as the beneficial effects of the decrease during last month. He feared that 1879 was a most disastrous year to those engaged in agriculture, both owners and occupiers. It was satisfactory, however, to know that while two classes had suffered greatly, those actually

engaged in the cultivation of the land had suffered no diminution in their wages, and they had brought to them supplies of food from all parts of the world at the cheapest rates. There are some who believed the English farmer cannot successfully compete in food production with his rival in the Western World; but he had no misgivings on that score, provided we were blessed with average seasons.

— **THE FOWL OMNIBUS.**—Now that the crops are pretty well carried, and the ground is dry and hard, there is the best chance possible for the farmers' wives to insist upon the institution of a fowl omnibus or two on every farm. This simple and too-much-ignored apparatus consists of a travelling waggon, which may be of almost any shape and size, from that of a railway carriage to that of a bathing machine. A moveable house, such as many gipsies use, would answer the purpose admirably; but nothing is better than the vehicle from which it derives its name, and which is the most durable as well as the most capacious to be found. The inside of the carriage, whatever it may be, is prepared for its new use by being cleared of all its usual fixings and adornments, and provided in the place thereof with a great number of perches fixed crosswise from the roof to within a few feet of the floor, and arranged so that each row is a little on one side of the one above, and not directly beneath it. Upon these perches the fowls roost in rows, and they can be packed very close indeed as long as there is plenty of ventilation at the top, and the floor is well strewn with sand or sawdust. The manner of employing the fowl omnibus is this: As soon as a corn field is cleared of crops it is wheeled out to the stubble with all its occupants safely shut in. The door is then opened, and they either fly or walk down a convenient causeway constructed for the purpose. The stubble affords them not only abundance of food of great variety—both grain, insects, and earthworm—but also a spacious recreation ground over which they roam at large. Towards evening they are said to be always ready to return—tired, but contented—to their shelter, when the door is shut and secured, and the happy family is left in peace till the morning, or wheeled back to the yard if there is any fear of nocturnal thieves. When one pasture ground has been well cleaned a move is made to another, and the chickens are thus kept going for weeks without any expense, and return to the poultry yard in excellent condition for being fattened or even slain at once. The land is at the same time immensely benefited by the clearance of slugs, insects, and grubs which the feathered holiday makers have effected.—(*Irish Farmers' Gazette*.)

— **GUINEA FOWLS.**—The domestic Guinea Fowl in ordinary circumstances can hardly be considered profitable poultry, but its character has nevertheless been considerably belied. We have heard it said that it could not be kept on account of the screeching noise it makes; but we cannot understand how anyone objecting on that ground can abide the noise of an ordinary cock, much less of an ordinary farmyard; since, disagreeable as the cry is (resembling the noise of a creaking axle more than anything else we can think of), it is very seldom heard near the house. Sounder objections are found in the straying proclivities of the fowl; its disposition to lay away, by which many eggs are lost; and its pugnacious habit of beating other varieties of poultry. But for this latter trick it would long since have been naturalised as a game bird, having been turned into covert with perfect success; but it was soon found that the Guinea Fowls drove away other descriptions of game to such an extent that the birds had to be destroyed on that account, the Pheasants being most valued. As a domestic bird, however, these bad qualities are susceptible of much amelioration, provided the treatment be kind and good. It is almost hopeless to commence a stock with adult birds; directly they are left at liberty they are "off," and probably never return. But by setting eggs under common hens, and rearing them at home, they grow up much tamer, and will flock round the person who feeds them, and even allow themselves to be taken up and petted, like other poultry. When reared thus kindly, and secluded nests are provided, they will generally lay in the house; and if perches are placed high for them, and they are regularly fed every night, will roost at home also. So far domesticated they will pay to rear in places where they can have ample range for their flesh alone, which

is most delicious, resembling that of the Pheasant. The hen lays from sixty to a hundred eggs per annum, the eggs being rather small, very pointed at the end, and of a dark cream colour. These eggs are of beautiful flavour, and there is considerable demand for them in London, where we have often seen them exposed for sale in little baskets lined with green moss.—(From *The Illustrated Book of Poultry* for April.)

THE PROFESSORSHIP OF APICULTURE.

[A CONVERSATION.]

MR. B.—I daresay you are aware, Mr. P, that there is now afloat in the bee-keeping community the idea that we are going to have in England a professor of apiculture. I have come here to-night with the hope that you will let me have your opinions about the matter. I should like to know if you think the country is ripe and ready for a professor, and also if it is possible to find a gentleman ripe and ready for the professorship.

MR. P.—I am aware that there has been some talk about having a professor, but whether the bee-keepers of Great Britain would attach much importance to such an appointment I cannot say. On this point there will be a difference of opinion. If a qualified and suitable gentleman be found and he accepts the office I believe the appointment would be an advantage to the nation, and if an unqualified person get the appointment it will be a misfortune for the nation. Such a person would do more harm than good.

MR. B.—In what ways would a qualified and able man do good as a professor?

MR. P.—His appointment to the office would raise him to the highest platform of teaching and give him a nation to instruct. His utterances would be extensively quoted by the periodical press of the country, and be well read throughout the land. The responsibility of his position would cause him to ponder deeply every phase of apiculture, and cause him to take broad and commanding views of his profession. His language, spoken or written, would be clear and weighty, and his teaching would generally follow and run on the lines of his own experience and seldom in advance of it. A professor of apiculture should be a person of very extensive experience—one who has managed and can manage bees successfully and profitably, and well able to tell others how to do it. As a lecturer he should possess the power of free speech—the power of interesting an audience and commanding attention—the power of leaving his mark behind him as the horse does of his hoof. Such a man would be a light in the world, and a boon to his generation and country if installed as a professor.

MR. B.—Have we such a man amongst us at the present time?

MR. P.—This is the question of questions, often put to myself by myself during the last three months, and I dare not speak confidently on this point. In my humble opinion there is at least one gentleman amongst us qualified for the chair of a professor of apiculture; but as the proposal of having a professor may never be crystallised into shape, or receive the sanction and approval of the authorities, it would be premature and over-officious to name anybody.

MR. B.—Well, but I think the matter should be talked about and well ventilated by advanced bee-keepers, so that the best man may have the post in the event of the authorities deciding to have a professor. I believe with you that harm instead of good would result if an unqualified man were to receive the appointment.

MR. P.—You see, Mr. B, that the first professor would have no precedent and no parallel in this country, and therefore if an unqualified man were to be appointed to the office he would probably be allowed to remain in it for many years. Without ability to teach from his success and experience he would naturally fall back on the statements and guesswork of other adventurers. A professor of apiculture should not live and move in a sphere of speculation, neither should his time be wasted among the knick-knacks of bee-keeping. What is wanted is a man who has made money from bees, and who will show the people how to obtain honey.

MR. B.—Would you pay such a man well, and forbid trading of every kind on his part for profit?

MR. P.—Yes, I would vote for his having a handsome salary, and forbid his trading in hives and bees for profit, for in my opinion such conduct would undignify both himself and office, and tend to make him appear small and impotent for good in the eyes of all around him. For instance, Mr. Ollerhead's lecture on bees had more influence than any other lecture we have had for a long time, simply because it was disinterested and free from oneness.

Now, Mr. B, I have told you all I have to say at present about

a professorship of apiculture. If a competent person can be found who will accept the office I will vote for him, and vote for his being well paid, supported, and encouraged. I would suggest and vote for his having an apiary of twenty or thirty hives kept solely for experiment and comparison, and would vote for his having an assistant to carry out his experiments while he is absent on a lecturing and manipulating tour in the provinces. Those who have the arrangements to make touching a professorship should aim at efficiency and completeness. It were easy to name scores of problems in the natural history of bees that require solution, and as the times bring no second Huber, the professor and his assistant would find work enough at home and abroad in connection with their profession.

That bee-keeping will yet become a source of profit and pleasure to thousands of the rural population of this country I firmly believe, and therefore hope that the proposal of having a professor of apiculture will soon become an actuality in the appointment of a competent man who will stimulate attention and guide bee-keepers in the right direction.—A. PETTIGREW.

OUR LETTER BOX.

Selling Honey (A Honey-eater).—If bee-keepers obtain more honey than they can readily sell locally we presume they would advertise it. We suspect there are many honey-eaters besides yourself who would prefer to purchase "30 lbs. or more" direct from the producers than from grocers and chemists.

METEOROLOGICAL OBSERVATIONS.

THE ROSE SEASON OF 1880—A RETROSPECT.

AS the Rose season may now be said to be over I propose, as I have done in previous years, to give my review of it as far as it has come under my own knowledge. It must be borne in mind by my readers that it is only an individual opinion that I express, and that, although I have many facilities for forming that opinion, yet it may be, and perhaps is, in some particulars altogether wrong. My travels in the cause of the queen of flowers have led me to many places. I have acted as judge on many occasions, have seen many gardens where the Rose is made the object of culture; but instead of going into details (which indeed I have already in many cases done) I shall state in general terms a few things which have struck me.

Although, according to the Yankee notion, you should never prophesy unless you are sure, I did venture to express my belief that, owing to the peculiar character of last winter, we should have a lengthened season, that Roses would bloom irregularly, and hence we should have them for a long time; and so it has proved. The summer blooming has so prolonged itself that there has hardly been a break, and I was continually receiving letters all through August as to the beautiful blooms the writers were gathering; but with even this allowance it cannot be said that it has been a good season, the long dry weather of May and June, and then the deluges of July with its thunderstorms, made it anything but favourable to the Rose. Persons who grow them by thousands can always cut fine blooms. Their maiden plants come to the front, but the ordinary amateur has had to mourn over his best Roses destroyed by rain, and continuous deaths amongst those plants which the winter had seemingly spared. Again has the National Rose Society had to say that their exhibitions, although good, have not been what they ought to have been. Indeed only once during the four years it has existed has there been a favourable season, when the Show was held in St. James's Hall: something exceptional in the weather has marred their hopes. At the Crystal Palace a large number, and at Manchester quite one-half of the entries, failed owing to the unpropitious weather; while in many smaller shows it would have been ridiculous if one did not feel how much disappointment must have been caused to see the poor little things draggled and torn that did duty for Roses. The past winter gave many lessons which will be of value in the future, not the least of them being, I think, that when Roses are hit so hard by frost it is better to prune them down almost to the ground; for in how many instances has it not been seen that

Roses which had seemingly escaped afterwards succumbed? I have seen this very marked in two gardens very widely apart—that of my friend Mr. Tinsley in Cheshire, where I had noticed in May unmistakeable signs of decaying wood, and where I feared complete failure would ensue, but where in July after very hard pruning down to the ground most vigorous and healthy plants bearing grand blooms were everywhere to be seen; the other that of our much-respected Vice-President of the National, Mr. Baker of Reigate, where the plants which had been most closely pruned right down to the very ground had broken out into grand growth, and where the flowers in August were quite equal to those shown in July; so that in one way at least the unpropitious season tended to the enjoyment of the Rose-grower by prolonging the season of enjoyment.

Another very noticeable point was the manner in which old Roses came to the front. While last year there were few Roses and still fewer stands on which we could dwell with satisfaction or cherish their memory, this year there were many which will not easily be forgotten, and especially amongst the older flowers. Was there ever such a triplet of Général Jacqueminot seen as that in Mr. Cranston's stands at the Crystal Palace? And how grandly Beauty of Waltham, Marie Rady, Dr. Andry, Duc de Rohan, Lord Macaulay, Madame Victor Verdier and other dark Roses came out! showing that while here and there amongst the new ones a gem is to be found, older Roses still form the staple from which exhibitors draw their supplies. On looking over my notes and calling to mind the many excellent flowers that I have seen, I would say that the box of thirty-six exhibited by Mr. Jowitt at the Wirral Show was the most nearly perfect stand that I have seen; that the best twelve Roses of any variety were either the Alfred Colomb of Mr. Jowitt at Manchester or the Marie Radys of Mr. Cranston at the Wirral Show; and that the best bloom I saw the whole season was the Alfred K. Williams shown by Mr. Wollaston of Reigate at the Brockham Show—it was simply exquisite, so brilliant in colour and perfect in shape. That we have some good Roses amongst the newer varieties I think will not be denied, but these would require more detailed consideration by-and-by; but the past season may well encourage those who are still dependant on the older varieties for their enjoyment and for the purposes of exhibition.

I think one of the most noteworthy results of the season has been the collapse of the much-vaunted Stapleford Roses for exhibition. I have attended a good many shows, but I think the number of blooms of those Roses might be counted on the fingers of my hands; and I have no hesitation in saying that in every case they made a point against the stand rather than in its favour. In all directions that I have been I made inquiries of those who have proved these Roses and tried them, and in no case did I find that they gave satisfaction. It must be remembered that Mr. Bennett submitted these Roses to no tribunal. The descriptions he gave were his own; and the public, misled by their glowing character, and not a little led astray by the reporters of some of the gardening papers, bought, vulgarly speaking, "a pig in a poke," and they cannot be congratulated on the result of their misplaced confidence. Of this we may feel tolerably certain, that if Mr. Bennett tries to put out another set he will find the reception very different to that with which his first set met. If there are any who have found these Roses different to what I and all those with whom I

have spoken with have, I hope they will make their opinions known. It is no pleasure to have to condemn, and I should be very glad if my judgment were proved to be incorrect; but it was only the other day I was accosted by the head of a very well known London firm, who asked my opinion. When I gave it he said, "It exactly accords with my own; and I am very thankful that I have sold very few of them, for I know what my customers will say."

It is very gratifying to observe the increased love of the Rose. Notwithstanding the terrible discouragements of the last two years, and how largely our National Rose Society is contributing to this good work, each year sees some new exhibitors coming forward, not only amongst the smaller growers, but amongst those who are destined to carry off some of the highest honours that the Rose confers; but it may not be amiss to sound one little note of warning, and that is the possibility of the valuable prizes which are now offered leading exhibitors to be carried away by the desire of obtaining them rather than of what may be to the interests of the Rose and its extended culture. If, for instance, in the matter of dates to be fixed for exhibitions, each grower considers only what is most likely to be the condition of his own Roses and not how it may suit the general mass of exhibitors; or if where classes are made and evidently only intended for smaller growers, a large grower, finding that he is unable successfully to compete in his usual place, enters amongst the classes from which it was intended to exclude him, I am afraid the Society will be shipwrecked. I have never known any Society that can stand against such influences as these. I have known many a successful one come to grief because self-interest came in to destroy like a cankerworm its fair promise, and it is in consequence of this that I would lift up my warning voice. In so doing I have at least one claim to be heard. I am no exhibitor myself, and therefore I have no cause to complain of any injury done to me. I desire only to see the Rose and the Rose Societies now established throughout the kingdoms prospering, although I can well understand how the feelings of an exhibitor may be lacerated. It was a quiet piece of sarcasm uttered by a small exhibitor when he saw himself defeated in one of the smaller classes by a large grower—"I think, sir, we ought to make a class for three blooms to admit Mr. —."

On the whole, then, there is much to encourage Rose-growers. We have not yet seen what a thoroughly good show of the National ought to be; for although that at St. James's Hall was grand, there was no space sufficiently large to show the blooms, and since then we have not had a really good Rose season. Let us hope that a good time may be coming, and that Rose growers and Rose exhibitors may equally with the farmer look forward to next season with brightening hopes and expectations.—D., Deal

DEATH OF MR. ARTHUR VEITCH.

It is with extreme regret, which will be shared by a wide circle of friends in this and other countries, that we have to announce the somewhat sudden death of this estimable gentleman, which occurred at his residence in Chelsea on Saturday last the 25th inst. The deceased became a partner in the great firm of Messrs. James Veitch & Sons on the death of his brother Mr. John Gould Veitch, and he was most assiduous in sharing the conduct of the business under the directions of the active senior partner and present proprietor, Mr. Harry J. Veitch. Mr. Arthur Veitch, during a short and unblemished life, has left a vacancy which will not be easily filled in the district in which he resided. He was not only diligent in business, but laboured with extraordinary zeal in promoting the moral and spiritual welfare of the inhabitants of a populous suburb of the metropolis, his whole spare time having been devoted to the spread of religion among the masses. Visiting the sick, comforting the aged, seeking out those who were in need of aid and consolation, constituted, apart from his business duties, the life work of this truly good and philanthropic man. The amount of good that he has done in this respect none can know; but all who knew him will grant most readily that he was ever willing

to devote himself, at whatever apparent personal inconvenience, to the welfare of others. He was a devoted husband, an affectionate parent, a trusted friend, and a kind employer; and it is not too much to say that thousands will mourn his loss and cherish his memory. He had only been confined to his room about a fortnight when he was called to his reward. He was only thirty-six years of age, and leaves a widow and five children, who will have hosts of sympathisers in their great bereavement. When the majority of our readers peruse these lines the remains of the deceased gentleman will have been deposited in the Brompton Cemetery, the time fixed for the funeral being 10.30 on our day of publication—Thursday morning.

THE GREAT POTATO SHOW.

No one who has not seen one of the International Potato Shows can form a conception of its appearance, and the Show of last week was stated on authority to have been the "finest of the kind that has ever been seen in England." The number of dishes was extraordinary, and the size and appearance of the tubers marvellous; there were whites, and purples, and pinks, and roses, and salmons, and reds; rounds and ovals, and flats and kidneys, all "artistically" disposed on a length of apparently nearly three-quarters of a mile of tabling.

The Show evidenced great activity on the part of the directorate, great enterprise on the part of the nursery and seed trades, great labour and cultural skill on the part of the cultivators and exhibitors, and great competence on the part of those who arranged the collections so orderly and systematically. When a committee can gain friends sufficient to contribute prizes of the aggregate value of £110 in fifty-two classes, while its own share is only £5 5s. in six classes, when new members are charged entrance fees varying from 5s. to 2s., and the Crystal Palace Company probably grants a subsidy to the funds, that organisation ought to be extremely prosperous. The Show appears to be really a gigantic trade affair, and was certainly "billed" well by those who had invested in it, for with the exception of some half a dozen gentlemen the whole of the extra prizes named were given by Potato vendors.

The weight of the produce exhibited could not have been less than 20 tons, and it is a question if there were more than one ton of tubers possessing the requisite high quality for a well-appointed table. The varieties esteemed for their cooking qualities were conspicuous by their absence. There was a thin sprinkling of the Ashtop varieties, perhaps half a dozen dishes of Victorias, and less of York Regents. The round Potato of the Show, a tuber of good appearance and cooking quality, was undoubtedly Schoolmaster, while among kidneys Magnum Bonum was in large force and fine form. The Scotch Champions alluded to in your report perhaps carried off the palm for ugliness, and judging by appearances there is not much wonder that Mr. Luckhurst has discarded the variety, especially as he can ensure an ample supply of Victorias; had he decided otherwise under the circumstances I for one think he would not have exercised sound judgment. Woodstock Kidney was in fine condition, and International Kidney very large, some with other varieties on Messrs. Webbs' stands being of enormous size. Of the new varieties Wormleighton's Kidney was distinct and promising; it is white faintly tinted with rose, and regularly sprinkled with dark dots. It was stated to have been raised by Mr. J. Wormleighton of Guilsborough, Northampton, by crossing the Belgian Kidney with Early Rose. Of the new rounds the Lord Mayor is a large and rather deep-eyed tuber, and not to my mind by any means equal to Mr. Ross's variety Dux—a smart round tuber of the Victoria type. Red Defiance, raised by Mr. Millen, Hamstead Park, Newbury, and staged by Messrs. C. Lee & Son, was very good of its kind. Mr. Bresee, a long red kidney, was splendid, while the red round Vicar of Laleham is popular as an exhibition tuber; and Mr. Fenn's Sulhampstead Kidney, red, and Mr. Lye's Wiltshire Snowflake, flattish round, had many admirers. I cannot, however, particularise every variety of note, and it will be convenient to myself and possibly to your readers to name those varieties in the different sections that were shown in the greatest numbers and best condition. They are as follows:—

White Kidneys.—International, Myatt's Prolific, Jackson's Improved, Woodstock Kidney, Covent Garden Perfection, Yorkshire Hero, Snowflake, Edgcott Seedling, and Pride of America.

Coloured Kidneys.—Mr. Bresee, Trophy, Superior, Red Defiance, Red Ashleaf, Salmon Kidney, Garibaldi, Wonderful, Beauty of Hebron, and American Purple Kidney.

Round Whites.—Schoolmaster, Early Goodrich, Rector of Woodstock, Porter's Excelsior, Davidson's Surprise, Model, White Emperor, and Sim's Early Seedling, and Wiltshire Snowflake.

Round Reds.—Blanchard, Vicar of Laleham, Grampian, Red Emperor, Triumph, and Fenn's Cricket Ball.

Those who desire to "go in" for exhibiting Potatoes may with confidence make a selection from the above varieties, and if they grow them well and stage them without spot and blemish, and of good size, they may hope to have a place in the prize list. I have said of good size, for it was observable that all the best prizes went to Potatoes that were decidedly too large for a gentleman's table; and another thing was noticeable—namely, all the principal prize collections contained varieties the great majority of which will never be of use for culinary purposes. Potatoes of this character largely predominated, and this, I presume, according to the fashion of the day, is termed "improving" the Potato.

A great number of people are asking, "What good is such a Show? What use is it growing Potatoes that will not be eaten?" I heard such questions as these a hundred times, and they elicited few satisfactory answers. It is clear, too, that the Potato shows are no great attraction for the general public. The attendance was disappointingly thin, and only gardeners and "fanciers" appeared to take real interest in the display, and at least half the former could not see the utility of growing Potatoes merely to be looked at. One of them cogently observed that "if there was a Melon show he supposed the prizes would not go to the fruits of the worst quality simply because they looked the best."

The awards were being closely criticised by several competitors, and there was little grumbling. By far the most fault was found with the first-prize collection of twenty-four varieties, not because the tubers were not fine, but because it was alleged there were not twenty-four distinct varieties. Not a few "fanciers" asserted there were only twenty-two really distinct dishes. At one end of the lot was a fine dish of Blanchard, at the other one of White Emperor. The tubers of the latter were decidedly red round the eyes, but not nearly so red as the former, yet it is undeniable that there were many dishes of Grampian in other collections as pale in colour as this dish of White Emperor, while the White Emperors in other portions of the Show were really white and not "red-ended." I pass no opinion on this point, as Potatoes vary much in different soils. All I know is the tubers of the two dishes were identical in form but different in colour; in one they were darkly streaked with red round the eyes, and in the other faintly streaked. The other alleged duplicate dishes were Beauty of Hebron and Early Ohio. On this point one thing is quite clear—namely, there were many dishes of Beauty of Hebron in the Show identical in the form of the tubers, size, colour, and the arrangement of the eyes with the Early Ohio as staged in this collection; and another thing is equally clear—in Messrs. Daniels' collection there was a dish of Early Ohio which was manifestly dissimilar from the dish referred to. The matter, therefore, comes to this—if Mr. Dean's Early Ohio is true, the one sold under that name by Messrs. Daniels is not true, judging at least by the form and colour of the tubers staged in the two collections. I allude to this subject because it was the one topic of discussion when I visited the Show. In some of the classes the Judges had taken a slice off some of the tubers that had a close outward resemblance, and the colour of the flesh generally determined the point at once. It would have been satisfactory had this test been applied to the tubers indicated, for as the matter now stands it is indisputable that some practical "fancy Potato-growers" and successful exhibitors are firm in the conviction that the collection in question did not contain the requisite number of distinct varieties.

Although a great number of people subscribe to the Potato Exhibition, and with the object of improving the Potato as an article of food, others appear to estimate its value by its price per pound or peck. The shows have failed hitherto to bring out any new Potatoes of special excellence for table purposes; but on the contrary, varieties of known high quality are each year represented in less numbers than before; those of imposing appearance, however bad the tubers may be as "cookers," finding most favour with the Judges.

But if failure has resulted in this phase of the subject, success has been achieved in the other object of the Society. A better and more intelligent system of culture has been instituted, which ought to exert a great and widespread influence for good on Potato culture generally. Since the introduction of new and costly fancy varieties much thought has been given to the selection, preparation, and storing of the tubers, also to the management of the soil, planting, and manures. The same care cannot be practised in planting, say, 10 acres of Potatoes in a field as a few rods in a garden, yet the general principles that are found

of value in the former case are to a great extent applicable to the latter, and great good ought to result generally. The prizes offered have encouraged the culture of fancy and show varieties, and a better system of culture has been instituted, so that a gardener can grow a few Potatoes for showing, and by according the same system of culture that is necessary to grow them well to the main crops for cooking purposes, these crops are better than before. Thus nothing is lost in usefulness, the newer varieties being grown in addition to, and not instead of, those best adapted for culinary purposes. Potato shows have therefore done good culturally; yet something more than a mere show seems to be wanted to render the gathering really instructive.

A foreign competitor, Mr. Oscar Mooyer of Angermünde, North Prussia, staged a collection of upwards of forty varieties. The tubers were mostly small and poor in appearance, yet no collection attracted more attention, from the fact that the average percentage of starch each variety contained was stated. This is a step in the right direction, for without some such information, approximative though it be (for it is presumable that the amount of starch varies under varying conditions), it is impossible to form even a vague idea of the culinary value of the newer varieties that are exhibited. If the Directors of the Potato Show could obtain some land for cultural and experimental purposes it is reasonable to suppose they might make it "pay," and at the same time obtain and disseminate valuable information relative to the most important of all root crops.

It is curious to notice in the starch per-centages above referred to that Champion heads the list with 22, a somewhat startling result, while Victoria is only credited with 17 per cent., Peachblow and Magnum Bonum the same. German Reds closely follow the Champion with 21 per cent., and the lowest per-centage of all (ten) is attached to International Kidney, the finest Potato in the Show, but "not fit to eat."

In the shows as at present satisfaction is mixed with disappointment, and something more is needed to meet with anything like the general approval of the Potato-growing public.—A GARDENER.

To all interested in the Potato who had no chance of seeing or taking part in the International Show, your excellent report of it must have been particularly pleasing. If we may judge by the numbers and appearance of the tubers shown, some parts of Wales must be more unfortunate in the disease this season than other parts of the country, as many of the varieties named have been all but lost; but it is well known that only the very pick of the country is shown at such places, and a grand display may not indicate perfection in the crops generally, any more than the exhibits at an international poultry show would prove that all the fowls in the country equalled in quality those shown. Be this as it may, however, there is one thing sure enough—if the International brings out the largest and best-looking tubers to give prizes to, it certainly does not honour eating qualities. This is what many would like to see done; and if liberal prizes were offered for dishes of cooked Potatoes, many varieties which are at present ignored for their small ordinary size and rough coat would come well to the fore. No worse Potatoes could be grown for eating than Beauty of Hebron, Snowflake, Climax, Garibaldi, American Purple, Blanchard, Trophy, Early Vermont, International, Salmon Kidney, Bresee's Prolific, and many others named in the winning collections; while Scotch Champion, Paterson's Victoria, the Dunbar Regent, and others of the true mealy fine-flavoured character are not named. Were a number of prizes given for the best-flavoured Potatoes, it would be an excellent indication to those who wish to grow good-flavoured varieties irrespective of mere size and appearance. Some of those varieties named by me at page 251 would probably not be noticed in a show class of rounds or kidneys, but, as was stated before, they resist the disease, and are excellent when properly cooked. It must not be inferred that I am against Potato shows, but I am sorry to see quality so much in the background.

Besides giving prizes for cooked Potatoes next year, I hope the International Committee will debar people from offering prizes and then competing for them. For any coloured kidney variety Mr. R. Dean, Ealing, offered a first prize of £1, and in that class Mr. R. Dean was first. I was amused to see one of your contemporaries state particularly the donors and winners of the prizes, but curiously omit the donor of this; and no wonder, as it shows a principle seldom found in the true gardener's circle, and one not likely to encourage exhibitors.—J. MUIR, *Margam*.

BLUE HYDRANGEAS.—I have just arrived at the Leenane Hotel Co. Galway, the very centre of Connemara, on the edge of Killary Bay, and with the broad Atlantic in the distance, and among the various items of horticultural interest are the above, which I find

in the Hotel Gardens 4 feet high, and with trusses of flowers 14 inches through. The plants were not protected in winter, while Fuchsias are much commoner used as hedges than Furze, especially on the road to Kylemore Castle.—W. J. M.

GRAPES SHANKING.

I CANNOT accept the theory of Mr. Weir that shanking is caused by a fungus. My opinion so far as my experience goes, which is over thirty years, is that there are three causes that induce Grapes to shank. First, badly made, undrained, and over-rich borders; second, growing the Vines in the early stages of growth in a high and moist temperature, and when signs of colouring take place water is withheld, syringing is abandoned, the floors are not damped, and more air is given to colour the berries; third, injudicious stopping at the period of colouring.

My remedy for shanking is a higher and drier day temperature. Grapes never shank on the open wall. Why? Because they have plenty of air, and, as a rule, a high day temperature, with a corresponding low night temperature. Following out this it will be plain that for Vines to be grown in a vapour bath for nine or ten weeks, and then in a drying room, is contrary to Nature's teaching. By raising the temperature early in the morning, and ventilating by six o'clock, or earlier if practicable, and maintaining a high temperature during the brightest part of the day, with plenty of ventilation at the top of the house and moderate openings of the windows in front, a healthy circulation of air will be insured, which will result in dark green foliage, firm short-jointed wood, highly coloured berries, with very little or no shanking.

The condition of the borders must be considered, and unless they receive proper attention it will be impossible to grow good Grapes. Moderately shallow borders of good loam with a liberal admixture of old mortar rubbish and half-inch bones, good drainage, and a liberal supply of water during the time they are stoning and colouring, with judicious inside management, will be found the best treatment to produce Grapes without shanking.—JOHN GADD, *Thorndon*.

[The Grapes received were excellent both in appearance and quality.—EDS.]

FUNGI A RESULT, NOT A CAUSE OF DISEASE.

THE attempt of "S." (p. 280) to refute my statements by a series of assertions unsupported by a single fact or deduction drawn from his own experience throws no light upon the subject, nor does it shake my position in the slightest degree. Evidently he has not been able to detect the presence of fungus spores, or rather mycelium, before the appearance of plague spots; and my reply to his query is simply that I have never been able to detect it till after the disease has laid hold of the foliage, and I have reason to suppose that the microscope which I have used for nearly twenty years is sufficiently powerful to enable me to do so if it were there. It would be rash to assert that the spores were not present upon the surface of the plant before the appearance of disease, for I am strongly of opinion that they are, and remain quite harmless till the diseased epidermis affords a suitable nidus for their vegetation and growth. Let it not be forgotten that the haulm is invariably free from disease till the legitimate growth of the tubers ceases. I may explain that by legitimate growth the swelling of the young tubers is meant; once checked, this never goes on again. It is true that a second growth often happens, but it is a lateral growth in the haulm and supertuberation in the tubers, which are then spoilt. When the first growth ceases, the work of sap-elaboration in the foliage is finished, and decay may be said to begin, and go on for a time imperceptibly. The gradual drying-up of the tissue of the plant would then appear to render it susceptible to the attacks of a disease which it has hitherto been able to withstand. If at this critical time no rain falls the natural process of decay goes steadily on without disease, and a continuance of dry weather brings the crop to maturity without loss. But if rain falls, what I have termed plague spots soon appear, the spores of the fungus vegetate upon them, the mycelium spreads in and from them on all sides with marvellous rapidity, and nothing we then do can avert the loss of a certain portion of the tubers—often the largest and best.

Regarding Peach blister "S." says, "The only evidence adduced in support of the view that the blister is not the result of a fungus attacking the foliage was the generally admitted fact that it is confined to trees occupying exposed positions. This is all that Mr. Luckhurst now advances, and yet it is by no means sufficient to satisfy an unprejudiced mind that his view is correct." Assuming from this statement that "S." is really open to conviction, I may tell him it is no mere view or opinion, but positive assurance that enables me to say that the blister is caused by cold

wind and nothing else. Plant two Peach trees of the same variety side by side, screen one from the wind, but let it be fully open to the air, and there will be no blister. Let the other tree have no screen, so that the cold north-eastern blasts assail its foliage, and it will be blistered precisely in proportion to its degree of exposure. Observe any branch of this blistered tree that has the advantage of any shelter, and you will see it has escaped untouched. So also if one leaf overlaps and covers another, the under covered leaf is unscathed, while the outer protecting leaf is blistered. Do you require further proof? Unfasten a branch of the sheltered tree and pull it outside the screen, so that the wind may play upon it, and its foliage will be blistered, while that behind the screen, and yet fully open to the air, will remain sound and green. All this I have actually done, not simply with two trees, but with many more of various sorts; and I can point to the vigour and productiveness of sheltered trees that are never checked by blister as affording the best proof that fungi never precedes blister; and I deny the right of "S." to assume that microscopic observation is requisite to decide a matter so simple and so clear.

The existence of an analogy between plants and animals is so fully established, and has obtained recognition from so many of our leading scientific authorities, that it can serve no useful purpose to pursue the subject farther here. Niceties of distinction, or rather difference, may be advanced to support individual opinion in opposition to scientific deductions, but such a mode of argument serves rather to confuse than enlighten.—EDWARD LUCKHURST.

HAMPTON COURT GARDENS.

WITH lawns and pleasure grounds of 65 acres, and a hundred flower beds, the majority of them of great size, there is plenty to see at Hampton Court, and much to admire during a fine season. The grand old Palace, with its historical associations, appears to have a perennial charm. Trains and steamboats are ever passing to and from the metropolis during "the season," while travellers from America and the Antipodes, now so numerous, always appear to make a point of visiting the old Palace on the Thames. The State apartments of the building, the fine parks and magnificent trees, the maze, the wilderness, the Vine, the extensive and excellently kept lawns, and the gay and highly finished flower beds, are a combination of attractions not to be found in any other place of public resort.

It is late to see the flowers now, yet while the freshness of summer is over there is still much to be admired. Save that the Alternantheras have lost much of their brilliancy the carpet beds are yet attractive, and with the aid of canvas coverings will remain so until November. Herbaceous borders have a desolate appearance now, Pelargoniums are nearly flowerless, and Calceolarias, &c., are fast fading, yet the carpet beds are fresh, bright, and greatly admired. Mr. Graham being a skilled draughtsman he has no difficulty in producing fresh designs each season, while he undoubtedly possesses taste to display them effectively. Gaudiness and overcolouring are terms not infrequently applied to carpet beds; but these terms do not apply to the beds here, some of which are chaste almost to a fault by the predominance of neutral colours. It were useless attempting a description of these beds; suffice it to say that of their kind they are excellent, and the designs of some of them and the modes of planting them all can be seen in Mr. Graham's pamphlet. It may be said, however, that the popular Mentha, or Gibraltar Pennyroyal, is doomed as a carpet plant at Hampton Court. It is the only plant that has proved unsatisfactory, and this by having been infested with mealy bug. The stems have been quite white with the pest, a remnant of which is left yet notwithstanding the late drenching rains. The green dwarf plant of the future in these gardens is *Herniaria glabra*. It is deep green in colour, free in growth, requires no clipping or plucking, and is perfectly hardy.

Many of the Pelargonium beds have been very fine, and some of them are even attractive yet, notably those with variegated foliage associated with Violas. No one employs these cheerful hardy flowers in the public parks so freely as Mr. Graham does. The varieties of which he has the largest stock are *V. cornuta splendens*, *The Tory*, *Favourite*, and *Blue King*. They associate equally well with silver or gold variegated Pelargoniums, and impart a variety and a charm to those beds that must be seen to be fully understood. Some large beds planted with *Bijou Pelargoniums*, for instance, mixed with one of these Violas and surrounded with a broad band of *Iresine Lindenii* and a margin of the Golden Chickweed, leaves nothing to be desired. As this is the season for propagating Violas, and as their culture is so easy, requiring little or no glass accommodation, those who desire to add a charm to their gardens should grow these plants, if for no other purpose than for mixing with Pelargoniums of the type indicated.

Some mixed beds of another kind are also extremely ornamental; they are totally devoid of formality, and are free yet rich. They are planted with *Iresine Lindenii* and *Abutilon naevium marmoratum*, and a few plants of *Verbena venosa*. The *Abutilons*, about 2 feet high, have large stately and finely coloured foliage, through which the darker yet free groundwork is seen to great advantage. These beds are much and deservedly admired. Another plant that has given great satisfaction this year is *Cannell's Dwarf Ageratum*, which has formed dense blue lines a foot wide and about 4 inches high. There are only a few dozens of plants grown this year, but there will be thousands planted next year in these gardens.

The coming *Pelargonium* for bedding is *Henry Jacoby*. The few beds that have been seen this year were so striking, that this rich, free, and dwarf variety is being largely propagated for bedding purposes. Mr. Graham has, after taking the tops of the plants, cut up the stems into inch lengths, and is striking them in a little heat, the atmosphere being dry. When this practice is being adopted with a bedding *Pelargonium* now-a-days, when so many are good, it affords sufficient evidence of its value for a particular purpose.

The old kitchen garden attached to the Palace is not open to the public, but Mr. Graham and his friends have ready access. It is in charge of Messrs. Jackson & Son, Kingston, who rent it. About 10 acres are enclosed with lofty walls. These and sundry cross walls are covered with old trees, many of which are bearing good crops. There are 2 or 3 acres of glass—large, lofty, venerable old structures, heavy in appearance, and heated with flues. The Vines are evidently centenarians, and it is surprising to see how admirably they bear under the system adopted by Mr. Latham of constantly cutting out old and training young canes. Some young Vines planted by this excellent cultivator have also made wonderful growth. The Peach house must be one of the oldest extant, and the plan of training the trees is certainly one of the best, probably the very best, for wide and lofty houses. Vertical trellises are formed across the border, reaching from the front of the house to the narrow back path, and from the ground to the roof. These cross trellises are 4 feet apart, and every part covered with bearing wood. By this plan light is admitted to every portion of the back wall, which is also covered with bearing wood from the ground to the roof. By no other plan could so much fruit-bearing surface be exposed so fully to the light, and hence the system is worthy of mention. The crop has been enormous this season, thousands of Peaches having been gathered from the trees. In another house is a small forest of Tomatoes, the trees being planted 2 or 3 feet apart in the border and secured to stakes. A more modern structure is devoted to Cucumbers; it is a low, wide, span-roofed pit, and the crop has been extraordinary. In a division is Vines in pots with hard short-jointed wood—good for either fruiting or planting. Such pits as these, with sunken pathway, and only the roof of glass, are inexpensive and most valuable adjuncts to any garden.

The celebrated old Vine on the other side of the Palace is bearing its usual good crops of useful fruit for the Royal table. There are between twelve and thirteen hundred bunches, averaging about half a pound each. Thus there are a variety of features in this old Palace worthy of notice, and under Mr. Graham's care the enjoyable character of the gardens is admirably sustained.

TOMATO THE CONQUEROR.

IF I have the true variety, as I believe I have, as my seed was from one of the first seed firms in the kingdom, Mr. Iggulden is quite right in his description of Tomato "The Conqueror." I first tried it two years ago against several other varieties, including *Criterion*, *Orangefield*, and *Exeelsior*, and found it earlier, more prolific, equal in size of fruit, and quite as good in flavour as any of the other sorts, and I now grow it exclusively. I have at this time a grand lot growing in a cool house and laden with fruit from bottom to top. They cover a trellis 12 feet high, and with a little help from fire heat will, I doubt not, keep a good supply of fruit till Christmas. All the fruits are more or less corrugated, some of the larger very deeply so, but I do not see that this is any detriment to them.—J. E.

THIS is undoubtedly an excellent variety. It is a good grower, free cropper, early, firm, and of good quality when cooked. It resembles *Vick's Criterion* in colour, being a reddish crimson, but the fruits are generally larger than those of *Criterion*, and not quite so smooth. Some of the medium-sized to small fruits may approach somewhat to the smoothness of an egg, but nine out of ten are slightly corrugated. Mr. Iggulden appears to possess the true variety, at least if the one I have endeavoured to describe is true,

and I have no reason to suppose it is not. Your correspondent "SINGLE-HANDED" may also have the true variety—that is, if he has grown his plants in pots and cropped them heavily. Under these conditions the fruits of all Tomatoes are smoother than those produced by plants in rich soil or lightly cropped in pots, the plants being at the same time generously fed with rich top-dressings of liquid manure.—D.

ZEPHYRANTHES CANDIDA.

A CORRESPONDENT, who sent us specimens from which our engraving was prepared, writes as follows concerning the good

Fig. 58.—*Zephyranthes candida*.

qualities of this charming plant:—"I now have scarcely a more attractive occupant of a border devoted to select hardy plants than the white West Windflower which is planted in moderate-

sized clumps. The flowers being freely produced, Crocus-like in form and pure white, render it especially pleasing at a time of year when the borders are fast losing the gay appearance they bore during the summer. In sheltered nooks upon the rockery this *Zephyranthes* is also very beautiful, and may be advantageously planted with the autumn-flowering *Colchicum*.

"It is of easy cultivation; any well-drained border of rather rich soil near the base of a wall or similar sheltered position suiting it admirably. It increases by the production of offsets or young bulbs, which may be separated from the parent plant and transferred either to pots or borders. Seed is also freely produced, but that mode of increasing our stock is slower than the other. However, as an autumn and late summer-flowering plant this species is very useful, and I recommend it to the attention of all lovers of hardy plants."

THE EFFECTS OF ELECTRICITY ON VEGETATION.

ON witnessing the destructive results of excessive oxygenation which presented themselves in the seeds killed by the positive electrode of the battery, and as also produced in the stems and branches of trees and plants by the contact of rusting iron, it naturally created a desire to learn what would arise from the opposite arrangement of placing the iron in contact with the roots instead of the branches, and thus reversing the order of the metals in the plant case; and no sooner did the thought arise than the necessary steps were at once taken to put it into practice. A small cylinder of sheet iron resting in a zinc pan was first half filled with drainage (this precaution was taken to prevent any possible access of zinc solution reaching the roots, as all zinc salts appear to be injurious), and the remainder with a compost of peat, loam, cocoa fibre, and sand, in which some half-dead Ferns just unpacked from Madeira were planted, but with very little hope of their recovering. They very soon, however, showed signs of life and were not long in being resuscitated, after which they began to grow vigorously, and continued to do so with considerable luxuriance. Reflecting on this arrangement and its results it was directly perceived that the zinc was altogether superfluous, it being of the same electrical condition as the earth, and therefore of no advantage whatever, and it was found to be equally effective without it.

This same principle was then carried out on a more extended scale. Having a small conservatory situate in a confined part of a densely populated city, closely surrounded with high buildings together with a whole forest of smoking chimneys, and consequently within the influence of an atmosphere of the worst possible character, and one almost poisonous to plants, possessing in the highest degree that "want of strength" or the "air not strong enough" which the gardeners say prevents their being able to grow Roses and other plants in the vicinity of large towns, this was deemed a very favourable subject for experiment. The structure is facing the south, but gets the sun only in the middle of the day, and enjoying very little of it for several months in the winter. On the east, south, and west it is shelved with half-inch slate slabs supported by iron brackets neatly japanned (which latter now turns out to have been a mistake). The floor is of Minton's tiles, and there are sufficient hot-water pipes to keep out the frost. Now, with these appliances it was hoped and expected that plants would bear their city quarters with some degree of satisfaction to their owner; but it was not so by any means. Plants "bought in" soon began to deteriorate in their appearance. Flowers became smaller and fewer, the soil turned musty, and mildew became a constant accompaniment. After various trials the following plan was adopted as being the most slightly and successful. A perforated trellis of cast iron, in sections a yard long, 8 inches wide, and half an inch thick (costing 3*d.* per foot run), was fitted to cover the shelves and to serve as the immediate supports for the plants. Standing upon this the plants had their roots directly within the influence of the chemical action pertaining to the oxidation of the metal, and were consequently benefited thereby. The plants very quickly lost their unhealthy appearance and commenced growing freely, and, what is equally important, for the last few years not a trace of mildew has ever made its appearance. A plant of *Polypodium vulgare* var. *Ewingi* standing in an iron wire basket, but insulated from the floor by three wooden legs, and growing in an 8-inch pot, is now 2½ feet through, with fronds above 20 inches long and 6 to 7 inches wide. Many other plants now do equally well, and produce as healthy and almost as luxuriant foliage as can be obtained under ordinary circumstances in better localities. On the entire western side or end of the house a rockwork, formed of furnace clinkers, has been built up from the floor to between 8 and 9 feet high (enclosing the slate shelf), having all the overhanging parts fastened to the

back wall with unprotected iron stays, and this again has been a complete success. The difficulty is rather to keep the occupants within bounds, and from becoming too luxuriant for the size of the house. Even that most fastidious of English Ferns, the *Asplenium marinum*, has made itself quite at home, producing tufts of fronds from a foot to 16 or 17 inches long, whilst seedlings come up profusely in every direction.

Although it may be possible for some minute portion of the iron by becoming dissolved to find its way to the roots, it is not to this we have to attribute the effects described. The stimulus afforded to the plant is derived from the combining of the iron with oxygen. It is a well-known law that metals in their reguline or bright state are insoluble in acids, but not so when they have combined with oxygen; hence it is not the metal direct that is dissolved, but its oxide or rust. In the chemical battery—composed of zinc, copper, or platinised silver, and sulphuric acid—the zinc is first oxydised and then dissolved, and it is this act of combining and being dissolved that furnishes the electricity, the quantity of which is always in a direct ratio with the quantity of zinc consumed. In the same manner electricity is evolved during the process of oxydation of the iron, which electricity then stimulates the roots within its reach to greater activity, forcing them to take in food to a proportionate degree. Now, as all chemical decompositions are attended by the development of electricity, it will be obvious that as all animal or vegetable matter in a decaying state is undergoing a chemical change, consequently mulching the ground with any decaying material in a moist state will necessarily be a far more complex operation than is commonly supposed. In the usual dung hotbed the decomposition is accompanied by heat, as everyone knows, and in Nature it is scarcely possible to have any one force developed without some other force accompanying it.

By the modern doctrine of "the correlation of the physical forces," heat, light, electricity, magnetism, motion, and chemical action are all considered to be equally related to each other—that any of them may be converted into any other, or into all the others reciprocally, each one disappearing as some other or others make their appearance. Thus it may be said, in other words, that there is but one force, and that this force appears under different guises according to the mode of its development. Hence, when speaking of electricity in relation to organic life, it is wholly impossible to dissociate it from its congeners, heat, light, &c. From light as an agent, heat, electricity, and chemical action are prominent effects. From heat we derive motion and light, and chemical action as well as electricity as ordinary everyday commercial results. Were any persons to be asked what they understood by the term "electricity," in all probability the answer would be "thunder and lightning!" Now, this reply is, to a certain extent, both right and wrong. Electricity is the origin, but that which is seen and heard is only the result of the electric discharge. Rub a piece of amber or good red sealing wax briskly for a few seconds on the coat sleeve, and then present it to a few small scraps of thin paper, and these will immediately dart up and adhere to it. It is this attracting force that represents the electricity, just as the attraction of the magnet represents magnetism, whilst the motion of the paper is only the result. But this attracting force has one special feature which distinguishes it from the ordinary attraction of gravitation. After the pieces of paper shall have been in contact for a few seconds they will dart away again, and then cannot be re-attracted by the sealing wax or amber a second time; yet if a piece of glass, which gives out the opposite electricity, be rubbed and presented they will adhere to this as they did originally to the wax or amber, the law being that opposite states attract, but similar states repel each other. In former times it was supposed there were thus two electricities which attracted each other; but the present belief is that there is only one which has undergone polarisation, the same as exhibited in the magnet. Hence it is the attraction of these two oppositely polar states which, recombining suddenly, produce the report and flash of light heard and seen in the tempest. The darting away of the pieces of paper indicates a very important fact, by showing that certain bodies are capable of receiving and retaining an electric charge which regulates their future proceedings. Thus two clouds may become highly charged and expend their explosion harmlessly between themselves; but when the earth and the clouds are opposed, and the discharge occurs from one to the other, there is then danger to all terrestrial occupants.

The earth and the atmosphere are always, when in a normal condition, oppositely electric, and it is between these two conditions, not when they are in this highly explosive humour, but when they are apparently passive and unconcerned, that their influence upon vegetation is most effective. From the battery we obtain electricity, but from the electricity of the earth and air

we obtain chemical action, and it is from this source that vegetation derives its primary impulse; but the manner in which this is effected must be left for the present. It will be necessary first to consider the behaviour of oxygen and carbon, which latter is the main food of the plant, towards each other, as well as their conduct generally under ordinary electric treatment. Burn a small piece of any animal or vegetable substance, and it will be converted into a dark carbonaceous mass. Now this carbon or charcoal is the fundamental material which constitutes the framework of every organic being; and just as the bricks of a building, which, when pulled down, may be used over and over again and built up in any other form or description, so is the carbon indestructible, allowing it to be re-dissolved and wrought up again and again into any other being. Take a piece of charcoal and burn it a second time and all its blackness will disappear, leaving only a small amount of white or grey ash—the earthy part of the original substance. The carbon will have been dissolved in the oxygen of the atmosphere and passed off into the latter as an inodorous and invisible gas, and it is commonly believed that this source furnishes the entire food of all vegetable life. There is reason, however, to consider this to be not strictly the case, as will be seen hereafter.

If the two terminal conductors from a small battery of several pairs of elements be tipped with pieces of platinum wire, and these latter be then dipped into a portion of very dilute sulphuric acid and kept a short distance apart, bubbles of gas will be seen to be given off by each wire. These are the component gases oxygen and nitrogen, which, when combined, constituted the water that has been electrically decomposed. This is termed "electrolysis—a loosening by electricity, and forms the first step in all electro-chemical action. The elements of any compound are first loosened from their original attractions, and then re-assorted according to whatever other elements may be within their reach, and occupying the requisite place in the scale of attractions. Instead of the platinum-tipped electrodes let the copper wires be placed in an acid solution of sulphate of copper (the blue vitriol of commerce), and one—the positive wire, will be seen to dissolve, and at the same time a new fresh coating of bright copper will form upon the other wire—the negative. Now, in nature there is always this dissolving and reproduction going on simultaneously in the growth and renewal of organic forms, and it is this process which has to be encouraged by the application of all extraneous assistance.

Carbon being insoluble in water and not adaptable as food in its solid state, the provision made is, that it can be dissolved by oxygen gas, and in this form is soluble in water. It now enters the plant in this liquid state, combined with other ingredients, and is transferred to all parts, even the minutest, as nutrient sap. Then, in the leaves exposed to the light or sunshine, it is again rendered insoluble by the oxygen being driven off. It used to be a very favourite experiment to enclose a sprig of Rosemary within an inverted jar of water placed in the sunshine, and then to prove that the gas exhaled was pure oxygen. It thus appears that the oxygen derived from the atmosphere serves principally the office of "carrier," or as a vehicle for the transport of carbon into and out of the system—into plants and out of animals. But as both oxygen and hydrogen enter largely into the composition of plants there is every reason to infer that this is wholly derived from the water. The oxygen being attracted by the positive and repelled by the negative, it is thus driven into combination at both ends. By the negative it is recombined with hydrogen, producing damp or moisture (which will be again referred to), or the hydrogen may be combined with carbon, producing the oils and resins, &c.; whilst at the positive the oxygen will be united with carbon, forming carbonic acid. The nitrogen of the atmosphere may be united by either, by one into nitric acid, and by the other into ammonia or any other nitrogenous compounds.—W. K. BRIDGMAN, *Norwich*.

[The Fern fronds accompanying this communication were extremely fine.—EDS.]

PRIMULAS DAMPING OFF.

It will soon be time for our good friends the Chinese Primulas to go off from that dreadful malady termed by different gardeners "canker," "rotting at the neck," or "damping of the collar." To those who may not fully understand the nature of the disease, I may say that it is simply the decay of the tender skin of the stem of the plant just at and above the ground level, and that it is only in the winter it is seen. For my own part I would not know that there was such an affection decimating these beautiful winter flowers, were it not that the annual recurrence of remedies and modes of prevention given in the gardening journals keep the

matter before my mind. The reason why so many fail in keeping these and many other plants in a state of health during the winter months is because they forget, or have never realised, the fact that the plants must be kept growing freely. Our Primulas are grown in a temperature of 50° to 55° throughout the winter. They are freely watered with liquid manure when they require it, and instead of getting unhealthy they require standing wider apart twice during the season. Treated thus we have had plants in February and March, grown in 5-inch pots, measuring 18 inches across. I certainly do not recommend a lower minimum temperature than 45° for these plants during the winter months.—B. T.

HOLIDAY NOTES.

YOUR able correspondent, Mr. G. Abbey, at page 43 publishes a truth that employers would do well to consider—viz., that they advance their own interests when they give their gardeners an opportunity of visiting places of note. Such a holiday freely given is a gift doubly good, for it benefits both they who give and they who receive. However, as I do not intend to draw out these notes to any length I will briefly state what I saw at

GARSTON VINEYARD, LIVERPOOL.

This noted place continues to rank foremost amongst the Vine and Grape-producing nurseries of the United Kingdom. That Mr. Cowan is a master at the cultivation of the Vine in pots is amply demonstrated by the thousands of strong, clean, and healthy Vines 10 to 12 feet high now to be seen in the large house. These, at the time of my visit (August 3rd) were ripening in the most satisfactory manner, canes the thickness of a man's forefinger and of the desirable firmness of character, and all raised from eyes this season! for if I remember aright Mr. Cowan stated that he had not a "cut-back" on the place; indeed the pot Vines alone are well worth a journey of a hundred miles to see. A house 150 feet by 32 feet, span-roofed, formerly occupied by fruiting Vines, chiefly Muscat of Alexandria, is now filled with Vines in pots. The old Muscat house is filled with as good a lot of Grapes as it contained twelve and fourteen years ago, which is saying a great deal; in fact the Vines are as vigorous as ever they were, the causes not being far to seek—viz., judicious cropping, generous feeding, and constant introduction of young wood as the old stems deteriorate. The extension system is being carried out there with very favourable results as regards its application to the Vine. In a small house, which was formerly the early vinery (and which, by the way, is considerably elevated, the pathway and surface of the border being nearly 6 feet above the ground level), is a fine plant of Gros Guillaume, which has produced and finished a crop of 175 bunches averaging 2½ lbs. each, and now covers, including this season's extended growth, a superficial area of 1200 feet. This case is worth the consideration of those who find Gros Guillaume to be a shy bearer when grown on the short-spur and single-rod system. That grand midseason Grape, Madresfield Court, is another good example of extension at Garston, where it nearly fills what were formerly two Peach houses; it has produced this year 270 bunches of good size and quality. I think this Vine was planted ten years ago.

I noticed in one of the plant stoves two good varieties of Croton. *C. Duke of Buccleuch* and *C. interruptum aureum*, each very distinct in character, and will be very valuable for table decoration or exhibition purposes. There is a large number of clean healthy plants suitable for market in the other plant houses and pits, and Mr. Cowan thinks of destroying the Vines in the famous north vinery and filling it with Ferns, a class of plants he requires by the thousand every week in the year.

The notorious lime kiln is still engaged in heating nearly all the glass structures on the place. In spite of all that has been written about it, and judging by what I heard and saw, will continue to do so, as the lime sold nearly clears the cost of all the coal consumed in the Vineyard. In conclusion I may say the fame of Garston Vineyard is in safe keeping whilst it is in the hands of Mr. Cowan.—J. U. S.

THE PALM GARDENS OF ELCHE.—These gardens are far-famed. Although the Dates are inferior to those of Africa and the East, they have a ready sale throughout Spain, where the other products of the tree are also largely utilised. The small leaves, which grow on the top of the tree, are tied for several months, till they blanch and lose all colour; they are then cut and sold, to be dressed with ribbons and blessed, carried in procession upon Palm Sunday, or hung for the rest of the year on the balcony of a house. Other leaves are used in the manufacture of spurious cigarettes; while the timber of the trunk, a firm, hard wood, is in request among the carpenters and handicraftsmen. But the Date fruit is the

chief product, and the annual harvests of them are worth many thousands of pounds. It is amusing to watch the activity and hardihood of the gardeners, who still ascend the tree to pluck the Dates as they did a thousand years ago. A loose rope passed round their waists is tightened by the pressure of their feet against the bark of the tree; their hands are thus left free to help them in their upward climb.—(*Cassell's "Picturesque Europe."*)

IN reference to the illustration of *RUBUS ROSÆFOLIUS* VAR. *CORONARIUS* that appeared in our last issue, we are informed through a paragraph which appeared in last week's *Gardeners' Chronicle*, that the original block was engraved by Mr. W. G. Smith for that paper, in which it first appeared. We obtained the block from the source *which we acknowledged*, and it was inserted precisely in the condition in which we received it. At the time of using it we had forgotten that it had long since appeared in the *Gardeners' Chronicle*, and it is too much to expect of any one that he should remember what illustrations have appeared in that paper, and we doubt if anybody would care to tax his memory to that extent. Yet, if we have done wrong, most readily do we render our acknowledgments to our contemporary. We never mutilate blocks that we, like the *Gardeners' Chronicle*, occasionally borrow, and we invariably acknowledge the courtesy of those who favour us with the use of them; if we fail to do so it is through an oversight. We re-echo every word our contemporary has used in reproaching those practices of which we are too often made the victims. There are other forms of appropriation, or misappropriation rather, of which we have to complain besides the purloining of matter and of illustrations. One of the most flagrant and unfair of these from which we have suffered is at the hands of the *Gardeners' Chronicle* itself. It is no less than the adoption of our title. A few years ago the *Gardeners' Chronicle* thought it advantageous to remodel its title and discarded its old secondary distinction. It called itself "The Gardeners' Chronicle, a weekly illustrated Journal of Horticulture." Of course, a gardeners' chronicle must be a journal of horticulture—even Dundreary could understand that. The effect of this was to cause a confusion between our contemporary and this Journal of which we have repeated instances. We do not say that this subordinate title was adopted for the purpose of sharing the wide popularity which the *Journal of Horticulture* enjoys, as it might have been done with the same inadvertence as that by which we used the *Rubus* illustration; we hope it was so, nevertheless to have avoided ambiguity it would have been better if that subordinate title had not been adopted, but allowed to continue as the rightful property of the *Journal of Horticulture*. "A feeling of what is due to the honour of journalism, as well as to ourselves, has prompted these remarks."

— THE beautiful *CATTLEYA EXONIENSIS* is now flowering in Messrs. Veitch's Nurseries at Chelsea, a small plant having two spikes bearing six gorgeous blooms, with two other spikes showing. This is one of the richest of the genus, and as it is now becoming tolerably plentiful it will soon find its way into many collections in which it is not yet represented, and where it certainly should be to render them complete. *C. Devoniensis* is also flowering, and several small healthy plants of *Lælia præstans* are very attractive.

— A WRITER in the "Science Gossip" for October gives an interesting description of *ANACHARIS ALSINASTRUM*, the Water

Thyme or Canadian Water Weed, introduced to England about forty years ago, since which time it has rapidly spread over the country; and as only pistillate flowers have been observed, this surprising increase was supposed to have been effected solely by division of original plants. The writer referred to states that "having examined the plant carefully in various places during the last two seasons, in the hope of finding either male or perfect flowers, I have at length been rewarded by finding the former growing sparingly in a pond on the Braid Hills, near Edinburgh. This is probably the first record of their occurrence in Britain." Illustrations and dissections of the flowers and plant accompany the remarks.

— WE have had several inquiries concerning *CLEMATIS TUBULOSA*, a pretty species that is by no means so generally known as it deserves to be. A fine specimen is now flowering on one of the old walls at Kew, and the profusion of its bluish lilac-coloured flowers in contrast with the dark green foliage is most agreeable. The species is allied to and closely resembles *Clematis Davidiana*, and they are both natives of China.

— THE CRYPTOGAMIC SOCIETY OF SCOTLAND announce that "a grand Exhibition of FERNS, MOSSES, FUNGI, &c., will be held in the Coal Exchange Hall, 11, West Regent Street, Glasgow, on Thursday September 30th, and the following day. A very extensive collection of plants will be exhibited, comprising specimens of all the British Ferns, many exotic Ferns, including Tree Ferns, Club Mosses, British and foreign Mosses, Seaweeds, Lichens, Liverworts, &c.; fossil Ferns, Horsetails, and many thousands of fresh Fungi. At intervals during the two days popular addresses in illustration of the various sections will be delivered by Col. R. E. S. Harington-Stuart of Torrance, Dr. Stirton, Dr. Buchanan White, and other gentlemen." This is the first Exhibition of the kind ever held in Glasgow, and it ought to be highly interesting and worthy of extensive patronage. Messrs. W. J. Milligan, 180, West Regent Street, and R. Turner, 122, Hospital Street, are the joint Secretaries.

— OUR correspondent "NORTH YORK" writes as follows on *TROPÆOLUM SPECIOSUM*:—"I see from reports in the Journal that this beautiful plant is increasing in favour. When its cultivation is better understood it must become a general favourite. I have to report very favourably of my plant, which is now thoroughly established. It has been in splendid bloom all the summer until the present time. I also am glad to say seed has formed, which I hope will ripen."

— THE death is announced of Mr. CHARLES JOHNSON, who expired on the 21st inst. at his residence in Camberwell at the advanced age of eighty-nine. The deceased gentleman for more than forty-four years held the post of Professor of Botany at Guy's Hospital. He was Editor of Sowerby's "English Botany," author of "Grasses of Great Britain," "British Poisonous Plants," "Ferns of Great Britain," and other valuable contributions to natural history. In early life he took up the study of natural science, being one of the first members of the City Philosophical Society, of which Faraday and other eminent scientists were fellow members. In teaching large classes of natural history he was perhaps the first to introduce that system of practical demonstration with such marked success, in place of the dry formal lectures previously in vogue. He was a high authority on agriculture and all subjects connected with economic botany.

— WE have received information of the following GARDENING APPOINTMENTS—Mr. J. Beddar, late at Beechwood, Tunbridge Wells, has succeeded Mr. Elworthy as gardener to Lord Leigh, Staveley Abbey, Kenilworth. Mr. C. Davies, late of Woodcote, Newport Salop, has succeeded Mr. Sandford as gardener to C. N. P. Phipps, Esq., Chalcote, Westbury, Wilts.

— "R. S." WRITES—"I have in my garden a number of plants of *OXALIS BOWIEI*, and they still continue producing their bright rosy crimson flowers in profusion. So charming a plant deserves to be more frequently seen in gardens than it is at present, for not only is it attractive but useful for cutting purposes, though the flowers do not last quite so long as might be desirable."

— WE cite the following relative to the FRUIT CROPS OF CANADA AND THE UNITED STATES from a daily contemporary :—Peaches grow in such profusion that they are regularly given to the pigs. So with Apples. In some of the States in the month of September the leaves of the Apple trees can hardly be seen for the glorious red-cheeked fruit. The farmers in the fruit-growing regions of Ontario, Canada, have not time at the present moment to look after an abundant Apple crop. As a consequence hundreds of tons of Apples become either food for hogs or manure for the ground. "Just imagine," writes a correspondent in the land of plenty, "millions of bushels of magnificent Apples rotting on the ground for want of some enterprising buyer, who might make a fortune by hand-picking them and shipping them to England." In view of these facts, it is tantalising to remember that if we in this country want any decent Apples to eat we must pay from 3d. to 6d. per pound for them; and for Peaches, when they are to be had at all, certainly not less than 2d. each. It is matter for wonder that the "enterprising buyer" does not come forward. He would benefit both himself and the British public in no small degree.

— THE second part of Messrs. Cassell's re-issue of "PAXTON'S FLOWER GARDEN" contains coloured plates of *Dendrobium superbiens*, which does not do justice to that beautiful Orchid, and *Rhododendron cinnamomeum* var. *Cunninghami*, fairly executed. The accompanying letterpress containing descriptions and cultural directions is clear and exact.

— THE BRISTOL CHRYSANTHEMUM SOCIETY will hold their annual Exhibition on Wednesday and Thursday, November the 17th and 18th. Prizes will be offered for specimen plants and cut flowers, both of large-flowered and Pompon varieties.

— MR. CRUMP, The Gardens, Blenheim, Woodstock, informs us that he has disposed of the entire stock of the new Melon "BLENHEIM ORANGE,"—which was awarded a first-class certificate, as well as the first prize of the Royal Horticultural Society—to Messrs. James Carter & Co., High Holborn, London.

— MR. W. ROBERTS informs us that many people are making a considerable amount of money of MUSHROOMS IN CORNWALL. Many tons have from time to time during these past few months been sent from the Penzance station, besides great quantities from other stations in Cornwall. Blackberries are also sent away in large quantities, both these and Mushrooms realising good prices.

— REFERRING to the heavy cropping qualities of the MAGNUM BONUM POTATO, Mr. A. Fowler, Cams Hall Gardens, Fareham, Hants, states that he obtained a supply of seed tubers from Messrs. Sutton & Sons, the yield from which equalled 36 bushels from 1 bushel of seed. Sufficient has been said at present to indicate the productiveness of the Magnum Bonum.

— WE extract the following from the *Prairie Farmer* relative to EARLY PEACHES IN AMERICA :—"Amsden's June and Alexander began to ripen about the 20th June in Missouri, and the Beatrice and Louise were but a few days behind them. Rivers' Early came a little later, while Kelly's Early was still later. In the Peach region of Delaware and Maryland we notice that the Amsden and Alexander fully maintained their past record. They were larger than either the Beatrice or Louise, and a week earlier in ripening. The Early Rivers ripened just before Early Hales. These five are

the most popular sorts in the East. A number of Peach-growers and horticulturists hold that Amsden and Alexander are identical. The Wilder ripens after Alexander, and is of the same colour. The Gov. Garland—a large firm clingstone Peach—is claimed to be earlier than Alexander. If any of our readers have fruited it this season we should be glad to have a report of its behaviour."

— THE *Irish Farmers' Gazette* published the following under the heading of A POTATO MONSTROSITY.—"Mr. Alfred H. Sheridan has sent us a specimen of a Potato presenting the appearance of a dried and shrivelled kidney-shaped *sac*, with the upper surface rent and nearly altogether displaced, and revealing in the interior quite a colony of young Potatoes, some larger and some smaller than marbles, the whole presenting a curious and singular aspect. This internally prolific Potato, we may remark here, is not of the current, but a previous year's growth. The explanation of the phenomenon is this—Immediately beneath the skin or rind of a Potato is a system of vascular tissue, from which proceed the vessels that feed the external buds or eyes, which, under normal circumstances, are directed outwards. In the present and similar instances, either by reason of the eye growths being persistently removed or from other causes—their development externally prevented—Nature would not be frustrated, and modified buds, resulting in a progeny of small tubers, take the place of the absorbed tissue. We subjoin the note which Mr. Sheridan sent along with the phenomenal tuber :—'This Potato was found in a bag of old Potatoes which had been lying in the outhouse of a small farmer named James Byrne of Rossminna, Westport, Co. Mayo. When first discovered the present appearance was only developing. The tuber was then placed on a dresser for four or five weeks, and continued to grow to its present state.'"

— MR. H. CANNELL, Swanley, Kent, has sent us some very fine flowers of the handsome PYRETHRUM ULIGINOSUM, which is at this time of year so attractive in borders of hardy plants. The ray florets of the capitula are long and pure white, and the whole flower head very neatly formed. The plant is variable in height, sometimes reaching 5 or 6 feet, and at others not exceeding 4 feet, but the freedom with which the flower heads are produced render it very useful for cutting from August until October.

— OUR correspondent, "W. J. M., *Clonmel*," writes as follows respecting THE POTATO CROP IN IRELAND—"As already stated, I have recently been through much of the three southern provinces, and within the last few days had communications from those likely to be well informed in the four, and all agree that the Potato crop is good. Even varieties that failed other years, such as Scotch Down—very largely grown in Ireland—Dalnahoys and Early Oxfords, and perhaps I may add Red Rocks, are all a fair crop; while Flounders, now nearly all consumed, though having a large fraction black, were very large, as I noticed at the time in your columns, as much as 2 lbs. a single specimen. I am sorry to say Early Rose, Snowflake, and Fortyfold were heavily blighted two months since with me, and have kept very badly since. Ashleaf Kidneys have kept better. Those who have Magnum Bonum here speak highly of it. Mr. Luckhurst and your other correspondents who have doubted Scotch Champions will, I am sure, be glad to hear that in Ireland the general description from all sources to me is 'they fill the ground and are excellent food.'"

LIFTING AND POTTING WINTER-FLOWERING PLANTS.

IT may seem a very small matter to lift a few plants out of the open ground, plant them in pots, and arrange them in their winter quarters. Still, it is just one of those operations where if success may be very easy, failure either comparative or total is at least

equally likely to follow, and failure with plants intended for winter or spring use is no light matter. The plants we shall be lifting at the time these notes appear will be mainly Cyclamens, Eupatoriums, Bouvardias, Begonias for winter flowering, Callas, Chrysanthemums, berried Solanums, Souvenir de la Malmaison Carnations, and a few others. These will mostly have had their roots half loosened from the soil ten days or a fortnight previously, in order that the check at the time of removal may be as slight as possible.

There are two ways of treating the plants after being potted—the one to place them under glass without delay, and to keep them close for a time, and also moist by frequent syringings; the other is to let the plants after potting remain in a suitable position in the open air for ten days or so until the roots have taken hold of the fresh soil, and until the approach of autumn frost. I dislike the first plan, for the simple reason that it causes much unnecessary attention, whilst the results are equally good—not a leaf need be lost in either case. But stand the best-prepared plants immediately after they have been potted from the open ground in any dry airy structures, and no wonder if there be a turning yellow of foliage and general debility in all the stock. A month later when the midday sun, which is often hot well into October, has lost most of its power, plants from flower beds for stock purposes can be immediately placed in any kind of structure without any grievous harm resulting, provided enough heat is allowed to give the roots a start.

Two matters of some importance just now is to give a greater amount of drainage to plants that are being potted, and to make the compost sandier than is the case for those having the summer before them.—R. P. B.

JUDGES AND JUDGING.

"A VETERAN'S" remarks on page 275 are well timed. The judging at exhibitions should, as far as possible, be above suspicion or complaint in any way, and it is exceedingly desirable that the judges should be changed occasionally at least; but there are not a few notable horticultural shows where the same men have been employed for nigh upon a score of years. The fact need only be mentioned, and I can tell you what the usual practice is of some of those old stagers who "seek for work," and kill two dogs with one stone. They invite themselves, if the show be in the provinces, to some gentleman's gardener's house in the neighbourhood a day or two before the show to take "a few notes" for some paper, and are lodged and fed, and perhaps driven over to the show when the time arrives, the host usually being an exhibitor himself, and his produce perhaps judged by his guest. After the show our judge invites himself for a day or two to some other places near, where exhibits come from also, to take a few more "notes," and so on from year to year. I could give you the names of both judges and places where this has been done in the most regular way for years, but "he who runs may read."—A.

PORTRAITS OF NEW AND NOTABLE PLANTS.

CRINUM KIRKII.—"This is a very fine new Crinum of the ornatum group, of which the bulb was sent home about two years ago by Dr. Kirke from Zanzibar. It flowered for the first time at Kew in the autumn of 1879. Its nearest ally is C. Forbesianum, from Delagoa Bay, which was lost for a long time, but which we have again lately received and flowered. The present plant has flowers as large and as brightly coloured as the finest forms of C. ornatum, but may be recognised at a glance by its short very stout peduncle, and very large acuminate leaves, with a distinctly ciliated edge."—(*Bot. Mag.*, t. 6512.)

CITRUS TRIFOLIATA.—"This singular and free-flowering shrub is much less known than it deserves to be, it being, in fact, almost unknown in English gardens, though perfectly hardy, free-flowering, and sweet-scented. It has stood unprotected in the open border of the arboretum of Kew for several years, and hitherto has been quite uninjured, even the tender young shoots resisting the early frosts and long-protracted cold of the last two inclement seasons; a fact the more singular when it is considered that the whole plant is evergreen in respect of leaves, branches, and spines, though the leaves are deciduous. C. trifoliata is a native of Japan, where it is much cultivated both as a garden plant and for fences. Its fruit, which resembles a small Orange, is described as very bitter, and having laxative properties. As an early-flowering and sweet-scented hardy shrub this Citrus is likely to prove a favourite, and should it be eventually unable to withstand a winter of unusual severity in the open border, it may still be safe on a wall with or without protection. The flowers appeared in the middle of May of this very backward year, but no fruit has been formed;

the leaves were not fully developed till the end of June. It need hardly be stated that the five-petalled variety is much more attractive than the four-petalled."—(*Ibid.*, t. 6513.)

GENTIANA ORNATA.—"This beautiful little Gentian is a native of the rich alpine meadows of the Himalaya, where it represents the G. frigida of the Hungarian Alps, and from which it differs in the cartilaginous margins of the leaves, and the absence of the filamentous remains of old stems on the summit of the rootstock, as also in the colour of the corolla, which is of an intense blue, not white, like the European species. The G. ornata is confined to the central and eastern Himalaya; it was discovered by Wallich's collectors in Central Nepal, and I have gathered it abundantly in Sikkim at elevations of 13,000 to 16,000 feet."—(*Ibid.*, t. 6514.)

HELICHRYSUM FRIGIDUM.—"A very remarkable and scarce little alpine plant, hitherto found nowhere but in the mountains of Corsica, at elevations reaching to 6000 feet. It was long supposed to be also a native of Syria, it being described and figured by the Syrian traveller Labillardiere under the name of Xeranthemum frigidum, as being found by him on Mount Lebanon as well as in Corsica, and there is in the Kew herbarium a specimen of it from Labillardiere's own herbarium, communicated by the late Mr. Webb, who obtained the herbarium by purchase, and left it by will to Florence, but it is not stated whether it is from Corsica or Lebanon; as, however, it is identical with specimens from the first named country, it may be assumed to be a copatriot. Boissier, in his 'Flora Orientalis' (vol. iii., p. 239), states under H. Billardieri (a Lebanon species and very different from H. frigidum) that H. frigidum is erroneously ascribed to the Lebanon, and this is the general and, no doubt, correct opinion."—(*Ibid.*, t. 6515.)

LACÆNA SPECTABILIS.—Native of Mexico. Flowers very pale pink. "A very little-known genus, of which only two species have been discovered, the present and L. bicolor, on which the genus was founded by Lindley ('Bot. Reg.', 1844, t. 50), and which is a native of Guatemala. The present is very much the handsomer species of the two, and is remarkable for the delicate colouring of the perianth, which in L. bicolor is of a greenish-yellow hue, and not speckled in the lip. The two species differ widely, this having a much longer claw, a horn, concave in front, between the lateral lobes, and a stipitate mid-lobe; whilst that of L. bicolor has a very short claw, a beard between the lateral lobes, and an almost sessile mid-lobe. Lindley, who named the genus, called it by one of the names of Helen (Lacæna), because of its beauty; a compliment which the 'Botanical Register's' representative of L. bicolor does not at all merit; he adds, however, that it may also be derived from *lakis*, a cleft, in allusion to the divisions of the lip. L. spectabilis flowered at Kew in the spring of this year; the Royal Gardens are indebted to Dr. Wendland, of the Royal Gardens of Herrnhäusen, Hanover, for the plant."—(*Ibid.*, t. 6516.)

GLOBE ARTICHOKE FROM SEED.

JUDGING from what I have seen and heard, the last two winters proved unusually destructive among the plantations of Globe Artichokes. This was especially the case last winter, when the growth, the result of a wet dull season, was over-luxuriant, and as a matter of course was very liable to injury from the extra severe frost experienced. Many who succeeded during the previous winter in saving a sufficiency of old stumps to give the required number of suckers for the formation of new plantations, failed completely with them last winter, and that, too, after taking precisely the same precautions in the way of protecting. As a consequence some purchased a fresh stock of plants, and still more, I am informed by a good authority, bought seed and raised their own plants. This in both instances was right enough to a certain extent, but unfortunately neither could be relied on; in the first instance simply because nurserymen were no more able to preserve their stock of plants than were gardeners, and even if they were, but few I imagine would have a quantity sufficient to meet the unusually heavy demand. The way out of the difficulty—and nothing could be easier—was to raise a number of plants from seed, and unless I am much mistaken these same seedlings have proved somewhat surprising to the buyers, as they have doubtless comprised several very startling novelties, of which, unfortunately, fully 90 per cent. were of little value.

Those who have raised their stock from seed, unless much more fortunate than I have been, both during this and previous seasons, possess a great and undesirable variety of Artichokes. Some of which are little better than Cardoons, others with heads of great size but with thin uneatable scales; some with long and sharp spines, and others perfectly spineless; some with flattish heads with recurved scales, and others again, close and perfectly conical—

headed, the colours of some being green, some purple, and others a mixture of the two, in fact no two being exactly alike. All could be obtained from a single packet of seed, in my case presumably of the Green Globe. I have on previous occasions sown seeds of both the purple and green forms, but this season I confined myself to the latter, knowing from experience that I should have more than enough of variety from one packet.

I am not writing this to the prejudice of the nurserymen or seedsmen who may have distributed either seedling plants or seed with the above results, as I firmly believe they are quite unaware of the mixed character of the stock. My motive for again calling

attention to it is simply to elicit the experience of others, as should this be in accordance with mine it may, and I trust will do so, ultimately result in the seedsmen being more particular in their transactions with the continental seed-growers, who, in all probability, grow for seed purposes the purple and green varieties and also Cardoons in close proximity. If I could rely upon seedlings coming true to name I should grow them exclusively, as the heads of those few that are really good are much superior to any I can obtain from the ordinary stock of plants raised from suckers, although given precisely the same necessarily liberal treatment. So convinced am I of the superiority of the produce of the seed-

Fig. 59.—*PELARGONIUM TETRAGONUM*.

lings when true over those of plants obtained by division, that next season I hope to be able to save some seed under glass. This proceeding, however, I cannot help thinking unnecessary, provided proper precautions were taken by the seed-growers, and which ought to be forcibly pointed out to them by our wholesale seedsmen.—W. IGGULDEN.

PELARGONIUM TETRAGONUM.

THIS is one of the most distinct and curious of all the species. With stems of rush-like appearance, the leaves are generally so reduced as to appear absent, but according to the conditions of growth they may or may not develop. They are present on luxuriant or young specimens, and then are as we have shown

them in our illustration. The flowers are of peculiar form, but also showy from their size and delicate pink colour, with dark and conspicuous veining. It was introduced more than a hundred years ago, and forms the subject of a very early plate in the "Botanical Magazine." I have known it many years, but always as a variety, and have, therefore, been delighted to find large plants in the Cambridge Botanic Garden, where the drawing was made. In Haworth's time there were two varieties in cultivation which I have never seen, the one with variegated stems, the other with variegated leaves.—L.

THE COLOUR OF FLOWERS.—At a recent meeting of the Vaudois Society of Natural Sciences, Professor Schnetzler read an interesting paper on the colour of flowers. It has been generally

supposed that the various colours observed in plants were due to so many different matters, each colour being a different chemical combination without relation to the others. Now Professor Schnetzler shows by experiments that when the colour of a flower has been isolated by putting it in spirits of wine, one may, by adding an acid or alkaline substance, obtain all the colours which plants present. Flowers of Pæony, *e.g.*, give, when placed in alcohol, a red-violet liquid. If some salt of sorrel be added the liquid becomes pure red; while soda changes it, according to the quantity, into violet, blue, or green. In this latter case the green liquid appears red by transmitted light, just as does chlorophyll (the green colouring matter of leaves). The sepals of Pæony, which are green with a red border, become wholly red when put in salt of sorrel. These changes of colour, which can be had at will, may quite well be produced in the plant by the same causes, for in all plants there are always acid or alkaline matters. Further, it is certain that the transformation from green into red, observed in the leaves of many plants in autumn, is due to the action of tannin which they contain with chlorophyll. Thus, without wishing to affirm it absolutely, Professor Schnetzler supposes, *à priori*, that there is in plants only one colouring matter—chlorophyll—which, being modified by certain agents, furnishes all the tints which flowers and leaves present. As to white flowers, it has been found that their colouration is due to air contained in the cells of the petals. On placing the latter under the receiver of an air-pump, they are seen to lose their colour and become transparent as the air escapes from them.—(*The Times*.)

THE SEASON AND THE POTATOES.

ALTHOUGH the summer of 1880 has not, perhaps, been without the average number of failures, there are a few remarkable successes which deserve to be recorded for future encouragement, some of which are owing to natural causes, others to dogged perseverance, and others, again, to the two causes combined, as they ever should be.

The enormous crops of vegetables of all kinds, so far as they exceed the general average, are due to a combination of natural causes, which as far as I am concerned are but very imperfectly understood. I can understand that a dry hot spring, which so many people complained of before May was out, was just what was wanted to warm and sweeten the soil after eighteen months of winter; and that the month of June, made up of alternate sunshine and shower, was about the best thing which could possibly follow a hot dry May; but that a wet and comparatively cool July, with the temperature only once up to 80°, should have suited vegetation so well even on the heaviest of soils after a dripping June, is beyond my comprehension. I had no means of measuring the amount of rainfall, but it must have been something enormous. A more than usual quantity would doubtless be absorbed and evaporated by the extra-luxuriant vegetation, for Peas grew 13 feet high, and Cauliflowers turned in a month or six weeks before their customary seasons. Potatoes also and many other vegetables made more than their average growth, and would consequently take up a corresponding amount of moisture; but there still remains a great deal I cannot account for. However, "All's well that ends well," but there is no harm in inquiring into Nature's mysteries, utilise her teachings as much as possible, and then bravely acknowledge how little we know.

I have no doubt that we are indebted to the dry April and May for our comparative immunity from the Potato disease. If, as experiments have gone a good way to show, the resting spores of the *Peronospora* require a certain amount of water to excite them to active vitality, that water was not forthcoming this season at the usual time, and it may be, as our subsequent experience would seem to indicate, that only a very small portion of the spores vegetated successfully. Query, What becomes of the remainder? Have they perished, or are they waiting safely for a more favourable opportunity next year? Certain it is that the disease in the earlier part of the season was very much milder than usual; and it was only, I think, when a successional family of active spores was produced and distributed from the growing Potato tops that the disease increased to any alarming extent; and indeed with the precautions I took I have not had it in a virulent form except upon two small patches, which can be easily accounted for, although in the adjoining village the loss is very considerable.

Some time ago I mentioned that I had all the tops carefully pulled off Myatt's Ashleaf with the exception of a small patch as soon as the first speck of disease was seen in the garden. The patch on which the stems were left was a portion at one corner of a square piece, not selected in any way, but just where the men happened to be finishing, and in all respects exactly like the rest of the piece as far as could be seen. The whole piece was lifted

during last month, with the result that 38 bushels of sound table Potatoes were picked off the portion where the stalks were pulled off with less than half a peck of diseased tubers, while from the portion where the stalks were left on were dug about a bushel of apparently sound tubers and quite as many bad ones as came off all the rest of the piece; besides, there were a great many rotted so badly that only traces of them could be found. The best tubers from the badly infected portion were used at once, it being thought undesirable to allow them to come in contact with those which had almost had a clean bill of health. We are using the Potatoes now from the main piece of ground, and find them good in quality and free from disease.

I learned from the badly infected portion one thing worth mentioning. I was willing to admit before this experiment that by pulling off the haulm we invariably sacrificed size of tuber to some extent, but at digging time I found it was not so in this case, as those which were left sound on the badly infected piece were no larger than those from which the stalks had been removed. This proves to my mind that in this instance, when the disease had a firm hold, which was not many days after the tops were pulled from the other portion, no appreciable growth of tuber took place to compensate for the loss in number.

A select stock of the old Ashleaf was taken up and stored early in July before the disease had affected it, and has kept perfectly sound. A portion of another patch not carefully selected, and which was only planted for early kitchen supply, was left in the ground without removing the tops, and I do not think there are any sound Potatoes left at the roots of these at all. Now it is plain that with early Potatoes we can generally evade the disease in two ways—first, by pulling the haulm before the disease has secured any hold; and secondly by lifting the whole crop while the tops are still green. Either plan will answer, and each has its advocates; but as I never have more hands than I know what to do with, I prefer pulling the tops so as to make the crop safe, which is not a long job, and digging when a favourable opportunity occurs. I never remember tasting the old Ashleaf so good in quality as it was early this year; its season, however, was soon over, and it was not good after midsummer. The crop was very large, and it is still in my estimation the best very early Potato in existence.

The tops of Magnum Bonum are now gone, and we are waiting for favourable weather to lift the tubers, of which there is a large crop. Scotch Champion is still (September 16th) growing vigorously. Although many of the side leaves are gone, the tops are green and the stems unharmed. It is already of good quality when cooked, and will be a great boon to the labouring class about here, who have been induced to try it this season rather largely, and with excellent results. I anticipate that more of it will be planted in this neighbourhood next year than of all other late kinds. It is a very rank grower and a very ugly tuber; but "The proof of the pudding is in the eating," and tried by this standard, as well as by the abundance of crop, its qualities are second to none, and while its constitution remains as strong as it now is it is the poor man's Potato *par excellence*. It wants such careful cooking as it is not likely to have at the hands of many besides poor men's wives and daughters, and therefore is not likely to become popular with those who keep professed cooks of the modern type.

I intended in these notes to embrace a variety of subjects, but the "noble tuber" has taken up all my time and space and the others must wait.—WM. TAYLOR.

REVIEW OF BOOK.

A New and Easy Method of Studying British Wild Flowers by Natural Analysis. By FREDERICK A. MESSER. London: David Bogue.

ORIGINALITY of a marked and advantageous character is comparatively rare in the now numerous works devoted to elementary botany. The majority are but slight variations of one common plan, and their relative merits may be gauged more by the accuracy of the instruction given than by an improvement on other works. The book now under notice is, however, a remarkable exception to the general rule, and with this distinctness it also possesses advantages of considerable value. The following explanation of the author's design appears in the introduction, and will convey a correct idea of the character:—

"This work has grown out of a want, which was much felt by the author, of some method which would simplify the study of our native plants, by placing before the student the characteristic distinctions of their natural orders and genera in a clearer and more striking manner than is possible by means of verbal description alone, and which would at the same time possess in itself the principles and advantages of analytical arrangement.

"In botanical letterpress description the recurrence of numerous technical terms unaided by illustrations is always a difficulty, and frequently a source of discouragement to beginners; the usual method of acquiring a knowledge of these terms being very laborious, and the consequence is that the attempt to master it is often abandoned.

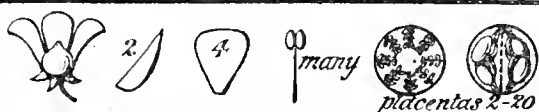

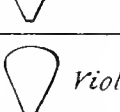

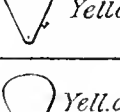

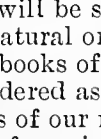

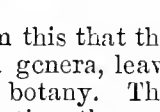

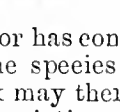

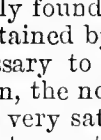

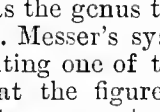

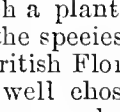

"And even when the description is accompanied by full illustrations of the individual plant there is the danger of undue attention being devoted to the latter to the neglect of the descriptions of the ordinal and generic features. The student is too often satisfied if he can apparently identify his specimens by a general resemblance to the illustrations, even though he may gain little or no knowledge of the reasons for their classification.

"With a view to obviate these objections and to supply the want referred to, the author has adopted a new method of utilising illustrative figures. These figures represent the separate parts or dissections characteristic of the orders and genera, and are disposed in harmony with verbal analytical arrangement; they form, in fact, a series of illustrated analytical tables, the application of this principle to the figures and the combination of verbal and pictorial analysis being the special features of this work.

"That illustrations are a more powerful as well as a more alluring and ready means of imparting knowledge than letterpress alone will

not be doubted. As the eye travels rapidly over the illustrated page it takes in at one view the contents, and there is presented to the mind a comprehensive idea of the subject. So with regard to this work; a few references to an illustrated analytical table will go far to familiarise the mind with the relationship which exists between the various parts of the plants, and the impression produced will soon deepen and become fixed on the memory. This pictorial method resembles more closely than any other the natural process, or that which is intuitively followed in the comparative examination of the parts of the plants themselves."

The first portion of the work is devoted to the delineation of the great divisions of the vegetable kingdom, the Exogens, Endogens, and Aerogens; then follow the illustrated characters of the natural orders, and then the genera arranged under their respective orders. The symbolical figures and dissections are placed on the left hand page, the one facing it containing the verbal description corresponding to the illustrations. As an example of this we give the accompanying engraving, representing the Poppy order, which indicates the method employed better than mere description could do.

4. PAPAVERACEÆ. 			
		 Red or white	1. PAPÁVER. 
		 Yellow	2. MECONÓPSIS.
		 Violet	3. ROEMÉRIA..
		 Yellow	4. CHELIDÓNÍUM.
		 Yellow or red	5. GLAÚCIUM.

4. POPPY FAMILY. { Corolla regular, polypetalous, inferior. Sepals 2. Petals 4. Stamens many. Capsule 1 or 2-celled; placentas 2 to 20, many-seeded.

Capsule 1-celled; placentas 4 to 20 (forming imperfect cells).

Capsule globular or oblong. Petals red or white

1. Poppy.

Capsule obovate. Petals yellow ..

2. Welsh Poppy.

Capsule 1-celled; placentas 2.

Capsule linear, bristle-pointed. Petals violet.....

3. Roemeria.

Capsule linear, smooth-pointed. Petals yellow

4. Celandine.

Capsule 2-celled; placentas 2.

Capsule very long, curved. Petals yellow or red

5. Horned Poppy

It will be seen from this that the author has confined himself to the natural order and genera, leaving the species to the ordinary handbooks of British botany. The work may therefore chiefly be considered as representing the general variations and prevailing forms of our native plants without being a guide to the determination of species; but as the genus to which a plant belongs can be readily found on Mr. Messer's system, the species could soon be ascertained by consulting one of the "British Floras." It is only necessary to add that the figures are well chosen and clearly drawn, the nomenclature correct, and the general execution of the work very satisfactory. It will undoubtedly prove of great assistance to youthful students of botany, and to such we cordially recommend it.

SAXIFRAGA MUSCOIDES VAR. RUBRA.

THIS pretty little Saxifrage ought to be in every garden. Those who saw it at the Manchester Whitsuntide Exhibition in Mr. Brownhill's of Sale, Manchester, collection of herbaceous and alpine plants will not soon forget it. With me it has been flowering since about Easter in the open garden, and during the dry weather in spring and early summer it were one mass of bloom. In August of 1879 I had two plants which I divided into forty-two plants, which were very small, but in spring of the present year they were about 6 inches across, beautiful green circular patches—yes, green; almost when every other thing in my garden were brown or almost dead. It would make a beautiful edging either separately or planted alternately with Daisies, Aubrietias, or similar dwarf plants. It ought to be divided annually, which adds considerably to its well-doing.—JAMES PERCIVAL.

A QUEENSLAND FLOWER GARDEN.

POETS have sung of the flowers of eastern realms, and artists have pictured the floral wonders and delights of sunny lands, but for ability to produce in perfection a diversity of such beauties of Nature Queensland cannot be surpassed, even if equalled. Climate, soil, situation, and skill in cultivation are all requisite, and are all to be found there. It may be admitted that there are places more

favoured than Australia with native floral charms, though these are acknowledged to be considerable, and the north-eastern colony has more than its relative share of the vegetable fair ones. But without dwelling upon the denizens of the forest, or describing the blossoms which so profusely adorn the valley and hill, let us turn to the story of a flower garden as described in the "Queensland Calendar." The duties of the florist are those laid down each month.

In January, the height of summer, he has to regulate the growth of climbers, examine Dahlias, stake and tie plants, weed beds of Verbenas, Petunias, and Pelargoniums, sow annuals for autumn, propagate Carnations, bud and train Roses, shade and water plants in pots. February has many of the finest plants in perfection; but Chrysanthemums have to be tied up, decaying stems to be removed, annuals trimmed up close to the stem, Stocks to be planted for flowering, bulbs that have done work to be taken up, and seeds to be saved. March is the bulb-planting month. Showy annuals are sown in vacant places, Roses are pruned, and Carnations planted out. In April much transplanting is effected before the cold dry wintry winds come. Bulbs are still planted and Roses propagated. Dahlias are taken up, tubers are dried, Stocks, Pansies, and Wallflowers are sown or planted, and the garden is kept clean. May brings the Camellia in flower; Hyacinths are planted, borders are manured, and the Roses attended to. Some Roses are for standards or dwarfs, the former ornamenting stony or clayey soil. The display of Roses at colonial Rose shows would astonish some European gardeners. June has cold nights in Queensland; so, especially in the south, choice flowers need protection against frosts, however hot the day when once the sun has risen. Softwooded plants for bedding-out are now propagated, and cuttings of Pelargoniums are taken. Dahlia roots are stored, grass plats formed, and hedges planted.

July, the coldest month, may sometimes, but very rarely, have a temperature of 30°. This is the spade and fork time, while flowering shrubs and perennial herbaceous plants are duly placed about. Roses are kept in bloom by pruning. Annuals and biennials are sown, and some bulbs, Gladioli, and Amaryllises, are planted. Fuchsias are increased from cuttings, and Begonias, Gloxinias, &c., have to be repotted. In August overgrown herbaceous plants are

divided. Rhododendrons, Azaleas, Daphnes, Laurustinus, Magnolias, and Arbutus are transplanted. The following are also now recommended to the colonial florist: Poinsettia, Weigela, Latania, Double-blossom Peach, Persian Lilac, Guelder Rose, Tecoma velutina, Escallonia, Poinciana, Erythrina, Lagerstræmia Clerodendron, Bouvardia, Datura, Gardenia, Tabernaemontana, Cestrum, Corchorus, and the Hibiscus.

September is a very gay spring month in Queensland, especially with Azaleas and Verbenas. These are admirably fitted to that climate. Layers of Camellias, Azaleas, and Magnolias are made, while Balsams, Cockscombs, and other annuals are sown, as well as Stocks, Asters, and Lobelias. The blooming Gladioli and Amaryllises require shelter from rough winds. In October the Roses are perfect, Dahlias are staked, Verbenas are planted, annuals are sown, and pot plants protected from insects, always pretty lively in Australia. November wants scythe and hoe. Climbers are tied up, herbaceous plants are cut down, and bulbs are stored; annuals and tender-foilage plants are transplanted in showery weather, and attention given to watering this dry month. In December the weeding is important; edgings are trimmed, climbers tied, and tall plants staked. Roses may be budded, Carnations propagated, and flower seeds gathered.

While Brisbane market is pre-eminent for fruit, it is especially delightful for its show of flowers all the year round. The colonists are proud of their flower gardens, especially of Australian fragrant and flowering shrubs, though patriotically devoted to the culture of those English varieties associated with early years and dear old friends. Queensland of late years has introduced a large variety of Chinese, Indian, Mexican, and Brazilian flowers, for the growth of which its fine climate is so adapted.—J. B.

KITCHEN GARDEN.

Cauliflower.—Plants will now shortly be ready for planting in handlights; select the most forward, pricking the others into frames. Good strong loam should be employed, as it promotes sturdy growth, and with proper attention to ventilation the plants will better endure severe weather. The lights should only be employed in case of frost, it not being possible to give too much air when the external temperature is above 35°. Examine the plants commencing heading, and break a few of the larger leaves over the heads to protect them from any sudden frost that may occur after this.

Lettuce.—For the spring and early summer supply Lettuces should be planted in rows 1 foot apart upon a sheltered border, or they may be placed in the spaces between the early Peas, which will shortly be sown, in rows 4 feet apart; rows of a Cabbage variety of Lettuce can be placed 1 foot from each side of the Peas, and a row of Cos in the centre. Where the soil is light it is necessary that it be made moderately firm by treading, and then rake the surface to render it even. Dust the plants with quicklime to destroy slugs. When the main crop of Lettuce has been planted a quantity of the Cos variety should be pricked out in a sheltered situation. Plants from the July sowing should ere this have been placed in frames or in ground where they can readily be covered; if not, the operation must not be longer delayed, planting the alternate rows of Cabbage and Cos 8 inches apart every way. The Cabbage varieties—Paris Market and All the Year Round—will be off before the Cos; Bath Cos, Sugarloaf, and every other plant of the Cabbage may be cut for early use. The lights should not be placed on until frost commences. In connection with this it may be stated that it will be necessary to provide accommodation for the Lettuce and Endive, which are to be lifted from the open ground to give a continuous supply when that outside is either exhausted or destroyed. The preservation of these in cold frames involves much labour and has often unsatisfactory results, so that where large supplies are needed shallow pits with moveable lights, and the command of sufficient artificial heat to exclude frost, are essential to provide salads in good condition throughout the winter months.

Cabbage.—The removal of the crops of Onions and Potatoes will

render the ground available for planting Cabbage; it should at once be prepared by digging and manuring if necessary. If large heads are wanted a distance between the plants of 20 to 24 inches every way will be required, but for ordinary purposes 18 inches will be sufficient. The plants must be protected from the ravages of slugs by dustings of quicklime, wood ashes, or soot.

Parsley in pits should be well thinned, but the pits may still be kept open except on frosty nights, when the lights should be put on and removed during the day. Where no other shelter can be had strong spring-sown plants may be carefully lifted and placed in deep boxes or large pots. These placed in an orchard house or vinery from which the Grapes have been cut will furnish a supply in severe weather. Chervil may be treated in a similar manner. In order to keep up a supply of the tender vegetables every aid or protection in the open air should be attended to in due time. The earliest crops of Celery should now be finally earthed-up, well beating down the banks of soil so as to exclude rain as much as possible. In case of sudden frost to take up and place under protection Cauliflowers which are fit for use. Examine Tomatoes on walls, &c., and cut them as they ripen. Should indications of frost appear it will be desirable to cut all Tomatoes that are of size, and lay them in a vinery or similar place to finish. Ply the hoe whenever the weather is favourable between the rows of growing crops, and keep weeds under, as every growth they make is only so much taken from the soil.

FRUIT HOUSES.

Melons.—The weather lately has not been favourable to the late crops, having been cold and wet, during which canker is most troublesome, and cracked fruit most prevalent. The best practice is to keep both the soil and the atmosphere dry, and to employ fresh-slaked lime upon the first appearance of canker. Cease syringing the foliage, and supply water only at the roots to prevent the foliage flagging. Remove all superfluous growths. The late fruits are swelling-off well and must be supported. Maintain a temperature of 70° to 75° by day artificially, and 65° at night, closing the house early in the afternoon at 80° to 85. After this time cease applying water to plants in dung-heated pits or frames; a dry condition at the roots will accelerate the ripening process. Any fruits that have finished swelling on plants that are dying should be cut with a good portion of stem and placed in a warm dry house to ripen.

Cucumbers.—Be liberal in the treatment of the plants for autumn fruiting to obtain a strong growth, as much of the after success depends upon the foundation now laid. Remove all staminate flowers and tendrils, avoiding overcropping, and be careful not to allow the fruits to hang too long upon the plants. Gradually reduce the atmospheric moisture as the days shorten, and employ the syringe only on bright warm afternoons. Earth-up the roots from time to time, pinching out the growing points of the shoots about every week or ten days, reserving as much wood only as will ensure the full admission of light, and in watering have it about the same temperature as the bed. The plants for winter fruiting should be in their places about the middle of October to ensure a good supply at Christmas. See that the heating apparatus is in thorough order, and complete the preparation of the fermenting material. Attend well to the requirements of the young plants, keeping them near to the glass to ensure sturdy growth, and be careful to test the heat of the bed before planting out. A bottom heat of from 85° to 90° will be safe, but the latter temperature should not be exceeded.

Figs.—The Fig trees in pots for early forcing must be attended to, examining the roots, and if needful remove a few inches at the base of the balls, cutting back the roots, and supplying fresh fibrous loam and a sixth of old mortar rubbish or road scrapings; also remove the loose surface soil, filling up with the compost above named, and a fourth of old manure; after that give a good supply of water, and place the trees where they can have plenty of air, but without being exposed to rain or frost. Trees in pots that have the roots extending into the fermenting beds and not started until early in the year will probably continue growing, and the roots should be cut through about a foot from the pots, and the plunging material removed to below the bottom of the pots. A slight syringing occasionally will be sufficient to keep down red spider until the leaves have fallen.

All unripe fruit should be removed, and a dry atmosphere maintained. Fig trees planted out should now be kept drier at the roots, which will tend to mature the growths, and as soon as the second crop is gathered keep the house cool and dry, ventilating fully except during frost. Where root-pruning or lifting is contemplated preparation should be made of the requisite compost—viz., turfy loam, with some old mortar rubbish added, and a sprinkling of half-inch bones, and these operations should be performed as soon as the leaves show indications of falling.

FLOWER GARDEN.

Propagation should now be finished, and the winter quarters prepared for receiving the plants, as sharp frosts may shortly be expected. Plants intended to be lifted should be protected upon the first appearance of frost. It is generally advisable to save most of the tricolor and other variegated Pelargoniums, and some of the flowering varieties, as they come into flower sooner and more freely than young plants, and are valuable for planting in vases, baskets, &c. On account of the comparative slow growth of tricolor, bronze, and other ornamental-leaved varieties it is not desirable to head them back, merely removing any crowded branches and stripping them of their leaves; the remaining shoots being left at full length will afford an early and plentiful supply of cuttings in spring. The green-leaved varieties should be cut back, have the roots trimmed, and be placed in small pots. The plants should have a dry atmosphere and a temperature of about 50°, to keep them slowly growing through the winter.

Calceolarias and Violas.—Cuttings of these may be inserted in frames with the lights facing north, and in an open situation as regards light, placing about 6 inches of rich soil in the frame, and over this about an inch of sharp sand. The cuttings should be from the base of the plants, short-jointed growing shoots of about two nodes and the growing point, inserting them 3 inches apart, and giving a good watering. The lights need not be employed until frost or to throw off heavy rains, when they should be tilted. Violas will strike freely inserted about 2 inches apart in nursery beds in the open, the soil being rendered firm about the cuttings and kept moist.

Plant out Pinks finally where they are to bloom, the ground being previously well prepared by exposure and frequent turning over. Pansies and Violas intended for early flowering should be planted at once. Place choicer varieties of Pansies under glass in cold frames. Finish planting or potting Carnation layers as soon as possible, protecting those in pots from heavy rains. In making up beds of Carnations, Picotees, and Pinks it is advisable to give a good dressing of soot and fresh-slaked lime before planting, to prevent the attacks of wireworm. Anemones for early flowering should now be planted, covering them 2 to 3 inches deep, and surrounding with sharp sand. Anemone fulgens is one of the most beautiful. The herbaceous or mixed border is a very suitable place in which to grow bulbous-rooted plants, as they are not disturbed and can ripen off the growth. Plant English and Spanish Irises about 4 inches deep in well-drained soil, and mulch the surface with leaf soil before frost about 2 inches thick. Gladioli of the ramosus section may also be planted about 6 inches deep as soon as corms can be obtained. Blandus, Cardinalis, Colvilli, and Colvilli albus are valuable for cutting; masses of the early-flowering kinds are really magnificent in June and July. Autumn Crocuses are very beautiful, as *C. nudiflorus*, *C. speciosus*, *C. odoratus longiflorus*, *C. byzantinus*, *C. etruscans*, *C. medius*, *C. serotinus*, and *C. zonatus*, with *Colchicum autumnale* vars., *C. byzantinum* vars., and *C. speciosum rubrum* in masses make an interesting display.

PLANT HOUSES.

Greenhouse.—From now until Chrysanthemums come in is the worst season in the year for flowers, therefore encourage late Fuchsias to continue flowering by regularly removing the seed pods as the flowers drop, and assisting them with weak liquid manure. Any late Gladioli that have not yet flowered may be taken up and potted in 6-inch pots, and will be ready for conservatory decoration, the lifting not interfering with their flowering. Dwarf Scabious may also be lifted and potted, and done carefully they will give a quantity of useful sweet flowers for cutting. *Schizostylis coccinea*

may be lifted and potted, and they will give a quantity of useful flowers over a lengthened period.

Zonal Pelargoniums.—Plants that have been well grown and are strong and well furnished, having had the flowers removed instead of allowing them to form, will be very useful, keeping them at the warmest end of the house, where they will receive plenty of light and will give a number of flowers for some weeks. Plants that have been specially prepared for winter flowering should now be placed in a house or pit where they can be kept rather dry until they are removed into heat to bring them into flower.

Cinerarias.—Plants from seed sown in spring will now be well advanced for flowering, and should be assigned a light position in a house with a temperature of 50°, and they will afford a useful supply of flowers for cutting, especially the self-coloured varieties—blue, crimson, purple, and white. The general stock should be kept cool and moist to ensure sturdy growth, fumigating moderately upon the first appearance of aphides. Plants in small pots should be given a shift, and as the flower head is being produced supply liquid manure.

Primulas should no longer remain in pits and frames, but be transferred to a light airy house and receive weak liquid manure. Abutilons struck in spring and grown on through the summer will be flowering freely, and should have a temperature slightly higher than an ordinary greenhouse to keep them growing and flowering through the winter. *Rochea falcata* does not sometimes open its flower head in an ordinary greenhouse, and may be given an increased temperature, in which it will display its bright heads of bloom unrivalled in colour at this season.

TRADE CATALOGUES RECEIVED.

S. Dixon & Co., 34, Moorgate Street, London, E.C.—*Catalogue of Bulbs.*

Wm. Paul & Son, Waltham Cross, Herts.—*Catalogue of Roses.*

Books (A. B.)—We can only suggest that you advertise the books you desire to sell, stating their condition and the price you want for them.

Gypsum (J. H. P.)—It is a combination of sulphuric acid and lime, and is a constituent of many cultivated plants, especially of the Clovers. It is sold by all dealers of manures.

Hedychium (M. H. W.)—The English name of the Hedychium is Garland Flower, but the species you mention is unknown to us. Are you sure you transcribed the name correctly?

Fruit Trees for Wall (F. J.)—Both Pears and Plums will succeed in the position you name, and the following are good varieties:—*Pears*: Williams' Bon Chrétien, Louise Bonne of Jersey, and Doyenné du Comice. *Plums*: Kirke's Victoria and Green Gage.

Propagating Violas (Idem)—Short sturdy-rooted slips, which will soon be plentiful, will form plants as good for massing purposes as those raised from cuttings; but the latter usually produce the finest individual flowers.

Enlarged Oak Buds (W. S.)—The very large and abnormal buds which you have sent are very singular. They are the result of the puncture of an insect, the cavity of which is perceptible quite in the centre of the mass and close to the growing axis of the bud.

Eucharis (Seventeen-years Subscriber)—The name, as is stated in the Supplement of the "Cottage Gardeners' Dictionary," is "from *eucharis*, agreeable, alluding to the fragrant flowers." Yours is probably an old edition of the Dictionary.

Allamanda Hendersoni (W. B.)—We have no doubt the plant, if it is not started into growth too early, will succeed in the house you name. An intermediate house during the summer is practically equivalent to a stove. We should not start the Allamanda quite so early as the Stephanotis, as the latter plant will succeed in a lower temperature than the former.

Dendrobium nobile (J. B.)—You had better remove the plant into the other house as you propose, assigning it a position near the glass, where it can have all the light possible. Only water it sufficiently to keep the foliage fresh, and the growths will become firm and flowers show in the course of a few weeks, when it can be again placed in the warmer structure.

Grass in Orchard (F. E. D.)—If the second crop is heavy it would not be wise to leave it on the ground; but if light it might not do any harm, nor do we think it would do much good. As you do not want it for hay it might be placed in a yard with pigs or other animals, and converted into manure. If it cannot be so used place it in a heap until it decays, and then have it dug into the land.

Seeds and Plants for Garden (A Reader)—If you will state full particulars as to the size, aspect, and character of your garden, also whether you

require annual or perennial plants, with the particular time, if any, that you require a display, and further whether you have beds on a lawn or gravel that you require to be filled on the massing system of one variety of plant in each bed, or desire the plants to be grown in mixture—if you will state such essential particulars as these we will readily advise you on the subject, but in its present form your question is unanswerable.

Wintering Chrysanthemum frutescens (E. C.).—The plants may be wintered safely in a light position in an ordinary greenhouse. If they are planted out you should take up a few of the best and most sturdy at once, prune them slightly to render them compact, and pot them in good soil. Cuttings may yet be struck, inserting them in sand and placing the pots in close and moderately heated frame or pit. Old plants yield cuttings in abundance in the spring, which strike with great freedom in moist sand in a heated frame or propagating house.

Figs Cracking (Horace).—The cause of the fruit parting at the apex into four divisions is too much water at the roots, and too close and moist an atmosphere. When Figs are ripening, the trees require to be kept comparatively dry at the roots, but not so much as to distress the foliage; a free circulation of dry warm air is also needed. This is not only necessary to prevent cracking, but is essential to quality and flavour. The most useful Fig for growing in heat, or indeed for any purpose, is Brown Turkey, and if you require a white companion for it grow White Marseilles.

Vine Leaves Withering (Berwickshire).—It is not uncommon for the leaves to fall prematurely from young Vines that have made very strong canes, and it is not often that any serious injury results. The best leaves sent appear very healthy, but some of the others show unmistakable signs of scorching. We do not think the Vines are "attacked with a disease." You have perhaps been "pushing them on with fire heat," and possibly sun heat, rather too fast. Admit more air, especially early in the morning.

Disbudding Camellias (Park Hill).—Undoubtedly a great number of the buds must be removed, but we should remove them by degrees, and very carefully. If the plants are vigorous they will support two or three flowers on each shoot, but if fine blooms are coveted one on each shoot will be sufficient; the final thinning, however, should not be done until the approach of spring, as from various causes some buds not infrequently drop during the winter. Remove one-third of the buds now, and the others at weekly intervals until they are reduced to the requisite number for expanding.

Cyclamens Unhealthy (R. P. O.).—As the plants are just coming into bloom, we regret that we do not know of any mode of destroying the maggots at the base of the corms without at the same time despoiling the plants of their beauty. Very old corms are not infrequently affected in the manner you name; but if your plants are young we cannot account for the presence of the maggots, unless they were in the soil when it was used. You had better raise a fresh stock of plants from seed, which may be sown now if you have suitable heated structures for growing the seedlings.

Grapes for Greenhouse (Inquirer).—The term "greenhouse," as applied to Grape culture, is very indefinite, as there are structures of that name in which the requisite temperature can be produced to ripen most varieties of Grapes. We can only say that the following Grapes having a Muscat flavour will ripen in vineries that are not usually kept at a hothouse temperature—Meurthe Frontignan, Venn's Black Muscat, and in fine seasons Bowwood Muscat. Troveren Frontignan requires more heat to produce it in good condition.

Planting a Grave (J. M. B.).—We do not think your proposed plan of planting will answer your expectations. Assuming that both the Snowdrops and Crocuses would grow well, the foliage of the former would quite hide the design of the latter. If you desire to have Snowdrops you might plant a broad margin with them round the grave, forming the design in the centre as you propose with Crocuses. If the bulbs are covered 5 inches deep with light soil you will then be able to plant, with care, bedding plants in summer. After these are cleared off in the autumn a layer 4 or 5 inches in thickness of decayed manure should be spread on the surface. The rains will wash the beneficial portion of this to the bulbs, and in the spring the manure will have changed almost to black soil, and will be exactly suitable for the bedding plants. The bulbs cannot be planted too soon; many failures ensue by deferring the planting of Crocuses until the corms have grown considerably, when decay often ensues.

Early Produce for Market (R. R.).—Fruit, flowers, and vegetables are largely forced for market purposes, and those who are acquainted with the peculiar nature of the work appear to succeed very well. We do not consider it safe to advise a man who has been exclusively employed in gentlemen's gardens to invest his savings in trying to establish a trade of this kind without being practically acquainted with the general conduct of the business as it is practised in the neighbourhood of London. Competition is very keen, and special knowledge is needed to attain success. Most of the growers for the London markets confine themselves to the production of either flowers, fruit, or vegetables, but we believe among others Mr. Elliott of Fulham grows them all more or less extensively.

Paulownia imperialis (Winchester).—The leaves you sent appear to be those of the above-named Japanese tree, which in habit and foliage resembles Catalpa syriacaefolia, but differs structurally, the latter being allied to the Bignonias, while the former is included in the natural order Scrophulariaceae. The tree was originally discovered by Dr. Siebold, and was introduced to this country in 1840. It has been planted somewhat extensively in Paris, where, and in the south-western parts of England, it is very ornamental, owing to the fine foliage and purplish-lilac flowers that mark the species. The flowers are not, however, very frequently produced in unfavourable positions, and in the neighbourhood of London they are rarely matured, the tree often being injured by frost. A moderately light dry soil and a sheltered warm position seem to suit the Paulownia very well.

Melon Leaves Decaying (J. G.).—It is very difficult to account for injury to the plants in the house while those in frames remain healthy. Is the bed chambered and heated wholly with hot-water pipes? If so, there is a probability that the roots when they reach the slates, or whatever the pipes are covered with, are injured by heat or drought, while the bulk of the soil in the bed is in good condition. Is the glass of the house different from that of the frames? If the former is very common and full of lenses the leaves under it would be scorched and blotched. Do you syringe the plants rather late in the afternoon, or damp the house freely then? We gather from your letter that the front ventilators are left open at night and the top ventilators are closed. We should reverse this mode of ventilating, and not allow the temperature to fall below 65° at any time. If there is much moisture in the house and the temperature is low in the morning there will be a condensation of moisture on the foliage, and the sudden evaporation following the opening of the top ventilators after the sun has been shining on the house for some time would result in injury to the

foliage. The injury, we think, arises from one of the causes we have indicated, or possibly a combination of them.

Vine Shoots Injured (Flectwood).—We sent for the Vine leaves expecting to find them infested with thrips, which when numerous often attack the young growths and destroy the epidermis. But there were only two of those insects on one of the leaves sent, which circumstance does not indicate that thrips are sufficiently numerous to have caused the injury, unless, indeed, they are more plentiful on some other leaves that we did not see. The affected portion has been subjected to careful microscopical examination, and not a trace of fungus can be found. We conclude that the injury is either the result of the puncturing of some insects, or the shoots have been in contact with something poisonous to their tissues. The Vines are evidently unhealthy, the leaves lacking substance, and the wood being very unripe. You do not inform us as to their age, condition, the treatment which they have received, nor the wires to which they are trained, all of which particulars would have been of assistance to us in endeavouring to find the cause of the injury.

Ficus elastica Unhealthy (S. A. P., Clevedon).—The discolouration of the foliage is either the result of the plant having been too dry at the roots at some time (it may have been months ago), or the plant has been removed from a shaded to a more sunny position; or again, it was injured by the extreme cold of last winter. Hundreds of plants in the windows of sitting rooms have lost their foliage this summer—a certain result of the extreme cold of the preceding winter, while hundreds more were killed by the frost gaining access to the rooms. As you do not state the conditions under which your plant was grown we are unable to give you a more precise reply. If the plant is very large, while the pot in which it is growing is small and much crowded with roots, watering it twice a week with weak soot water will be beneficial. If you tie up a handful of soot in a piece of canvas and suspend it in a pail of water for a week you will have an excellent stimulant for your plant. The soot water may need diluting. It should be of the colour of pale sherry when used, and quite clear.

Potatoes and Melons (Old Subscriber).—1, It is not necessary to allude to a clerical error that has not misled you. 2, Bedford Seedling is correct. 3, Maumoth Pearl is the name of the Potato. 4, We have answered the question relative to the Melon clearly and accurately, and have nothing more to add. 5, We have no official list of the awards. Wormleighton's Seedling is possibly correct, the eard, as is often the case at exhibitions, having perhaps been placed on the wrong dish accidentally and afterwards corrected. When the report of a show has to be in print two or three hours after the completion of the judging it is obviously impossible to verify the accuracy of every name and award. In this case all the cards were not placed on the dishes until 1.15, and the report was in the printer's hands at 2.30—an hour and a quarter after the judging; so that if there were only two errors, and one of them a comma, our reporter may be complimented rather than otherwise on his work. In two of the gardening journals Wiltshire Snowflake is credited with having received the first prize in the new variety class, and in two others Wormleighton's Seedling. The name of this variety, as you have quoted it, has not appeared in any gardening journal.

Names of Fruits (H. P.).—The Pear is Caillot Rosat; the Plum is Nelson's Victory. The Peach we cannot name without the leaves and the flowers. (R. Adams).—It is not Jefferson Plum but Transparent Gage, a most delicious variety. (Henry Berry).—It is Diamond Plum. (Henry Riches).—1, Beurré Diel; 2, Duchesse d'Angoulême; 3, Beurré d'Amanlis. The others are not yet in condition for naming. (George Swales).—Please send wood, foliage, and fruit of the Apple as you propose, also of the other variety if possible, and we will submit them to close examination.

Names of Plants (X. X.).—1, Polystichum angulare proliferum; 2, Lastrea dilatata, may be by some called a variety, certainly not the Hay-scented Fern; 3, Cystopteris fragilis, Brittle Bladder Fern; 4, Cystopteris fragilis var. dentata. We have recently seen it in Scotland, and it seems to be intermediate between C. fragile and C. Dickiana; 5, Athyrium Filix-femina, Lady Fern; 6, Polystichum angulare. (Winchester).—Paulownia imperialis. (Arthur Paine).—Zephyranthes candida. (D. B.).—We do not undertake, as we have often mentioned, the naming of varieties of florists' flowers; but we have no objection to state that the crushed Fuchsia flower we have received resembles Earl of Beaconsfield. (W. C. B.).—1, Very unsatisfactory specimen, but it resembles Paullinia thalictrifolia; 2, Selaginella cuspidata; 3, Selaginella Martensii; 4, Adiantum hispidulum; 5, Selaginella Galeottii; 6, Adiantum tenerum. (W. Begbie).—Mentha piperita. (G. O. S.).—The specimen appears to be a good form of Lathyrus latifolius var. ensifolius. (Reaster).—1 and 2 cannot be identified without they are bearing spores, as we previously informed you; 3, Tropaeolum speciosum. (E. D. C. I.).—Lobelia fulgens ignea. (D. J. N.).—Sedum spurium.

POULTRY, PIGEON, AND BEE CHRONICLE.

SHED ACCOMMODATION FOR CATTLE.

(Continued from page 294.)

OUR further treatment of this subject would by no means be so complete as we could desire, unless the question of farmyard economy and the best form of farmstead as a whole are fully considered, but more especially that portion relating to covered yards or farmsteadings. We have gone rather minutely into the question of box feeding, yard and shed feeding, &c., with accommodation for cattle, in former parts of these remarks as being necessary in themselves, and also as parts of a set of buildings for farming purposes. It is now, however, our intention and wish to take up the matter so that the farmstead may not only

be well placed and covered-in, but considered also as to the best mode of placing the different apartments in the buildings in relation to each other. This attention is needed to form an economical farmstead whereby the cattle shall be best preserved in health and condition, and the farm produce—whether of hay, straw, roots, &c., together with purchased foods for cattle—shall be so expended as to preserve the most valuable portions of the manure arising from their consumption in the most useful state and condition. There is, too, another point—that of economy, to be considered in the cost of these erections which come within the term of farmsteadings.

For the purpose of explaining our subject we shall refer to essays and plans of farm buildings which have on several occasions been in competition for prizes offered from time to time by the Royal Agricultural Society of England, and also refer to papers which have been read and discussions entered into at the meetings of the Council of this Society. We feel justified in assuming that in these contests for prizes, and the discussions upon the subject, are included the best designs for farm buildings that have ever emanated from the most intelligent agricultural architects, and the most clever and practical farmers to be found in the kingdom. In the year 1849 prizes were offered by the Royal Agricultural Society for the best constructed farm buildings, which brought out various competitors. The prize plans, the highly commended and other competing plans, were all very valuable at the time—in fact, they may even now be examined with interest and advantage, as they are shown in the Society's Journal for the year 1850. The late Mr. Fisher Hobbs and Lord Kinaird have both furnished valuable essays upon the subject, which will also be found practically described in the Royal Agricultural Society's Journal also. We must call attention to the paper and plans produced before the Council of this Society on the 18th of June, 1862, by Mr. John Elliot, architect of Southampton, which exhibited some novel and important points not to be found in any previous plans and statements referring to these subjects; but it was left for the Royal Agricultural Society to crown their endeavours to obtain the best and most important information by offering prizes for plans of farm buildings at the London International Exhibition in 1879. On reference to the report of the Judges as to the plans submitted for competition we find that it was most extensive—in fact there were sixty-eight sets of plans sent in for competition from thirty-nine different authors, of which only three sets were disqualified as not fulfilling the conditions required by the Society. No prizes, however, were awarded on this occasion, principally on account of the cost; but at the recommendation of the Judges a high commendation was given to the plans of Mr. W. E. Keates of Hanley, Staffordshire, which represented a homestead and dairy arrangement suitable for a farm of mixed arable and pasture land of 400 acres, a description of which, with a ground plan and isometrical view, is given amongst five others, with a full description by the authors, not only of the objects and purposes of all parts of the buildings, and with detailed estimates of the materials required in the erections, but also as to the total cost. In considering the cost of the buildings, as shown by Mr. Keates's plan, we find that Mr. Bailey Denton, in his report as one of the Judges, says in this case the estimate of the competitor himself was £6146 for homestead and dairy, exclusive of the dwelling house, road approaches, and contingencies, which, together with architects' charges, would raise the outlay on this farm of 400 acres to upwards of £18 per acre. Such a charge the Judges considered no farm of this size, even if it consisted of the best land and commanded the best market, could bear without loss to the owner, let attendant circumstances be what they may. It therefore appears if we are to take the commended plan entirely for our guide in erecting buildings on a farm, it could not be done except by

making an injudicious outlay; we will therefore endeavour to make some comparisons between this plan and that of Mr. Elliot and others which deserve notice, in order to draw some conclusions therefrom in the interest of the home farm, or any farm in fact. We can, however, only allude to either, in the absence of plans, to the general advantage or otherwise of the system involved in management, and the style and cost of the buildings, which our readers perhaps will scarcely understand sufficiently without reference to the plans themselves, as given in the Royal Journal for 1879, also for 1850, 1862, and the *Agricultural Gazette* of November 4th, 1878, the last-named giving a plan of the dairy homestead designed by Mr. Gilbert Murray, which obtained the first prize at the London Dairy Show in October, 1878.

The first point we will consider is the site of the homestead; and we think it should neither be too highly elevated and exposed, nor yet low enough to be below the fog level; at the same time it is well that it should be placed near some pasture land at a lower level, in order that the drainage both of liquid manure and the rain water from the buildings may fall of their own gravity to the pastures for the purpose of irrigation. After all the arrangements which we have proposed for utilising the liquid manure there is nothing equal as a matter of economy to its use for watering grass land, but the rain water being mixed with it on entering the pastures serves to dilute it, and distribute over a large area of land. Nearly all the plans exhibited arranged for the corn and hay to be stacked near the buildings; but we consider that a better plan is to stack the corn, &c., in the fields where grown, except in a field or two near the farm premises, and not extend the time of securing the stacks in our fickle climate, for we would sooner carry the straw and hay to the homestead as required than that the corn should be ricked at the homestead, the former being done without risk, and at a leisure time for horses and men. Let us take Mr. Keates's plan of buildings first. Now we find stalling for cattle, horses, the piggeries, and also the barn implement shed and other farm offices very fairly placed in relation to each other; but we do not approve the position of the dung pits, although they are a necessity whilst three or four yards are retained in the plan. Now, these are covered it is true; but are they required or necessary when ample accommodation for all the stock is well arranged, and the drainage and ventilation well provided for, as it is in this case? We think not, and consider that the great expense incurred by covering these yards is, under the circumstances, a great defect as compared with other homesteads. On referring to the plans exhibited in 1849 for the Royal Agricultural Society's prize, which was awarded to Sir Thomas Tancred's homestead, and which is made up of detached buildings with uncovered yards between them; and although the boxes and stalls, stables, &c., are good, we find that a fixed engine only is provided, and a large collection of corn stacks in the rick yard near. Our object in naming these points is to show the contrast with more recently approved systems. We, however, think the award was an error, and that the commended plans furnished by Messrs. Spooner and Elliot contained fewer defects and offered more advantages. For instance, the cattle boxes and the tramways were more convenient and better placed, with improved roofing and ventilation; still there was in these plans the open yards, the fixed engine, and the collection of ricks to which we have previously objected.

We must now refer to the entirely covered homestead by Mr. Elliot, plans of which were exhibited at the Council meeting of the Royal Agricultural Society on the 18th of June, 1862, and the advantages of their construction and position was explained by an illustrative statement read by the author, and which at the time raised a discussion amongst the members, and generally of approval by the practical men. As space will not allow us to go into the minute details of the plan we will endeavour to furnish

an idea of its advantages. The buildings may be constructed in two ways—with brick, wood, iron, glass, &c.; also with brick, iron, glass, &c., entirely. The latter proposal is to make the buildings fireproof, all except the barn and its surroundings, which would contain straw, hay, corn, &c., the burning of which would fuse the metal if constructed of brick and metal only. The large amount of value in live stock which may be in the buildings would therefore not require to be insured against fire. The main block of the buildings consists of accommodation for cattle, and is but an aggregate of distinct areas, each of 12 feet square. There are two double ranges of boxes and two single ranges, with four tramways for the conveyance of food and litter and the removal of manure. The elongated block of the building runs east and west; the horse boxes are on the north side, each 12 feet square, excavated 18 inches, so that one box will accommodate one horse with manure accumulating under it, or filled with earth will afford room for one only or two tethered, and the manure removed daily. On the south side is a range of spaces under cover for young stock, pigs, &c., and a lambing yard for ewes. The other or central boxes afford space for fattening bullocks, fattening pigs, &c., and are capable of being used for all the purposes required on the farm, such as dairy cows, mare and foal, &c. The whole of the internal fittings being of iron framed as required are removable at pleasure, when the whole area may be used as a covered farm-yard; but this will not be required in these days. On the western end of the site is the barn, surrounded by lean-to buildings, as root, hay, straw, corn, and meal stores, also the house for a portable steam engine, for when not employed in cultivating the land it is easily placed, and used for thrashing corn at the barn, and giving also motive power to the root and chaff-cutters, &c. The cattle food when prepared is taken to the cattle boxes by three tramways with turn-tables, each leading into the central building across a gangway of 20 feet, thus cutting off fire if it occurred in the barn. At the east end is the covered dung pit, implement shed, drill house, and artificial manure store, with tramways leading from the boxes across a gangway into the dung pit. The roofing of the building is of iron and glass, and well ventilated by its peculiar construction. These buildings, which will cost about £2200, are chiefly intended for a farm of 400 acres, consisting principally of arable land.

WORK ON THE HOME FARM.

Horse Labour.—Some horses may still be employed in working the land under autumn fallow, in order that the couch and weeds may be removed which had been previously brought to the surface. The carting of dung on to the fallows and lea ground in readiness for ploughing and ridging-up as a preparation for sowing with Wheat will be continued, the late rains having greatly improved the condition of land for ploughing. The fallow land and that where roots have been fed off will come up closer and firmer; also the Clover leas, which have lately been rather dry and hard, can now be ploughed easily, and enable the land to be laid more correctly when turning the furrows. The Rye and Trifolium, Vetches, &c., will by this time have been sown. The horses must now be employed in preparing and drilling winter Beans; 2 feet apart is the best distance, and half a bushel of winter Vetches per acre will answer a good purpose if drilled with the Beans. The next work will be ploughing for Wheat, especially upon the chalk hill farms, where the Wheat ought to be sown earlier than in the vale farms. The management of horses at this time of year is very important, because after they cease feeding off green fodder it is wrong for them to depend entirely upon dry food, such as Oats, Beans, and hay alone, and therefore allow them roots of some kind, not exceeding, however, 10 or 12 lbs. daily, and if pulped and mixed with hay chaff it will assist them very much, especially whilst the seed time for Wheat continues. The best roots are white Belgian Carrots, Parsnips, or early sown Mangolds; but Cabbages, common Turnips, or Swedes will do better after Christmas, when the animals have become accustomed to root-feeding. The foals which dropped in May and previous may now be weaned and allowed a hovel and small yard attached. If two run together so much the better, for they are always quieter when kept in pairs and do not attempt to break out when they have companions, especially if they are regularly fed with green fodder or pulped roots. Carrots are best, hay chaff, bruised Oats, and a little scalded bran mixed with other food during the first fortnight of weaning. They should also be placed, if it can be so arranged, as to be out of sight of other horses which may be passing to and fro through the farmstead.

Hand Labour.—The men will be spreading manure, filling dung carts, collecting couch on the fallows and filling into carts, also assisting in turning over the swarths of Clover which may have been held over and cut for seed, and assisting at carting and stacking the crop as soon as it is pronounced dry enough by the home farmer to be in saving condition for carting to rick. It is a common saying that the land after a crop of Clover saved for seed should not be sown with Wheat, but be held over for Oats or Beans until the spring, in consequence of the land being impoverished by a seed crop. But this is an error, for the roots of Clover are the nourishment for the Wheat crop, and it is proved that the weight of roots is much greater per acre

after a crop of seed than when the plants are cut for hay or fed off by sheep. Dairy cows should now receive Cabbages when they come to the stalls at milking time, or else have some strewn over the pasture where it is bare. If no Cabbages or other roots are available at this time they should get 3 or 4 lbs. of cake each per day. This will not only add to the quantity of milk and extend the milking period, but improve the quality of the milk and maintain the condition of the cows. The weaned calves and all young stock should also get a little food beyond that obtained from the grass land, and should either lie in the sheds at night or upon a high dry pasture well sheltered. It is at this time of year that young dairy stock are so subject to the quarter-ill or kill-calf if allowed to remain at night time on the meadows and pastures below the fog level. The sooner the animals intended for stalling or boxing to be fed for beef are placed in their winter quarters the better, as they will consume their allowance of cake, &c., with but little benefit if left out in the pastures at night beyond this period, even if they get plenty of grass upon a rich soil. If the home farmer requires to buy bullocks for winter feeding let him buy those in good condition; in fact, at this time of year when the farmers in the grazing districts are selling off, cattle just beneath the quality required by the butchers can often be purchased and fed in boxes to much greater profit than poor animals. The stocks of down ewes have offered to the ram well so far, and they will continue to remain together for another month. The long-woolled ewes, too, should have the rams running with them for the next seven or eight weeks, and in case their lambs are to be sold in the Metropolitan Market the rams should be of the horned Dorset or Somerset breed. The lambs will not come horned, but there will be numerous twins, and the coats of the lambs will be much closer and firmer—so desirable in the eyes of the butcher. The horned ewes in their native counties of Dorset and Somerset will now be heavy in lamb, and will be travelling to the fairs for sale. The best place to obtain them is at the Appleshaw and Wayhill fairs in Hampshire during the first and second week of October, where they are sold in great numbers. But the very finest ewes from the choicest stocks are often purchased on the farm where they are bred, and sent up into the home counties for rearing the house lambs and the early supply up to Easter.

ADVANTAGES OF A HOME FARM.—No. 2.

SOIL ADAPTABILITY.

THE first thing to take into consideration is the nature of the soil, as the basis upon which all our efforts depend, the indicator to guide all our subsequent culture, as well as our purchasing of stock. For example, on a deep loam or rich alluvial soil we would endeavour to form a herd of cows of a good strain of milky Short-horns, but on light shallow soil Kerrys would be altogether preferable. So, too, would our arrangements for culture be effected. On a plain with level square fields steam tackle could be used advantageously, but upon the hill farms we must revert to horses. The undulating surface of some of our farms here in Sussex is extraordinary. I have had three gangs of haymakers at work in a meadow of 8 acres, and each gang would often be out of sight of the others in some of its numerous hollows! On such land steam ploughing is out of the question; light iron pair-horse ploughs answer best, and do as much work with equal efficiency as the heavy old four-horse ploughs used to do upon the wealden clays. I will refer to

DRAINING THE LAND.

Drainage is of vital importance, and should be thorough in every part of the farm, both pasture and arable. Much ignorance still exists concerning the philosophy of this simple operation. I have seen land laid down for permanent pasture after corn with the ridges and water furrows unlevelled, yet not one pipe drain was laid in the whole meadow, notwithstanding the frequent complaints of how cold and wet it was, how soon growth ceased, and how badly stock did upon it.

Upon the home farm here the whole of the land has been drained, principally with 2 inch pipes, not with invariable success, our difficulties being greatest in bogs and steep slopes where springs abound, bursting out occasionally in unexpected places. A little extra pains and the application of 4-inch pipes is generally sufficient as a remedy. Bad workmanship is frequently a cause of failure. The ordinary method of beginning a drain at the lowest point, laying down the pipes and covering them with the excavated soil, which is thrown upon them as it is taken out to make the drain, so that the process of excavation and refilling is simultaneous, is so expeditious and economical that it cannot be set aside; yet it is objectionable upon the score of the facility with which it enables a careless workman to conceal any defects at once. It is therefore advisable to pay a good price, to exercise a close supervision, and to prove each drain before the upper end is closed.

One of the especial benefits of drainage is warmth. Thoroughly drain waterlogged soil, and an elevation of its temperature and of that of the atmosphere in its immediate neighbourhood soon

follows. This natural sequence has been called in question. "To raise atmospheric temperature you must drain by the square mile, a few acres would be like a drop in the ocean, and would do no good," has been said by those who cannot stoop to see the good of little things. Probably persons living in a flat country find a very equable temperature over a wide district. Here in hilly Sussex we have a difference of 3° or 4° in 200 yards, and a difference of 10° within five miles!

Some six years ago I had to deal with a piece of bog which will serve as an illustration. Its area was about 6 acres; half was fenced off for an ornamental bog and left undrained, and the remainder was drained and added to an adjacent pasture. Main drains 4 feet deep, with plenty of diagonal branches of 3-inch pipes, were made from a stream well up to the higher part of the bog, the trenches being 18 inches wide and half filled with alder faggots covered with soil and turf. The effect has been remarkable. In the ornamental undrained portion Bog Cotton, Asphodel, Sundew, Bog Campanula, and a host of kindred plants continue to flourish, Sedge Grass and common Rush abound, and hoar frost is visible early in autumn and late in spring upon its cold sodden surface. The drained part, on the contrary, has undergone a total change. Rushes have almost disappeared, the coarse herbage has become fine, the surface dry and warm, and its general appearance is so like that of the ordinary meadow land that no difference is perceptible. Some of the bog drains will eventually have to be taken up, cleansed, and relaid, for they exhibit a decided tendency to become choked by an ochreous deposit caused by the action of air gases upon those contained in the water drained from the ferruginous boggy soil. Science is of use here in showing us that this is a natural result, which, however vexatious, is not attributable to faulty workmanship, and which would prove decidedly profitable could one obtain enough of the deposit in the pipes, for it is undoubtedly a purer form of ochre than is often found in commerce.—EDWARD LUCKHURST.

POTATOES IN YORKSHIRE.

It is many years since I became a subscriber to "our Journal," and there is no periodical that I subscribe to which I anticipate with more pleasure than my Thursday's Journal. Glad was I when you found a corner for the "Home Farmer," although I would rather he would advise us poor tillers of the soil in the northern counties, to which some of the instructions do not apply. I should like to add my quota on strong-growing Potatoes. I agree with the majority of your correspondents that in a wet season there are no varieties free from the disease, though, no doubt, Champions and Magnum Bonums have proved themselves the least so, at all events hereabout; but what shall I say of the quality? I had yesterday a dish of Champions and one of Regents cooked for test purposes. One was a ball of flour, the other (Champions) was floury certainly, but not the colour to a lover of a mealy Potato, and the flavour was not so good. The "Bonums" are worse in quality though an excellent cropper. Last year I cut six sets to separate eyes, planted them at the same time in the field with the others, all being manured alike, and the produce was twice as much as the two rows on either side of them, and not one diseased, whereas the others were very much so. Yet notwithstanding their disease-resisting properties, those varieties will not, in my opinion, become popular in more genial seasons, for like Mangolds and some of our gross-headed Swedes they take too much out of the land, and it is not very difficult on a following crop to point out where they have been planted. On the cause or prevention of the disease we are here no wiser than others; but we do prevent it to a certain extent—by "heaping" we call it. After the plants are earthed with the plough a man takes the stem in his hand, whilst another puts a spit of soil upon the crown of each root; this prevents the rain running down to the tubers. For manure I find nothing answers better than spent hops mixed with fold manure, with soot at the last earthing. I sold one field five weeks ago, as I was afraid with the wet we were then having they would not stand. My surmises were right, but since then we have had three weeks' fine weather up to the 18th; since it has rained every day. But what was my surprise as well as pleasure when I went into the field to-day to hear the purchaser say they had not gone any worse than they were a month ago. I went also into a field of one of my neighbours, who reported the same; so that it would appear though a crop be struck with disease, if very fine weather ensues it will be checked.—A WEST RIDING GROWER.

THE WORCESTER POULTRY SHOW.

THIS Show was as usual held last week during the great Hop market, not as last year in a fine hall, but in a long marquee erected

close by. The Exhibition was entirely of chickens, and a glance round it confirmed our belief that the year has been a very propitious one for young poultry.

Game are always a great feature in this district, and headed the list. A special prize of Worcester china went to a capital Black Red cockerel belonging to Mr. Owens; the same gentleman also won first in pullets with an excellent Black Red; the second pullet, too, a Brown Red, was good. First among the cockerels, "Any other variety Game," was a Duckwing. There were several good Piles in this class. The first pullet also was a Duckwing.

Cochins.—The first Buff cockerel was a very well-shaped bird, a good yellow throughout in colour with fluffy hocks; second we did not admire, he was ragged and deep in moult, with too much hock, but certainly promises great size; third too dark in tail, but a promising cockerel. The cup pullet was a beauty, of a fine Canary colour, broad, deep, and forward. 76 very highly commended (Darby), a rich-coloured bird with splendid foot feathers, we should have put second. In the other cockerel class a Partridge was first, lacking neck hackle, but a fine bird in form; second, a White with a pretty comb; third, a Partridge, a short-legged bird, very bright in colour. In pullets first was a beautifully marked Partridge; second, a rather leggy Partridge; third, a pretty but small White; a good Black very properly had an extra prize.

Brahmas.—The first Dark cockerel promises to be a very fine bird; his breast was ticked, and we were glad to see that birds so marked win again. We liked the second as well as the first save that he is smaller; third was quite a chicken, and we thought very promising; the black-green of his plumage was particularly good. Mr. Comyn's very highly commended bird is one of the largest cockerels we have ever seen. 123 (Mrs. Turner), a fine bird but out of condition. In Dark pullets first was good in shape, the white of her ground colour and the black of her pencilling particularly clear and good; second also well marked but very leggy; third far too much hocked. The first Light cockerel was very good in colour but a little narrow; second, magnificent in size but somewhat yellow, and hocked; third, a clearly marked bird with too much tail. The Light pullets were remarkably fine and forward, all the winners were excellent; first was all round a most beautiful bird.

French made two very fine classes; the first cockerel was a magnificent Crève, but with one centre toe twisted to deformity; second, a Houdan, very fine in head; third, Houdan, capital in shape but with bad feet. The first pullet was a Houdan, beautiful in crest and beard; second a Crève. Mrs. Lane's very highly commended Houdan was very fine.

Dorkings.—There were some remarkable chickens in the class, and such as for size and maturity would a few years ago have astonished us. First were a good pair of Silver-Greys. Too often judges think that the Dark variety must necessarily always have first prize; in the present instance, however, we thought one or two of the Dark pairs better than these Silvers; second were very large and forward Darks; third, Darks, the cockerel a short-legged and massive bird; extra third, a beautiful pair of Whites such as we have not seen for a long time.

Spanish were few; the cup birds showed great quality of face.

Polands.—First, good White-crested; second, Golden, the pullet with a magnificent crest; third, Silvers.

Leghorns.—First, White; second, very large Brown.

Any Other Variety.—First, very fine Black Minorcas; and third, fine Scotch Greys.

Game Brahmas made immense classes. The cup went to a very stylish Black Red cockerel, and splendid in colour, but drooping his wings when we saw him.

Any Other Variety.—First, a large creamy Silver Sebright cockerel; second, a White, rose-combed; third, a Golden Sebright. In the pullet class, too, we were glad to see that second went to a White again. The breed is little patronised now, and very pretty.

PIGEONS.

September is not a good month for showing Pigeons. The winning Carriers were all black. Some of the Pouters were very, deep in moult. Dragoons were very numerous; first, a very good Blue. In Barbs Mr. Baker carried off all the prizes; first and second Blacks; third, a fine Red. *Jacobins*.—First, a Red, very good in hood; second, a very good Black. *Turbits*.—First and cup, a Red, beautiful in head properties; second, a Black, very clean in thighs and lustrous in colour. *Owls*.—First, a White African; second, the same variety; third, a Silver English. *Tumblers (Short-faced)*.—Mr. Baker's Almonds won; *Long-faced*.—A pretty Red rosewing, first. *Fantails*.—First and second, beautiful little birds, with round tails and good action; third, a superior bird but not in such condition. *Antwerps*.—A very good Silver Dun was first in the Short-faced class. *Any Other Variety*.—First, a capital mottled Trumpeter; second, a Black Turbiter; third, a Blondinette.

POULTRY.—*Game*.—Black or Brown Red.—Cockerel.—1 and Cup, R. A. Owens. 2, Robert Dance. 3, T. M. Hopkins. *Any other variety*.—Cockerel.—1, R. A. Owens. 2, S. Matthew. 3, W. Lodge. *Any other variety*.—Cockerel.—1 and 2, A. G. Potter. 3, J. Colgrove. *Any other variety*.—Cockerel.—1, T. Dyson. 2, S. Matthew. 3, J. Colgrove. *Any other variety*.—Cockerel.—1, Butler Smith. 2, Rev. H. B. Southwell. 3, Lady Allsop. *Any other variety*.—Cockerel.—1, Nichols, Miss. Molineux. G. H. Wood. *Any other variety*.—Cockerel.—1 and Cup, Mrs. E. Lang. 2, Lady Allsop. 3, Thomas Seal. *Any other variety*.—Cockerel.—1, Alfred E. W. Darby, Messrs. Cockroft & Danby. *Any other variety*.—Cockerel.—1, C. Sedgwick. 2, Miss Bullock. 3, W. W. Beckerley. *Any other variety*.—Cockerel.—1, C. Sedgwick. 2, C. Brown. 3, Miss Bullock. *Any other variety*.—Cockerel.—1, C. Sedgwick. 2, C. Brown. 3, Miss Bullock. *Any other variety*.—Cockerel.—1, E. Kendrick, jun. 2, E. Pritchard.

3, G. B. C. Breeze. *vhc*, A. Comyns, jun., F. Bennett, Marchioness of Hastings, Dr. J. Holmes. *Pullet*,—1 and Cup, C. Davenport Jones. 2, R. P. Wheadon. 3, L. C. C. R. Norris. Extra 3, Dr. J. Holmes. *vhc*, S. W. Thomas, R. P. Percival, Rev. T. C. Peake, R. A. Baker. *Light*,—*Cockerel*,—1, G. B. C. Breeze. 2, Miss Molineux. 3, Mrs. W. C. Drummond. *Pullet*,—1, Austen Bigg. 2, C. Graham. 3, Mrs. J. Turner. Extra 3, Philip Haines. *vhc*, S. Lucas, Austen Bigg, Alfred Webb. FRENCH.—*Any variety*,—*Cockerel*,—1, Robert Pound. 2, A. E. Ward. 3, W. H. Copplestone. *Pullet*,—1, Rev. Thomas Nolan. 2, Robert Pound. 3, Edward Taylor. *vhc*, W. Nicholls, John Porter, J. T. Calvert, Miss E. Williams, Mrs. David Lane. HAMBURGHS.—*Any variety*,—*Cockerel*,—1, George Randall. 2, C. F. Copeman. 3, G. Simpson. *vhc*, Messrs. A. E. & L. A. Pritchard, Thomas Lund. *Pullet*,—1 and Cup, T. Rynan. 2, George Randall. 3, Thomas Lund. DORKINGS.—*Any colour*,—*Cockerel and Pullet*,—1, W. Nicholls. 2, Butler Smith. 3, T. W. Jones. Extra 3, O. E. Cresswell. SPANISH.—*Cockerel and Pullet*,—Cup, Lady Allsop. 2, Jabez Walker. 3, J. Powell. *vhc*, John Aldridge. POLANDS.—*Any variety*,—*Cockerel and Pullet*,—1 and 3, Ben Rawsley. 2, G. W. Boothby. *vhc*, C. Bloodworth. LEGHORN.—*Cockerel and Pullet*,—1, G. M. Morecraft. 2, Rev. Grey Skipworth. 3, H. Moser. *vhc*, R. H. Foster. ANY OTHER VARIETY.—*Cockerel and Pullet*,—1, A. E. Ward. 2, J. Bishop. 3, Mrs. Muir. *vhc*, John Addicott. GAME BANTAM.—*Black or Brown Red*,—*Cockerel*,—1, Cup, and 2, E. Walton. 3, E. Morgan. *vhc*, H. Chard. *Pullet*,—1 and 2, E. Morgan. 3, E. Winwood. *vhc*, E. Walton. *Any other variety*,—*Cockerel*,—1, E. Walton. 2, C. H. Jeff. 3, Mr. G. Roberts. *vhc*, W. Hinton. *Pullet*,—1, J. Liveston. 2, C. Davenport Jones. 3, T. W. Adams. Extra 3, G. Roberts. *vhc*, E. Watson, E. Winward. BANTAM.—*Any other variety*,—*Cockerel*,—1 and *vhc*, M. Leno, jun. 2, E. Walton. 3, E. Pritchard. *Pullet*,—1, M. Leno, jun. 2, E. Walton. 3, Adam Clarke. *vhc*, Mrs. W. R. Hopkins, M. Leno, jun. SELLING CLASS.—1, J. Bishop. 2, H. Moser. 3, W. Weston. 4, Mr. G. Simpson. *vhc*, Mrs. Kettlewell, E. T. Gardom, J. S. Ham, Rev. T. C. Peake, H. Yardley.

PIGEONS.—CARRIERS.—*Cock or Hen*,—1, Cup, 2, and 3, John Baker. POUTERS.—*Cock or Hen*,—1 and 2, John Baker. 3 and *vhc*, A. Pratt. DRAGONS.—*Cock or Hen*,—1 and 2, Wallace Smith. 3, Ben Rawsley. Extra 3, H. F. Sparrow, John Baker. *vhc*, W. Britenden, James Lush, jun. BARBS.—*Cock or Hen*,—1, 2, and 3, John Baker. JACOBINS.—*Cock or Hen*,—1 and 3, Messrs. Wayman & Buchanan, 2, A. E. Gould. *vhc*, J. F. Harvey. TURBITS.—*Cock or Hen*,—Cup, John Baker. 2, O. E. Cresswell. 3, Thomas Holmes. *vhc*, Messrs. Heller & Wilkins, O. E. Cresswell. OWLS.—*Cock or Hen*,—1, Richard Woods. 2 and *vhc*, John Baker. 3, J. F. Harvey. TUMBLERS.—*Short-faced*,—*Cock or Hen*,—1, 2, and *vhc*, John Baker. 3, Henry Yardley. *Long-faced*,—*Cock or Hen*,—1, 2, and *vhc*, Richard Woods. 3, Ben Rawsley. FANTAILS.—*Cock or Hen*,—1 and 2, O. E. Cresswell. 3, John Baker. ANTWERPS.—*Long-faced*,—*Cock or Hen*,—1 and 2, Ben Rawsley. 3, S. Wade. *Short-faced*,—*Cock or Hen*,—1 and *vhc*, J. C. Waterhouse. 2, J. Baker. 3, H. Yardley. ANY OTHER VARIETY.—1 and 2, John Baker, 3, Arthur Allen. *vhc*, A. P. Maurice, Gerald S. Knott. SELLING CLASS.—*Cock or Hen*,—1, John Baker. 2, C. F. Herrieff. 3, Mrs. W. Riddell.

The Judges were for poultry Mr. E. Hutton; for Pigeons Mr. J. Hanley. The show of both seemed to us remarkably well judged.

TOY PIGEONS—THE TURBIT.

To my mind there is no more lovely and charming Pigeon than the Turbit. It is one of the long-established varieties which was described in the last century in a way that might now serve our purpose, but that the "fancy" has somewhat changed as to the Turbit's head properties, a point or shell being now considered almost indispensable, whereas formerly the plain round head was in vogue. Turbits are peculiarly Pigeons of the amateur; not that there is any want of fine specimens in the hands of dealers, but somehow this variety has long greatly flourished in the lots of several enthusiastic amateurs, who have for many years quite held their own against professional exhibitors in a way that has hardly been the case with any other variety. Clubs for the encouragement of particular varieties of poultry have of late come into fashion, and the fanciers of Turbits have been the first of the Pigeon amateurs to follow suit. The Turbit Club has drawn up a careful and elaborate standard of excellence, which (from such great authorities) does not seem to us always very explicit or intelligible to beginners. They are treading on dangerous ground, for, unfortunately, strong differences of opinion arise even between the brother fanciers of poultry and Pigeons. The question of the Jacobin's hood led to most acrimonious dissensions. Fortunately the Turbit's head properties have not aroused so much excitement; still its admirers have their differences, which must be considered when we come to look at the Turbit point by point.

The chief charm of the breed is the delicate softness of its plumage, and the pretty contrast between the colour of its shoulders and the white of the rest of its body. A flight of Turbits of mixed colours is a charming sight; there is no breed the colours of which have been raised to such perfection—rich jetty black, glowing red and yellow, soft blue, and still softer silver are among them. It seems as if the Turbits were the artist's ideal Pigeon, for in more than one famous picture of Venus we have seen blue Turbits as her attendant Doves. A neat little head, a dark intelligent eye, a proud yet in no way unnatural carriage, and a frill down the breast, in good specimens turning both ways, completes its contour. But as I have before said, the Pigeon critics are becoming very scientific, and I must in another article more minutely discuss the Turbit's points.—C.

HOW LONG CANARIES WILL LIVE.

It is surprising the number of years Canaries or Canary mules will live penned up in their little wiry abodes. Several instances have come to my knowledge of such birds attaining the age of from ten to twenty years; and it may be of interest to those who keep Canaries to peruse the remarks of a very old authority, who says—"As for the time that Canary birds live, I cannot ascertain it, for I may remark, that as they differ in constitution, it may thence

be concluded that they live longer or shorter according to the strength of such constitutions. But to be somewhat more particular; a cock Canary bird that is put up to breed every year seldom lives above ten years, and generally the seventh year is not fit to be put up to breed, for very often he will leave the hen to lay addled eggs. A hen that sits every year seldom goes beyond six or seven years, or if she does, it is because she has been well managed, or that she is of an extraordinary constitution. Of all sorts of Canary birds the grey live the longest, being much stronger than the lemon-coloured. A Canary of a strong constitution—one that has been well managed and never put to breeding—may live twenty-two years, but then he is subject to many diseases, as want of stomach, blindness, losing his claws and voice, and sometimes having the gout, and in that condition his languishing life, which threatens a speedy and certain death, is as troublesome to him, by reason of the sharp pains he continually endures, as a man's is to him when he has arrived at a certain uneasy degree of old age, at which the only sovereign remedy is no other than death."—GEO. J. BARNESBY.

VARIETIES.

THE MANGOLD WURTZEL MAGGOT.—A Lincolnshire correspondent, writing to us relative to the ravages of this maggot (*Anthomyia beta*), states that during July it made its appearance, and in about a fortnight the foliage of the plants appeared as if seared with a hot iron, and the crops appeared as if ruined. After the heavy rains, however, of August few insects could be seen, the plants put forth fresh leaves, and now the crops promise to be very good, although the roots are not so large as they would have been had they not been attacked so seriously early in the season.

— AGRICULTURAL PROSPECTS.—From our reports this week it appears that there is a considerable acreage of Barley yet to be harvested, and it is to be feared that the damage to this outstanding portion of the crop by the rains of the past fortnight has been very considerable. The Bean crop is to a great extent still in the fields, and for the most part will require considerable time for ingathering. The heavy rains have penetrated corn stacks that were left unthatched with a view to immediate thrashing, and as this has occurred on a rather extensive scale much of the excellent condition of the ingathered Wheat crop has thereby been lost. Thrashing operations have been suspended, and the ricks will now have to remain until their sweating is over. As the yield becomes better known its unfavourable character is spoken of in a very pronounced manner. Root crops are now known to be heavy, with the exception of Mangolds in a few districts; but this particular crop, though irregular, will probably turn off a good weight per acre. Grass has increased on the pastures, and cattle are doing well in most parts of the country. Losses are still reported amongst lambs, and there are well-founded apprehensions as to the soundness of flocks throughout the shires. The rains have facilitated the ploughing of stubbles but have somewhat hindered the working of fallows. As winter Tares are cheap a considerable average will probably be sown; in some cases they have been got in exceedingly well.—(*Mark Lane Express*.)

— BRAHMAS AND COCHINS AS MOTHERS.—Every poultry-keeper, says an American writer, who has had any experience worth mentioning, knows that the Brahmas and Cochins make the best mothers in the poultry kingdom. Of course a Brahma mother will not get up and fight friends, enemies, strangers, cats, dogs, and everything else that ventures within 40 rods of one of her chicks, as a Game mother will, but nobody wants one hen to do fighting enough for a regiment. The majority of poultry-keepers prefer hen mothers that are peaceable and can be approached with some degree of safety.

— THE SWAN.—Swans generally pair for life, their whole behaviour offering a beautiful example of conjugal fidelity. The two birds show the greatest affection for each other, always swimming in company, and caressing one another with their bills and necks in the most interesting manner; and should either be attacked the other will show fight in the most vigorous manner, though, of course, the male is the most powerful and courageous. Both birds help to prepare the nest, the male chiefly gathering the materials, while the female seems to take the chief part in the actual construction. A

swan's nest is an enormous affair, being built up of a large mass of coarse water plants as a foundation, which is lined with finer grasses. In this six to nine eggs are generally laid, which are, of course, very thick in the shell, and generally of a dirty white colour, sometimes dirty pale green. The time of incubation has been differently stated, but we believe Bechstein to be right in fixing it at thirty-five days, though some have said forty-two. The young when hatched are very thickly covered with down, and are generally taken to the water by the mother when only a day or two old. There they are watched over by both parents with the greatest care until grown enough to provide for themselves.—(From "*The Illustrated Book of Poultry*" for October.)

— MANURES AND PASTURES.—The *Agricultural Gazette* summarises the results of some experiments on the above subject as follows:—"Farmyard manure increased the bulk of the grasses, and in so doing diminished the weeds, with one or two exceptions. As a general principle, all manures tended to drive out the weeds by increasing the better herbage. Mineral manures alone diminished the proportion of the grasses by lending special aid to the growth of the leguminous plants, especially of the perennial Clover and the Meadow Vetchling. Ammonia salts, on the contrary, favoured the production of cereal grasses, increased their bulk, and by so doing almost destroyed as by a single blow the leguminous plants and the weeds. The hay crop was increased, but this occurred at the cost of several species which do not love ammonia salts; while at the same time—and this is worth noting—the ammonia dressing developed in a very remarkable degree the leaf of the grasses rather than the stems and seeds. Of the mixed manures, mineral manure and ammonia salts gave the greatest increase of crop, still favouring the graminaceous or grassy plants, almost to the exclusion of the Clovers and the leguminous plants. Weeds, with one or two exceptions, were driven off, and the development of the seed and stem of the grasses was particularly marked. It may here be mentioned with regard to the effect of sewage, that it increases the free-growing coarse grasses, such as *Poa trivialis*, *Triticum repens* or couch, *Lolium perenne*, and *Holcus lanatus*, and it follows of necessity that the weaker plants must be crowded out. When the bulk of a particular kind of herbage is increased, the number and proportion of the plants which had been the rivals of that herbage are certain to be diminished. The plants which receive the manures that favour their growth soon preponderate over those which are of lesser stature, and must necessarily be overcrowded. Ammoniacal manures increase the bulk of the grasses and thus crowd out the Clovers, while mineral manures alone increase the luxuriance of the Clovers and thus crowd out the grasses."

— SEED-SOWING MACHINE EXHIBITION IN ITALY.—An international exhibition of seed-sowing machines will be opened on October 20th at Pisa, Italy, under the direction of the Agrarian Committee, when prizes of gold and silver medals will be conferred by the Italian Minister of Agriculture for the best machines. The conditions with regard to exhibits may be obtained at the Italian Consulate, 31, Old Jewry, E.C.

NEW AND OLD PRACTICE IN BEE-KEEPING.—No. 2.

PEOPLE of every age have been attracted by the marvellous, and almost everybody is naturally desirous of novelty. Even in bee-keeping it is pleasant to indulge wonder—to venture on untrodden ground and make important discoveries. The cause of foul brood, we are told, has been discovered in Germany, and the discoverer has been noticed and rewarded by the Emperor.

The existence of the disease called "foul brood" was known in Great Britain a hundred years ago. In Scotland then it was called "backgone brood," and it has there borne that name ever since. What is meant by this name is, that some brood has died before it before reaching maturity, and has become foul. Ever since I can remember Scotch bee-keepers talked about backgone brood as a dreaded and destructive disease, one that is incurable and fatal in its effects. This has been my opinion all through life. The cause of this disease, we are told, is a fungus which attacks and destroys brood in the cell. The brood thus attacked bursts at a certain stage of development and becomes a putrid mass, hurtful to the health of hives and activity of the bees. A fuller and more lucid description of the cause of foul brood was given in the *Journal* some months ago, representing the German

discovery. Some weeks afterwards I read a quotation from a German report of a discussion on the question of foul brood. One statement of the report pleased me: it was to the effect that the gentleman who is looked upon as the discoverer said that the disease of foul brood is produced by many causes. In order to be brief I am making no quotations, but simply writing from memory.

Let us now notice the discovered cause of foul brood and call it a fungus, which spreads in hives and kills the brood. It has often been asserted that the honey of infected hives is affected and has power to transmit the disease to other hives; nay, that every bee that fills its bag from a diseased hive carries a bagful of poison; furthermore, that the very atmosphere surrounding a diseased hive is infected and carries the disease or plague to sound healthy hives by indraughts. Foul brood is an awful scourge in a hive, and if the above description be correct it is a scourge to be dreaded in every bee-keeping locality. I do not know enough either to confirm or contradict the account given of the nature of foul brood. I have never known the disease carried from one hive to another by indraughts, and often have I seen diseased hives closely surrounded by healthy hives. Last spring I smelt foul brood in a strong hive standing in the middle of my apiary. The hive was condemned at once, but execution was delayed, as we resolved to take a couple of swarms from it, but owing to the unfavourable season the bees were never fully mature for swarming; it was sent to the moors with the hope that they would gather some honey before the time of execution came. It yielded 20 lbs. of honey, and in the refuse combs foul brood was evident enough, but not very extensively spread.

As to the statements of the honey of diseased hives containing and carrying the infection, I have to say that they are exaggerations doubtless; for if such statements were correct where could clean and sound hives be found? Swarms from infected hives would carry the disease with them, and the distemper would soon fill every apiary and be universal. I have had many swarms from diseased hives, but the disease was left behind. Never once have I noticed the disease go with the swarm. Last year I noticed that an old stock hive was severely diseased in October. The bees were driven into a small hive and fed. It survived the winter, yielded a swarm, and is now a clean and healthy stock kept for another year.

Now a word or two about the remedy which has recently been recommended as effectual and able to remove the distemper from the apiaries of Great Britain. The remedy for foul brood we are told is salicylic acid applied by spray or sprinkling. Our friends will surely excuse me for here again expressing the opinion that foul brood is an incurable disease. Foul brood, as I understand it, is dead brood; these can never be restored to life or removed from the combs. That the spores of fungus may be destroyed by some application may be true. In such a case it would be prevention, not cure; and let me say that more evidence is required to make me believe that salicylic acid will prevent hives from being attacked and hurt by this terrible disease. A gentleman of considerable experience amongst bees knows that I think he is too easily influenced by novelties and statements made without proof, wrote to me the other week admitting in a modified sense the correctness of my opinion, stating that he had been misled in some things, one of which is the application of salicylic acid. In his hands it was a failure. The idea of preventing or curing foul brood by mixing this acid in their food does not, from my point of view, stand to reason. If the cause of the disease is a fungus and it spreads amongst the combs by spores, how can the food of bees affect it? The acid cure is new amongst us. I believe it will pass away and be forgotten, and the old remedy—if it is right to call it a remedy—will come to the front and gain the confidence of experienced bee-keepers. And what is the old remedy? The destruction of all diseased hives or combs. I heard the other day of an apiary extensively diseased, and that the owner had resolved to destroy the combs of all his hives and begin afresh with his bees and comb foundations. This is a wise and commendable resolution, the safest and best course he can pursue; and we have no doubt as to its success, for it never fails.

Now is a good time to examine hives for foul brood. If any cells are covered with concave or hollowed lids there is reason to fear. Such cells should be pierced and examined. If they contain foul matter let the bees be driven into an empty hive at the earliest convenience and fed into stocks. If the bees build combs to the extent of one-third of the hive only, the stock will be worth half a dozen of foul-broody hives for future work, and likely enough the value of the honey and wax in the foul hive will be greater than the cost of syrup used in feeding the bees. If foul brood be discovered in a hive in spring, say in March, the bees should be driven out at once and united to another hive. If not

discovered till near the swarming time, one or two swarms should be taken and the combs destroyed. I have already said that foul brood never loses its hold of hives; if not destroyed it will in time destroy them. Let me say in conclusion that the disease of foul brood will never become a plague in an apiary managed on sanitary conditions. It is hardly ever found amongst young combs, and if the combs never become old the disease can never extend far or do much harm. The most effectual way of preventing foul brood is to keep the bees in young sweet combs, and for honey and profit from bee-keeping young combs are better than old combs.—A. PETTIGREW.

REVIEW OF BOOK.

A Manual Rational of Bee-keeping, by G. DE RIBEAUCOURT.
Translated from the French by Arthur F. G. Leveson Gower.
London: David Bogue.

THIS little book is interesting, if only as furnishing us with some notion of what progressive bee-keeping has done for Switzerland, and how far the Swiss are either ahead, abreast, or behind the rest of the world.

It is curious, too, to find a work in the English language, and published in London (albeit only a translation), which absolutely ignores, because its author is evidently entirely unacquainted with English or American progress in bee-keeping. There is not the faintest allusion to any writer on bees, or to any system of managing bees outside the continent of Europe. We are, indeed, told in an "Appendix" that the Italian or Ligurian bee "has been introduced into Germany, France, and even into America," and there is similarly one solitary mention of England in connection with "nucleus boxes." That is all.

Altogether it is evident that bee-keeping in Switzerland is not "abreast" even of our experience in England or America—at least if M. Ribeaucourt is to be taken as representing the advanced knowledge and practice of his countrymen, and yet there is evidence of an awakening there. Our author advocates "rational bee-keeping," and he is quite on the road to the attainment of this object. For instance, we find him putting in the first place of improvement the use of moveable bars. The bar-frame is yet to come; but with moveable bars a great deal may be done in the profitable and "rational" management of bees, which is wholly out of the power of the "fixist." The author also gives preference to wood over straw as the material for the hive, which in so cold a country as Switzerland is a great testimony in favour of it. His hives, too, are larger than those in common use around him, although still far too small, for he only recommends a size of 13½ inches inside measurement by 6½ inches in height.

M. De Ribeaucourt does not contemplate even with his improved hive any extensive honey harvests, and yet we are persuaded that Switzerland might yield an enormous quantity of honey in good years high up or low down among its mountainous valleys. The common Swiss hive is here stated "not generally to contain more than from 15 to 18 lbs." It is, therefore, no bigger than our ordinary English skep; but our author seems satisfied with a winter store of about 25 lbs. in his stock hive, although he says he has sometimes placed supers over straw hives of the capacity of from 30 to 32 lbs. of honey, which have been filled in a fortnight or three weeks. It is evident that the honey harvests by the ewt. or more, which are frequent in America and not uncommon in England, are all but unknown in Switzerland.

The extractor is another improvement which our author mentions and recommends; that in use by himself is the invention of Schmiedl. It appears from the woodcut to be a much more clumsy affair than those which are now in use in England, but doubtless it answers its purpose sufficiently well.

There are sixteen chapters besides the appendix, which include everything important for the apiarian to know in order to the rational and profitable management of his bees. We may add that the appendix deals chiefly with the Italian or Ligurian bee, which our author very strongly recommends.—B. & W.

OUR LETTER BOX.

Growth of Fowls (A. F.).—The answer to all your questions must depend much on the condition in which birds are kept: thus a well-fed Dorking or Cochins will be full grown at eight months, but it will not be at its heaviest. A Spanish fowl takes rather longer. If in perfect health, and the weather be favourable, a fowl will moult thoroughly in two months. The older they are the longer the process. If a Cochins is to weigh 10 lbs. at maturity, we should be content to find him weighing 5 lbs. at four months, or even 4 lbs. A pound per month is good growth.

Worms for Poultry (N. R.).—The worms collected from ground, to the surface of which they had been driven by a solution of chloride of lime, may be given to poultry with perfect safety.

Golden Pheasants (Steward).—Golden Pheasants are not productive till they are two years old. It is after the same time the cocks get their plumage. Barley is the best food, but they are fond of and require green food. They must have clean water. They are very hardy, and require little or no shelter. They may be allowed to run about in all weathers. If the house is not already covered we advise you not to cover it. The birds do not require it, and any little gain by keeping out rain is more than counterbalanced by the loss of sun.

Mating Pigeons (A Constant Reader).—The influence of a cock Pigeon does not continue with a hen during the winter. We believe there is no fear of your Antwerp hens next year showing any taint from the Archangel and Trumpeter cocks; at least, such has been our experience after breeding Pigeons of many kinds for twenty-five years.

Large Hives of Bees (Derby).—Last year it is no wonder your bees did nothing. This year seems to have been nearly as bad in the midland counties across England. Probably they began the year, as many of ours did, in a very enfeebled condition, and it took them a long time to recover. We advise you to stick to your large hives, and not give way to discouragement. Yet, if you can afford it, we should recommend you to add a couple of stocks to your apiary this autumn, taking care to have them really good. They will travel well in October, and may be had cheaper than in spring. Feed them a little (those you now have) to quicken them during warm weather this month.

Killing Bees (O. F. W.).—The old practice of killing bees with brimstone is exploded, and we cannot advocate its adoption. Honey is now taken from the bees by driving them into another hive. Smoke from fustian rags is blown into the hive to partially stupefy the bees, the hive is then placed on its crown (upside down), an empty hive is placed on it month to month, wrapping a tablecloth tightly round the junctions to keep the bees in, then the bottom hive is drummed with both hands or two pieces of wood for fifteen or twenty minutes, and the bees ascend into the empty hive; the honey is thus obtained, and the bees preserved for future work after being fed with syrup during the winter. The present is the time for honey-taking.

REMARKS.

19th.—Fine in early morning, rain from 9 A.M. till noon; afternoon and evening fine, bright, and breezy.
20th.—Very fine, clear, cool day, with bright sunshine.
21st.—Dull, cold, misty day; slight rain all the forenoon and dark; clearer with glimpse of sunshine at 4 P.M.; foggy damp evening.
22nd.—Dull in early morning; fine, bright, much warmer day.
23rd.—Early part of morning dull and overcast; very fine, bright, pleasant day; evening close and overcast.
24th.—Thick white mist in early morning, hazy and dull generally, slight sunshine 2 P.M. till 3 P.M.; clear fine evening.
25th.—Fine pleasant day, but rather cloudy the after part.
Slightly cooler and much drier than the two previous weeks.—G. J. SYMONS.

COVENT GARDEN MARKET.—SEPTEMBER 29.

WE have little alteration to quote this week, trade being dull and prices hardly maintained. Several samples of American Apples have reached us, making their full value. Kent Cobs quiet.

VIOLAS.

IF you wish to have your flower garden always gay at a trifling cost—if you wish a bright companion for your chaste Snowdrops when the early spring sun glints on their snowy bells, or a lake of Tyrian purple in which to float the gorgeous scarlet of your Geraniums and Verbenas under glowing midsummer skies, or a soft carpet of divers colours at the feet of your lordly Gladioli in autumn—if you wish to have a flower which in heat or cold, in storm or sunshine, in wet or drought, will be always bright and sweet—then let me recommend you to invest in a collection of Violas. They will not cost you much; a few shillings will stock a small garden, and a few pounds will plant a domain. The price of one of Mr. Kelway's choice Gladiolus corms, or the cost of a single Orchid, will give you a supply of flowers nearly all the year round in every shade of colour from purest white to deepest indigo—marvellous shades of blue, and lilac, and purple, and crimson, and gold, which exist in no other border flower in such profusion and perfection.

Violas had but a small beginning, but they are steadily progressing towards greatness, and bid fair to become general favourites, and an indispensable adjunct to every well-managed and attractive garden. But to have Violas always except in the very depth of winter, and to have them in perfection, we need a knowledge of their ways and requirements, for, like every other plant, they gratefully repay you for good and loving cultivation, and pine and dwindle away if neglected. Now, I love Violas; I have hundreds, yes, thousands of them, and having grown and cultivated them for many years, will tell you all I know about them. Perhaps someone who would like to grow them, or someone who has tried and failed, will haply light on these lines in our Journal and exclaim with satisfaction, "Why, this is the very thing I want!" I hope it may be so.

Well, then, to begin. You would like some, of course, as early as possible in the spring, dotted in and out it may be among your Snowdrops and Crocuses, or your fancy may lead you to give them a bed to themselves. At all events it is now September, and by the time this is printed it will be October. Do not lose any time, but get your bed ready. Do not let it be in a shady place at this time of year, they like the spring sun and care not for frosts. Work it up fine and "plumb" as we say in Devonshire, and put in plenty of good manure half decomposed. I am a great advocate for soot and a little lime in addition, because slugs and wireworms are terrible enemies of Violas when young, and they have a special objection to

both the above manures. If your soil is a rather heavy loam so much the better; mine is very heavy, and yet they grow like weeds. Buy your young plants as soon as you can. Rooted cuttings at this season are to be purchased at a cheap rate, and there is nothing better for present planting. When you receive them, if they come by post as they generally do, place them in water for a few hours until quite revived, and then, if possible, pot each separately in a small pot in sandy soil, and keep them in a rather close shaded frame until they appear to be growing, when more air and light may be given, and at the end of a fortnight or three weeks they may be planted out in their permanent quarters. You can if you like put them out at once after standing them in water for a few hours, but some will then probably fail, and by the other method every plant will grow and establish itself strongly before winter. These are the plants that will bloom earliest in spring and onward until July, when they will have seen their best days, and if left to themselves will grow shabby. But to keep up a continuous supply of flowers I like to make two plantings—one in October to come in with the spring bedding plants, and another in February for the summer garden. They should not be planted out for a bedding display later than the end of February, as they do not take hold of the soil sufficiently after that to make luxuriant growth.

As for the earliest blooming plants, cut them down when they have lost their freshness, and they will soon throw up a fresh supply of young flowering shoots, some of which you had better use for cuttings, taking them out of the heart of the plants with a sharp twitch, when you will probably find them come up with a few small roots attached. These strike almost anywhere and at any time except in winter. I have them in all sorts of corners and places; in the sun or in the shade, it does not seem to matter, they all grow, and having plenty of young plants they can be used as wanted. This is the secret of success—keep up a supply of youngsters to take the place of the old plants, and you will always have flowers.

Now as to the best varieties. The best Whites are Mrs. Henry Pease, Crystal Palace, Pilrig Park, and Vestal, the latter rather creamy. Best Yellows—Sovereign, Golden Gem, Golden Perpetual, Brilliant, and Grievei. Best Blues and Lilacs of various shades—Amabilis, Bluebell (small), Admiration, Acme, Freedom, Waverley, and Holyrood. Maroons and Crimson—Forerunner, Mulberry, and Attraction. There are a multitude of others, and I hear that Messrs. Downie & Laird of Edinburgh are offering some new varieties, said to be a great advance on the older sorts. But all are lovely, and I am sure that if you follow my advice you will succeed in adding a new charm to your garden, and have reason to thank—R. W. BEACHEY.

SUMMER AND AUTUMN PEARS.

As the planting season is approaching it will not be inopportune to direct attention to some evidence that was published in our columns at the end of 1879 and beginning of the present year, on the merits of several varieties of Pears for summer and early autumn use. With the object of concentrating attention on this subject we published a series of portraits of good Pears, and the qualities of some of the best-known varieties were duly discussed. Figures of some of the later Pears will follow in due course, and in the meantime it will be well to summarise as briefly as possible the opinions of

cultivators on the varieties that were referred to in the discussion.

First, as to the earliest or summer Pears that ripen in July or early August according to seasons and districts. There are but few of these, only the following being named:—Amiré Joannet or Harvest Pear, Petit Muscat or Small Cluster Pear, Doyenné d'Été or Summer Doyenné, and the Green Chisel. Of these the Petit Muscat and Green Chisel were only mentioned once each by two cultivators, and the weight of evidence was overwhelmingly in favour of Doyenné d'Été and the Harvest Pear, the former for growing as pyramids on the Quince for affording early dessert fruit, the latter as standards on the Pear for yielding larger quantities of juicy Pears for ordinary family use and market purposes. These Pears, especially the former, soon go "sleepy," and it is seldom more than from one to three trees are required. They are useful and should be planted in the open, as wall space can be better employed by other varieties.

Succeeding the above, the following late summer and early autumn Pears were named:—Jargonelle, Williams' Bon Chrétien, Citron des Carmes, Clapp's Favourite, Beurré Giffard, Beurré de l'Assomption, Ambrosia, Early Bergamot, Desirée Cornelis, Madame Treyve, and Souvenir du Congrès.

Jargonelle and Williams' Bon Chrétien were regarded as indispensable, as they were found to succeed in all soils where Pears will grow, and in all districts. Both of them bear early on the Quince, but make finer and fruitful trees on the Pear stock. They are adapted for the north aspect of walls in the south and midlands, and for standards and espaliers almost anywhere except in the extreme north and very cold localities, where they require the shelter of walls; indeed, a tree of each is worthy of a good aspect on a wall in any garden where space can be found for the production of early and fine fruit. It may be said that of all the Pears mentioned in the discussion none met such wide and general approval as Williams' Bon Chrétien. It was elicited that a Mr. Stair (not Wheeler as was generally supposed), a schoolmaster at Aldermaston in Berkshire, was the raiser of this popular Pear, which is known in the locality as "Stair's Pear."

Citron des Carmes was described by many as a useful Pear, especially as a standard for orchards, but in some very strong soils and cold districts the fruit often cracked more or less seriously. It is, no doubt, a serviceable Pear for the purpose indicated, but possesses neither the good appearance nor high quality of some other varieties; still a tree or two should be included in most collections.

Clapp's Favourite was very highly spoken of by Mr. Abbey, who described it as much more tempting than Jargonelle, possessing all its qualities with the addition of a musky aroma, the tree being grown on a Pear stock, and favoured with a south-west aspect in a high and exposed site in Yorkshire. This is undoubtedly a very excellent Pear, and will in all probability become more extensively cultivated as its merits become better known.

Ambrosia is considered by Mr. Lumsden of Bloxholm, a gardener of great experience and sound judgment, as the "best autumn Pear." Grown as an espalier in a walled garden in Lincolnshire the fruit ripens before Williams' Bon Chrétien. It is a great bearer and of excellent musky flavour. It is a round medium-sized fruit of delicious quality, but does not keep long after it is gathered. An espalier pyramid or a standard may well be grown where space can be afforded.

Beurré Giffard did not meet with anything like unanimous approval; while it was favourably spoken of by some cultivators as a good grower, free bearer, and of acceptable quality, by others its aromatic flavour was not liked, "WILTSHIRE RECTOR" for instance, an undoubtedly good judge of Pears, never being able to eat more than half a fruit at a time of this variety. It was further elicited that it has another drawback—namely, early, very early flowering, and the blossoms, except in favourable seasons and localities, being liable to injury or destruction by frost. It is quite distinct in flavour, and those who like highly perfumed Pears should grow this variety.

Beurré de l'Assomption was described by those who have grown it as a Pear of first-rate quality and handsome in

appearance. It is the largest of all the early Pears, but to have it exceptionally fine it should be grown in a good position against a wall, of which it is worthy. It grows well on both the Pear and Quince stocks, on the latter making a good pyramid, in which form, and in a good position, fruit of the highest quality is produced, but not nearly of such fine appearance as that produced by a wall tree. It may here be mentioned that many, probably the majority, of early Pears are of better quality when grown in the open than against walls, which suggests that wall space should as much as possible be devoted to later varieties, or to a tree or two of such of the earlies which are desired to yield fruit as early as possible and of the first size and appearance.

Souvenir du Congrès, like the preceding, has not been extensively fruited. All who have grown it describe it as a very large and handsome Pear and of excellent quality, yet in the latter respect not quite equalling its prototype Williams' Bon Chrétien. It is not spoken of as a free bearer, but, on the contrary, is stated by some cultivators to be rather shy. It is a very imposing fruit, fine for exhibition, and makes a handsome and good dish. To have fine fruit the tree must have the assistance of a wall. The general opinion, so far as it has found expression, of this Pear is that it is larger, later, but not better than Williams' Bon Chrétien.

Desirée Cornelis, although it does not appear to be largely grown, has been accorded the high approval that it merits as a delicious summer dessert Pear. The tree is a good grower and bearer, and makes a handsome pyramid on the Quince. Grown against a wall the fruit is larger but not better, and there is no doubt whatever that this Pear would succeed well as a standard in favourable districts, and in some form or other it is certainly well worthy of cultivation.

Madame Treyve does not appear to be so extensively grown as its merits deserve. Those who have had experience with it speak in high approval of its quality, and it is undoubtedly a very fine Pear of the first quality. In most localities it requires the aid of a wall, which it well deserves, to produce fruit in fine condition. This is a Pear that those who do not possess it may safely add to their collections.

As successional varieties to those above mentioned the following Pears have been submitted for consideration, and most of them have been figured and incidentally alluded to by correspondents:—Summer Beurré d'Arenberg, Hessele, Suffolk Thorn, Beurré Superfin, Beurré Hardy, Comte de Lamy, Emile d'Heyst, Doyenné du Comice, Flemish Beauty, Bonne d'Ezée (syn. Brockworth Park), Fondante d'Automne, Louise Bonne of Jersey, Maréchal de Cour, Marie Louise, Marie Louise d'Ueele, and Pitmaston Duehess; and further particulars from various districts of these or any other Pears ripening during October and November would be opportune and instructive.

THE GLADIOLUS.

RIPENING THE CORMS—DISEASE—CULTURE.

I FIND the present time of year the most critical in the management of this noble plant, the ripening or non-ripening of the corms having a great effect not only on the succeeding season's flowering but on the health of the plants. A few remarks on how I treat these may therefore be useful. We have all heard of the Gladiolus disease, and some of us have had practical experience of it, how the young plants turn yellow and sickly, and in most cases dwindle away and die before the summer is far advanced. Notwithstanding the very bad seasons we have lately experienced I have not seen the disease for at least three years, and, strange as it may appear, it was a bad season that led me to the means of successfully treating the disease. One of these bad seasons which set in a few years back gave us at lifting time a lot of small unripened corms; these were well attended to the following year, and instead of allowing them to ripen, the whole stock was lifted with balls of soil attached, some being placed in pots and others planted in inside borders. I have ever since lifted the corms and ripened them off indoors and with the most satisfactory results. This year the plants are in robust health, and have been flowering since the end of July.

Though this has been an extra fine season the young corms received a check through the severe drought, and are only now making up for time previously lost. Though some of the stock is ripening in the ground I shall lift most of them and ripen them

off under glass. The corms are not expected to be large this year, but that is not a matter of much importance. I keep the stock in a perfectly cool room, the corms being laid out singly on shelves, there they remain until growth commences in spring. Varieties such as Colbert and Shakespeare start before the others, and some growers advise planting at different periods, commencing as early as February with the first batch. I do not find this necessary to insure an early bloom, as, like Potatoes, some varieties arrive at maturity much quicker than others, and very early planting causes them to make a dwindly growth, consequently I do not think it advisable to plant before April. I have in previous years set out our stock in clumps in borders. In addition to the usual winter double digging and dunging given to the borders for other occupants, soil was taken out in spring where the *Gladiolus* clumps were to be planted, and about a barrowful of fresh loam, dung, and soot was placed in each hole, mixing the natural soil slightly with it. From six to twelve corms were planted in each hole so prepared. This is a plan I can recommend to growers of small quantities as yielding excellent results with little labour. Our collection is getting somewhat large now, and I grow them in lines in a prepared piece of ground, but it is possible the clumping system may be reverted to.

In preparing for growing them in masses in lines or beds the ground is trenched about 2 feet deep, turning over the bottom of the trench and adding dung; 4 to 6 inches of dung ought to be worked in whilst the trenching proceeds—I prefer a mixture of manure from the stables and cow houses. Fresh soil added to the bed is always beneficial. Before the time for planting out arrives a dressing of a couple of inches in depth of old Mushroom bed manure should be worked in to the depth of 7 or 9 inches, mixing the manure well in. This dressing is of great benefit to the plants in the earlier stages of growth. Draw the rows 15 inches apart and deep enough to allow a layer of coarse sand, and the corms to be 4 to 5 inches below the surface when covered. As growth progresses a surfacing of horse droppings which have been prepared by heating in heaps will be of much advantage.

The way I have supported our plants this season was by placing strong stakes 20 feet apart in the rows and running a strong string from stake to stake about 2 feet above the ground level. The spikes were then securely tied to the string. I found this a neat and effective mode of support, and that it took very much shorter time than it would to put single stakes to each plant.

Growers for exhibition generally give quantities of liquid manure to their plants. I am very doubtful if it is necessary; it certainly is hurtful to the stock. Our plants were only watered once about the end of August, and very many spikes were produced with from ten to thirteen flowers open at one time and fresh. Dewy nights and warm days is the weather which produces the finest spikes. A newspaper fixed like one of the caps common on the 5th of November on each spike as the first flowers open, gives sufficient shelter to those intended for exhibition. Spikes at their best may also be kept for a few days in a cool cellar; they can also be forwarded by cutting and placing in bottles of water in a hothouse. Those which have only three blooms open can be expanded in a cool room, but the individual flowers are not so fine in this case. Some of the old varieties are still the best, such as Shakespeare, Madame Desportes, Madame Basseville, Meyerbeer, and Octavie hold their own against most of the newer varieties. "D., Deal," is still working amongst the *Gladiolus*. We will doubtless hear what his experience has been with them, and the varieties he considers best in time for buyers.

—R. P. BROTHERSTON.

VEGETABLES IN 1880.—No 2.

TOMATOES.

No vegetable ever became so rapidly popular in our gardens and markets as the Tomato. True, it is not a new introduction; but until very recently it was only cultivated by a few, and growing it for market was hardly ever thought of. Now the demand for Tomatoes is not confined to large towns, or their cultivation to large gardens. A few years ago all the varieties in cultivation might have been counted on the fingers of one hand, but now they are nearly as numerous as of Melons or Potatoes. There is hardly a gardener who has grown them for a year or two but now grows one of his own "raising" or "improving," and many nurserymen give long lists of Tomato names. After trying a score or more "varieties" and "selections" I have come to the conclusion that good varieties might still be counted on the fingers, and for ordinary cultivation and general supply a few really good varieties will prove more satisfactory than a large and mixed collection.

Trophy, in its original form, is still one of the best. It grows robustly, fruits freely, is of good shape, attains a large size, and

possesses fine flavour. Criterion is another fine easily-managed variety, and so is Carter's Greengage. The former is a very deep salmon colour; the latter is bright yellow, and for flavour unequalled. These three most distinct and meritorious varieties should be grown by all who cultivate Tomatoes. Stamfordian is, according to my experience of it, straggling in growth, shy in setting, and very uncertain in fruiting—that is, the fruit does not come in clusters like the others, and those which do swell have become all shapes and forms. Some are of fine shape and splendid size for exhibition purposes, but except for this it will not repay the grower. Nesbit's New Victoria and all those of the "Cherry" section are very ornamental and useful where Tomatoes are valued for dessert; but for general or extensive kitchen use they cannot be recommended. Large Red, a very free-fruited sort, is too much furrowed to commend itself. America appears to be the head quarters of the Tomato family, and I have more faith in good varieties coming from there than this country. A new one introduced from there this spring by Mr. Gilbert of Burghley, and named "Paragon," does credit to its name, as it seems likely to be one of the finest Tomatoes in cultivation. I have numerous fruits of it at the present time ripe against the open wall, and some which I cut measured 18 inches in circumference and weighed about 1 lb. each.

Anyone with a good Melon pit may easily have Tomatoes all the year round, and those with no glass at all may have them on the open wall from the beginning of August for the next four or five months, as the supply of ripe fruit can be extended by cutting all the green fruit before the frost injures them, and hanging it up in a dry room to ripen gradually. I have had plants fruit very well as standards grown here and there on a border and trained up a stake, but growing them against the south aspect of a dwelling house, glass house or wall is the surest place for them doing well. Good soil at the root and a restricted top growth produces good results; when allowed to run wild they are useless. Some of my plants growing underneath standard wall trees are little more than a yard high with a single stem, and they are bearing as many as thirty-four good-sized fruits. To secure early crops the best way to grow the plants is in pots. Seed sown in January will soon germinate in a gentle heat, and the young plants produced being potted on as they become ready until they are in 8-inch and 10-inch pots will bear ripe fruit in April. They should be grown in a compost of two parts loam and one of decayed manure. Early in the season they must be placed in an unshaded position, and all superfluous growths be removed as they are formed; other batches may follow in pots throughout the whole season, as this is an easy and profitable way of growing them at all times. My plants in pots are generally placed in corners about the houses where no other plant would pay for attention. Much fruit has been gathered this season again from plants in pots along the back wall of a lean-to vinery. Those with plenty of other means to grow them may laugh at placing them in such a position, but where houses are limited and it is desired to make as much of every corner as possible the plan will amply repay a fair trial.

Where fruit is grown for everyday kitchen use it is necessary to try and have one lot succeeding another in a small continuous quantity; but when they are grown to preserve, excepting what is wanted occasionally for immediate use, one large quantity at any time will answer the purpose, and these may be gathered from out of doors if grown to come in about the present time. Working on this plan the earliest fruit will be had from plants in pots; that for preserving from the open air, and the later supplies must also be had from indoors. These may also be grown in pots like the earliest, as they are always handy in them to shift from a cool to a warm corner as the weather may dictate; but where an ordinary good Melon or Cucumber house exists they will do here better than anywhere else. They should be planted out in the bed like Cucumbers and trained thinly over the wires. Many do not cultivate Cucumbers after this time. Let them clear them out now, and if they have any Tomatoes in pots plant them in their place. Large Tomato plants may be transplanted in this way, and old plants if becoming exhausted in pots when planted out soon make fresh growth, and are far better for winter fruiting than tender young plants. I do not think this plan is often tried, but it deserves to be. Any temperature between 40° and 60° will answer in winter. Watering must be done carefully, and moisture should not be overabundant in the atmosphere.

KIDNEY BEANS.

Like Tomatoes these have been much finer out of doors than last year. Then Dwarf Beans did fairly well, but Runners were nearly a failure. This season both have been most abundant. As a Runner Carter's Champion has done remarkably well, the blossom not dropping much without forming pods, as is frequently the case; and the pods, besides being abundant, become of large size

and fine colour. Canadian Wonder is still a good Bean amongst dwarf varieties, and Osborn's for forcing; but the latter will meet with a strong rival in Carters' new Haricot Bean, which grows about the same height as Osborn's, but is more prolific and fruits earlier, which is a very great recommendation, as we cannot have a French Bean to fruit too soon after sowing the seed either indoors or out. Suttons' Giant White Runner is another variety deserving of notice and cultivation, as its fine pods are extremely good in flavour. Kidney Bean seed was the worst I had in the past spring, as it appeared to have been ill-matured and in many instances failed to grow: but I hope for better results next year.—J. MUIR, *Margam*.

HEDYCHUM GARDNERIANUM.

A REFERENCE to Hedychiums in your answers to correspondents last week reminds me of a magnificent batch of *H. Gardnerianum* that I saw lately in the conservatory at Buxted Park. Mr. Prinsep has planted it in one of the beds, and it has spread and become a thicket of wonderfully robust stems from 6 to 8 feet high, most of them with flower spikes quite a foot in length and nearly as much in diameter. The effect of these huge spikes of bright yellow flowers with their long scarlet stamens is very striking, and they present a very attractive appearance, to which the elegant Canna-like foliage materially contributes. Hedychiums are classed with stove herbaceous perennials, so are Cannas. Why should not both prove suitable for the flower garden in summer? It is worth a trial, for no clump of Cannas that I have seen, even at Battersea Park, is worthy of comparison with the grand bed of Gardner's Hedychium at Buxted.—SUSSEX.

VINES AT GARSTON.

LIKE your correspondent "J. U. S.," I have recently visited the "Vineyard," and send a short supplementary note to his concise description on page 305.

Grapes are grown in seven large houses, but those that attract most attention are the Madresfield Court Vine and the Vine of Gros Guillaume, which are grown on the extension system. The former is planted in a large house facing due east; it was planted in the centre of the house, and its roots were formerly inside. But two or three years ago an outside border was made, thus giving the roots a chance of spreading as well as the top growth. The branches are trained horizontally right and left and have filled the house. They are now extending a good distance into a second house 40 feet long that had been previously filled with Peach trees. This Vine annually produces heavy crops of first-rate Grapes. Under Mr. Cowan's system of management the berries never crack, and this he attributes to diminishing the supply of water after colouring commences. This is really a grand Grape, and for market purposes cannot well be surpassed. The Gros Guillaume Vine also fills a half-span house 40 to 50 feet in length, and is extending into an adjoining span-roofed house, which is to be entirely filled with it. This Vine is planted at one end of the house, the roots being entirely inside, and the rods are trained lengthways along the roof. It never fails to bear a good crop of Grapes. At the time of my visit some very large bunches fully 18 inches in length were hanging upon the young wood, yet the Vine is furnished with good-sized bunches from the oldest portion of the rods. A glance at this Vine, however, will be sufficient to indicate to a practical observer that the long-spur system, or the retention of a good portion of young wood annually, is the system pruning to pursue with this variety.

Vines in pots are grown to the extent of seven or eight thousand, including fruiting and planting canes. Of the former about five thousand are grown, and that they will fruit freely there is no doubt from the extra care that is exercised in thoroughly ripening them. Mr. Cowan does not believe in cut-backs, and has not more than thirty in his establishment. The Vines are grown from eyes into a fruiting size in one season, and are remarkably strong with plump eyes so much desired by Vine-growers. A good quantity of the parings of horses' hoofs are incorporated with the soil used for them, and two or three top-dressings of a similar compost to that in which they are potted is given during the season. Two or three low houses are devoted to the Vine eyes in the early season, and the eyes are inserted in beds of soil instead of small pots as usually practised, and when large enough are placed in 6 and 7-inch pots. The young Vines are all pinched when about 9 inches in length, and the lateral growths removed, so that the Vines have to start again from the main bud. Mr. Cowan contends, by pinching the young Vines it gives them an opportunity to make roots for a time instead of exhausting themselves by making a thin wiry growth, and that they are strengthened considerably at the bottom—much more so than if not stopped,

as they start away again after stopping with greater luxuriance. This is by no means a general practice, yet the result is all that can be desired, and the Vines are worth a long journey to see. I am informed from a most reliable authority that they are better this year than they have ever been since the Vineyard has been established.

Roses and all kinds of flowering and fine-foliaged decorative plants are also extensively and well grown in this nursery.—W. BARDNEY.

FUNGI A CAUSE OF DISEASE IN PLANTS.

PRESUMING that Mr. Luckhurst as a reasonable man is desirous of discovering the truth, and that he does not write merely to support an opinion whether it is well or ill founded, I will briefly review what he has regarded as favouring his view of the subject. The first statement was a general and positive one—that attributing disease in plants to the effect of fungi "is in every instance erroneous." Only three instances were selected to prove this comprehensive declaration, and one of these scarcely required the trouble taken to disprove it, as it was the unsupported opinion of one individual. The other two, however, were worthy of consideration, as different views have been taken of them, and the defenders of each have adduced many facts to substantiate what they regard as correct. Had Mr. Luckhurst succeeded in demonstrating that the opinions respecting the Potato disease and Peach blister opposed to his own were incorrect, he would still be far short of proving his original statement; but even in these instances he has not advanced sufficient to convince the fungologists, as he terms them, among whom I suppose he includes myself.

In the first place, treating of the Potato disease, your correspondent considers that the tissue of the plant must be diseased before the fungus can grow upon it, because he tells us the "plague spots" invariably appear before the fungus is perceptible. This is quite contrary to my experience, and in reply to a question Mr. Luckhurst gives the modified explanation that he has "never been able to detect it [the fungus] till after the disease has laid hold of the foliage." Now this is decidedly ambiguous, for the instant the mycelium has penetrated the tissue of the leaf the substance is discoloured, and the ordinary first indications of the disease appear, so that it would not be likely that the fungus could be detected before the "plague spots" are seen, as these are the discolorations produced by the poisonous action of the mycelium. As to hot dry weather checking the progress of the disease and wet weather favouring it there can be no doubt, but that only more clearly indicates the fungoid origin of the disease, and scarcely agrees with the attempted explanation that "the gradual drying-up of the tissue renders it susceptible to the attacks of the disease." Mr. Luckhurst has carefully avoided the question about the first appearance of the disease in this country—namely, why the fungus *Peronospora infestans* was unknown here before 1845; and I might further ask why that disease, if not the result of the fungus attacks, should have appeared so suddenly, and so widely and seriously affected the Potato crops?

Respecting the Peach blister Mr. Luckhurst presents us with very clear statements, which in regard to the facts I have no doubt are quite correct; but though I am "open to conviction" I am not prepared to give my full credence to the conclusions. "It is," says he, "positive assurance that enables me to say that the blister is caused by cold wind and nothing else." I have been under the impression that cold exposed positions favour the growth of the fungus, because I have repeatedly observed the blister very prevalent under such conditions. But that is not all. For several years in a garden not fifty miles from the one under Mr. Luckhurst's charge, a number of young Peach trees planted against the southern aspect of the north wall in the kitchen garden were annually severely affected by the blister; yet the position was an exceptionally sheltered one, for the garden was protected to the north and east by a hill of considerable height, and the walls both east, west, and south were sufficiently high to effectually prevent any injury from winds, which could not in this case have produced the blister. Can Mr. Luckhurst explain this, or the case described by Mr. Taylor on page 487, vol. xxxviii., when trees from a house were placed outside and were yet unaffected with blister, though those previously out were greatly injured by it? It is obvious from both these facts that the very positive statement as to the wind alone invariably causing blister is not correct; and he has not ventured on an explanation of how wind could produce such effects, nor does he give an example of similar injury being done to other trees.

That there is an analogy between plants and animals I have not disputed, only that it is not sufficient to justify the argument drawn from the supposed fact that weak human beings are more subject to infectious diseases than those in robust health, for it is

indeed "such a mode of argument that serves rather to confuse than enlighten."—S.

OLD CUCUMBER PLANTS.

ABOUT this time Cucumbers which have been grown in houses during the summer generally show signs of decaying. The leaves assume a yellow hue, the fruit ceases swelling, and the conclusion arrived at as a rule is, that the plants are "quite done" and may be thrown away. This may be the best mode of dealing with them in some cases, but not in all. When the main stems are good the old plants may often be started into growth again, to do as well or better for the next four months than young plants.

We have still the same plants bearing now as we had in the month of February last, and they have lately been dressed to yield a supply all the year round, or nearly so. When planted they were only expected to supply fruit until the end of July. Then they were in such healthy condition that a little more feeding and heat induced them to produce a large number of fine fruits, and now after the soil has been thoroughly top-dressed they are making clean fresh shoots and forming many healthy fruits, which will equal or surpass those from the young autumn plants for the next two months or more. Probably all varieties might not do so well, but Telegraph, our main variety, prospers with the treatment. Those of your readers thinking of throwing away old plants might do worse than give this mode of renewing them a trial.—A KITCHEN GARDENER.

MICHAELMAS DAISIES.—No. 1.

AUTUMN imparts to gardens an aspect of dreariness that is all the more noticeable and unpleasant immediately after the brightness of summer. The glowing colours of Pelargoniums and similar bedding plants, with the more varied and softer tints that mark the majority of hardy herbaceous plants, seem to vanish together, and in a week or two the beds that have so delighted us only possess masses of fast-decaying vegetation. In many gardens, from the fading of the summer flowering plants to the advent of the Chrysanthemums, there is comparatively little to please or enliven. Why is this? There is certainly no necessity for gardens to be so utterly destitute of flowers as they too often are during the dull months of October and November, for there are several genera of plants that contain late-flowering and attractive species well fitted to supply this demand. Among these few surpass in numbers and beauty the Michaelmas Daisies; and being of free growth, thriving in any ordinary soil, easily increased, and requiring but little attention, they unite those very useful qualities of ornamental appearance and easy culture. This specially applies to about a dozen forms out of the twenty or thirty autumn-flowering Asters in cultivation; but there are some which, from their straggling habit, diminutive and dull-coloured flower heads, are by no means sufficiently attractive to be worth growing. The select forms are, however, varied in habit, size, and colour of the flower heads. Some do not exceed a foot in height, others rise above 6 feet; some are compact and bushy, others are loose and straggling. The colours are white, lilac, blue, purple, and rose of diverse shades, and the capitula range in size between a sixpence and a crown piece. The mode in which the flower heads are borne also constitutes another distinction—namely, some are arranged in a dense corymbose inflorescence, others are loosely spread in a raceme like or paniculate manner, while a few have the heads borne singly. It will thus be seen that there is a greater diversity among Michaelmas Daisies than is commonly supposed; and whether they are employed for planting with shrubs or in the ordinary mixed border, they will amply repay their cultivator for the space they occupy and the little trouble bestowed upon them by bearing a profusion of flowers at a period when the supply from other sources is fast diminishing.

As to the relative merits of the species and varieties opinions would probably differ in some degree, but in the selection which follows those only are recommended that possess characters of sterling value, regard being paid to habit and general effectiveness of the flowers. It may, however, be well to remark first that the chief beauty of colour and form of the capitula is in the outer or ray florets, for the centre florets are yellow in nearly all the species. As the former, therefore, vary in size so we have a large or small flower head; the closeness or looseness of the arrangement and the neatness of the outline also constituting additional degrees of merit.

Aster Amellus.—This species has been in cultivation in English gardens for nearly three hundred years, as that assiduous plant grower Gerard had it in 1596; and in his interesting "Herball" he describes it under the name of *Aster Italicum* or the "Italian Starwort," as bearing "faire blewish floures, yellow in

their middles, and shaped like Marigolds, and almost of the same bignesse, whence some have called them Blew Marigolds." It has also some still more ancient historical interest, for it is famed to be the *Amellus* mentioned by Virgil. Referring to this Phillip Miller states, in his "Gardeners' Dictionary," that *Aster Amellus* abounds in the "valleys of Italy, Sicily, and Barbonne, and the leaves and stalks being rough and bitter the cattle seldom browse upon them, so that they remain in the pasture after the grass is eaten bare, and, making a fine appearance when they are full of flowers, might well engage the attention of the poet." The plant is moderately compact in habit, numerous stems rising from the

Fig. 60.—*Aster novæ-angliæ* var. *pulchellus*.

root to the height of 2 or 3 feet, bearing somewhat spathulate leaves at the lower portion, which become narrower higher on the stem. The flower heads (capitula) are about $1\frac{1}{2}$ inch in diameter, with narrow purple florets. A Russian variety of this species named *bessarabicus* is also grown; it chiefly differs from the type in the slightly larger and paler flower heads. Both these produce their flowers during September and October.

A. novæ-angliæ.—North America is the great home of the genus *Aster*, and of the numerous forms from the western continent *A. novæ-angliæ* is one of the best. This, too, is an old and well-known inhabitant of our gardens, its introduction dating as far back as 1710. The typical form is of strong growth, frequently exceeding 6 feet in height, but is not so straggling in habit as some of the tall species. The leaves are narrow and bright green, the capitula being neatly formed and of a fine purple tint. This

with the varieties mentioned below often flowers very late, especially in cold positions; but this is rather a disadvantage than otherwise, as frost is frequently severe enough to spoil its appearance before the flowers are fully developed. To avoid this evil a moderately sheltered position should be selected for it. The variety *roseus* has large flower heads, extremely regular in outline and of a bright rosy tint, very attractive and useful. Another variety is appropriately named *pulchellus*; it is not quite so tall as the type, and bears fine terminal flower heads with bright yellow central and rich purplish blue ray florets. It is a handsome variety and deserves the attention of all who desire to obtain a really attractive plant for their gardens, the flowers also proving very useful for cutting.—L. C.

[The accompanying engraving represents a seedling *Aster* which appeared in Mr. Lee's garden at Clevedon, and it seems to be an improved form of *A. novæ-angliæ pulchellus*, partaking of the colour that distinguishes the variety *roseus*. The flower heads are of good size and circular in outline, the rosy purple ray florets being closely set round the bright yellow centre. The increased size of the flower heads, the brighter colour, and the rather better form, are almost sufficient to entitle it to a distinct varietal name.]

OLD v. GILBERT'S VICTORY OF BATH MELON.

FOR the information of a writer in this Journal of September 23rd (see page 292), who says he does not know what difference there is between the old and Gilbert's Victory of Bath, I beg to inform him that they are two quite distinct varieties, and anyone who has grown Gilbert's Victory cannot mistake it for the old Victory. Why Mr. Gilbert should have named his new Melon Victory of Bath I cannot understand, as it has no resemblance whatever to the old variety of that name. I have grown the old Victory of Bath for more than twenty years; it is an excellent Melon, oval in shape, slightly netted, and its flesh is of a dark green colour. When well grown it has few equals in its class. I have grown Gilbert's Victory since it was sent out two seasons ago. I had the seeds direct from Mr. Gilbert, so there can be no mistake about it being the true variety. It is a round fruit of medium size, very slightly netted with me as a rule, but I have had odd fruits well netted, but not generally so; flesh white, and when ripe the skin is of a light yellowish colour. It is quite distinct from any other variety that I have grown.—A. PETTIGREW, *Cardiff Castle*.

A WEEK IN YORKSHIRE.—No. 3.

OAKWORTH HOUSE.

(Concluded from page 260.)

A LITTLE more remains to be said on Mr. Holden's garden to enable its character and completeness to be comprehended by your readers. A great deal might be said were anything like a detailed description attempted of the various structures and their contents, for there are some forty houses in the block, the majority of them being of large size. As only a rapid walk was taken through this maze of glass, so the reference to it must be of a general rather than a particular character.

The houses are entered from the picturesque balcony of the winter garden, the ends of some of the structures constituting the boundary of that remarkable edifice. In the centre is a span-roofed Muscat range, large and lofty, with a lantern roof. There are both outside and inside borders, and heat is afforded by twelve rows of 4-inch pipes. The Vines are covering the roof and bearing an excellent and uniform crop of capital Grapes. At the end a lean-to branches right and left, with which is connected other houses—one, a Fig house, is filled with splendid trees planted in an inside border; another, a Peach house, but in which the trees do not prove satisfactory in such a lofty house, which is better adapted for Vines than Peaches. From here we enter a very long Orchid corridor with plants one side and *Nepenthes* on the roof, the other side affording access to several other houses—*Fuchsia* house, *Azalea* and *Heath* house, which contain many healthy specimens, very large stoves filled with a great assortment of healthy plants, and on to the vinery block. There are seven vineries, some being parallel with each other, and it will be necessary to make some provision against the roots from one border crossing to the other, which would be extremely inconvenient in case of any of the Vines required lifting, which they are certain to do at some time or other. A trench down the centre between the two borders and cement walls would answer the purpose. The Vines are generally in admirable condition throughout and bearing heavily, Mr. Holden requiring a great supply of fruit for his many friends. In one house is an excellent crop of *Lady Downe's*, and the best

crop of *Waltham Seedling* I have ever seen. When in superior condition this Grape has an imposing appearance, and well ripened is of good quality. The roofs of the houses are supported by pillars, to which Tomatoes are trained on each side of the path. In other houses *Mrs. Pince*, *Gros Colman*, *Golden Queen*, and *Alicante* are doing equally well, the bunches being both large and numerous and the berries good. Some of the Vines, as in other places, lost their foliage prematurely last autumn by sudden and severe frosts occurring, and this defoliation has impaired the value of the crops. The early vinery is a lengthy lean-to, and the *Black Hamburgh* crops had been cut for some time previously to my visit. All the houses are well, even prodigally, heated, and great judgment is requisite in regard to moisture and ventilation in these large and essentially dry structures.

Passing higher we arrive at another large block of houses—four lean-to's and fourteen span-roofs, the ends of the latter opening into corridors about 10 feet wide and 160 feet long. These houses are devoted to Pines, Cucumbers, Melons, and small plants for decorative purposes, the roof of one of the lean-to's being covered in every part with Tomatoes trained to wires like Cucumbers. The crop was a prodigious one, and the thousands of large scarlet fruit had a rich effect. Hot-water pipes are plentifully, almost too plentifully, provided in all these houses for both top and bottom heat, the mains passing under the paths in the front corridor. All the paths are of cement, but the water standing on those in the plant houses incommodes visitors. The walks were therefore given another covering of cement and made slightly convex, and now, as far as regards the welfare of the plants, &c., there is a deficiency of atmospheric moisture.

At the back of the vineries is a range of offices 200 feet long, tool sheds, seed and store rooms, and with a spacious Mushroom house, all efficiently heated. Below the ground level is the boiler house, a huge excavation, lofty and roomy, in which the huge boilers are set that heat the several structures. Somewhere about 4 miles of piping are heated from these boilers, the remaining portion, $1\frac{1}{2}$ mile, being heated from the stoker of the winter garden. Mr. Shaw speaks highly of Weeks's tubular boiler for quick action and great power. All the smoke is conducted into a massive shaft in the rear of the buildings. Owing to the different levels and the arrangement of the houses there is quite a network of pipes, with valves innumerable, and it must be a work of time for a stranger to understand them and their workings; indeed, Mr. Shaw observes that had he not been employed as an under gardener when the work of erection was in progress, he must have experienced great difficulty in comprehending their complexity now.

All throughout the establishment good management, order, and excellent culture prevail; nothing appears to be neglected, nothing out of place—a result that certainly could not be achieved without the exercise of much forethought, great attention, and persevering industry, both on the part of the head and under gardeners, the former working with an object in view, and that is the very commendable one of endeavouring to the utmost of his power to have all things done well.

Behind the large field of glass referred to and higher up the hill is the kitchen garden, but at this altitude the crops are all late—early Peas only ready in August, and Dwarf Kidney Beans can only be depended on grown under glass. Westward is the pleasure grounds, a broad undulated lawn with belts of shrubs and a few flower beds, this reaching to and merging into a plantation which is the northern boundary of Mr. Holden's pleasure grounds.

In the front of the mansion, and across the road that separates it from the dale below, is another pleasure ground with lawns, water, raised shrub banks, and flowers, Pansies being quite at home, bright and cheerful. In close proximity are large and massive schools for the village and district, and in the rear of them Mr. Holden's stables, all very substantial, neat in design, and ornamental.

Altogether Oakworth House and its appurtenances is a wonderful place, made and owned by a wonderful man, who has graced his name deeply in the tablets of history, and by his mechanical skill, labour, and perseverance has at the same time benefited the nation and enriched himself. It is such men who have made England great by extending her commerce, and it is of such men that the nation is justly proud. Had I seen no other garden during my short tour I should have been well satisfied with my "week in Yorkshire" by having been accorded the privilege of inspecting the home and gardens of Isaac Holden.—A RAMBLER.

ANEMONE JAPONICA.—To enjoy the full beauty of both the pink and white forms of this valuable autumn flower we must have old-established plants growing in tolerably deep rich soil. I have a lot of clumps of both just now in full beauty; they are

upwards of 2 feet high, not with a loose and straggling air, but with clustering heads of flowers that are especially effective amidst the decay of so many summer plants.—L. O.

THE LATE MR. ARTHUR VEITCH.

WILL you kindly permit me, through the medium of your columns, to pay a grateful and sincere tribute to the memory of one who has, I deeply regret to hear, lately closed an honourable and useful career? Of the general business qualifications of the deceased gentleman it would be presumption on my part to speak. But as one who has experienced at his hand the utmost kindness and consideration in one particular branch of his business—namely, the dealing with men who seek the assistance of the firm in obtaining situations, I would fain say a few words. Doubtless there are hundreds of men who, like myself, will remember with thankful and grateful feelings the kindness they experienced from him under these circumstances. No matter how urgent other business might be, time was always found for attention to their claims, and they were always met in a kindly and congenial spirit. Many a gardener who entered his presence with head bowed and heart heavy, retired from it—solely by the influence of his cheering and kindly manner—in a better and happier frame of mind. I feel sure had this alone been the claim to grateful remembrance, his useful life had established on the horticultural world the name of Arthur Veitch would be long, lovingly, and gratefully remembered, and his early death sincerely deplored.—A. EAMES, *Heanton Satchville, Beaford, Devon.*

LAWN MOWERS.

I DARESAY many who are interested enough in mowing machines and read this short article will be surprised to see my signature attached to it, but the fact is I have been away from home since the end of June, and I have scarcely seen any flowers. In Scotland, with the exception of the famous *Tropæolum* with its lovely scarlet flowers, I saw nothing to interest me. The hotel gardens as a rule were filled with annuals and weeds, and I saw no flowers to make notes of. Here in Yorkshire I have not come across anything which I can possibly write upon, and so I am driven to the somewhat uncongenial subject of lawn mowers.

There are a great number of these, and in this letter I shall carefully abstain from causing offence to any one firm. I shall mention no maker's name, in order that I may not only avoid the charge of puffing any particular firm, but also to avoid injuring others whose machines may be equally good or even superior, although unknown to so humble an individual as myself. I shall therefore confine myself to a few hints as to the means whereby to keep the mowers in good working order, and also how those who may be without one, or dissatisfied with that they have, may know what new one to order. The most important part of the machine is the neck, in which the spindle or shaft of the knives revolves. In some of the older machines it was the practice of the makers to put a solid piece of iron with a hole bored in it wherewith to form the neck. I should strongly recommend all persons to abstain from buying a machine made in this way, because the dust and grit soon wears the hole larger and the spindle smaller, so that the latter shakes loose, and it is impossible to set the knives as required. It is now the custom to have a couple of brasses fitted into the framework, and as the hole wears these can be filed easily where they join, and by means of adjusting screws they can be set so as to fit closely round the spindle.

The distance of the knives from the cutting plate is next to be considered. The makers, I believe, tell you to set the knives so closely as to be able to cut thin paper when turning them round with the hand. The course, however, I pursue is to set them so as to just touch the plate all along. It is the practice of some gardeners when they find the machine very hard to push, to screw the knives back slightly from the plate, under the supposition that it will be easier to work thereby. This is a great mistake, as the grass wraps round the edge of the plate and is torn off the roots, and not cut as it ought to be, thereby forming a kind of brake, against which the knives have to rub at every revolution, and requiring necessarily increased efforts to push the machine along. The same result is produced when necks or brasses are worn. After setting the knives (I am speaking of a brand new machine which comes properly fixed from the maker), screw the brasses close up round the spindle—not so tight, however, as to "bind" it, but just so that you can shake very slightly the spindle in the necks. Next adjust the front rollers on wheels, so as to regulate the closeness you wish the grass cut. Each gardener will have his own views on this point. The closer the grass is cut, however, the harder will be the work, and *vice versa*. For

my own part I put the machine on to a stone step and adjust the rollers so that I can push the end of my forefinger under the bottom plate—that is, from one-quarter to three-eighths of an inch.

That is pretty nearly all that requires to be seen to in order to preserve the machine in good working condition. I take it for granted that it has been oiled before anyone commences to use it. The necks of the knife spindle will require oiling several times a day, owing to the speed at which they revolve. The other bearings will only need it once a day. If the cog wheels become clogged with grass or soil they should be cleaned or scraped with a pointed piece of iron, and an occasional general cleaning will be advantageous. If the grass wraps round the edge of the cutting plate, as alluded to above, the machine is not doing its work properly, and nothing blunts the knives sooner. These should be screwed close to the plate. It is, I believe, argued that there is less friction with a chain than with cog wheels. This, however, I consider altogether fallacious, as every inch of the chain has a pivot, and the dust, grass, and dirt which collects in the chain in my opinion causes far more friction than the cog wheels. There is also another reason—the pivots wear, and this lengthens the chain and requires the cog wheels on which it works to be moved back, and when further worn the chain does not fit on to the cogs but mounts on the top of them. When this happens a new chain must be procured. Again, in mowing slopes the chain is apt to slip off.

If I am asked what size of machines I recommend to be purchased, I reply that I find it difficult to answer, for so much depends upon how close and how often you mow the grass. If a boy can be obtained to pull the machine in front, I should recommend a 16-inch cutter; if a man alone is to work it, then a 12-inch is the best size. A man and boy twelve years old will do as much with one machine as two men will with a machine each. The number of knives in each mower varies considerably in different makes. Some have eight, revolving slowly as compared with others; some have three, and one, I believe, only two. My opinion is the fewer knives the better, if only they revolve sufficiently quickly. Thus the spindle holding two knives should make four times as many revolutions as that containing eight in passing over any given distance. I consider that the grass is cut more easily with a quick than with a slow travelling knife, particularly when the grass is long. How amusing it is for anyone who knows anything about lawn mowers to read the advertisement that so often appears, "will cut long or short grass, wet or dry, &c." Now it is possible when the machine is new and in tiptop condition to do this, but when the first keen sharpness is worn off will it do so? As to long grass, decidedly no; as to wet grass, not satisfactorily, for the machine becomes clogged in all directions, the grass cannot fly into the box, but drops back into the knives. The word "box" reminds me that the question may be asked, Do you advise using one or not? My answer is, As a rule certainly use one, and for this reason: first, if there be any Daisies in flower and the decapitated heads be left on the ground, you will have a bountiful crop of them next year; and secondly, if wet or damp and the machine delivers the grass in front, you will have your machine clogged, and you will continue to chop the same grass over and over again. When, however, the grass is dry and short, and there are no Daisies, you may take off the box, and you will find the mower run more easily.

Before concluding I would advise all those whose machines are out of order not to consider that it is the fault of the particular make, and so cast it aside for a different machine at a cost of some pounds; but, on the contrary, let them see if by adopting these few hints, which I have endeavoured to make as plain as possible, they cannot make their old servant do its work properly.—WYLD SAVAGE.

THE STAPLEFORD ROSES.

"D., Deal," on page 299 condemns these Roses in strong terms, but he does not say what is amiss with them, except that he has not seen many at the shows. There is time enough for that yet; but Rose-growers are not all exhibitors—only a fraction of them indeed, and it struck the writer that the Stapleford Roses would form a very valuable addition to our Rose gardens. To talk of any new plant "collapsing" almost as soon as the stock has left the hands of the trade is rather premature. May I ask "D., Deal," to tell us if the said Roses refuse to grow or to flower, or if, in fact, the descriptions given of them by several writers, including Mr. Bennet, are incorrect? Your correspondent says, "If there are any who have found these Roses different to what I and all those with whom I have spoken with have, I hope they will make their opinions known;" but he has forgotten to specify their faults himself. As a set-off against the remark of the "head of a

well-known London firm" the present writer was told by another well-known "head" that he considered these Roses a valuable addition; "but," said he, "Mr. Bennet has stolen a march on some of our Rose-growers, and his Roses are viewed with some hostility by them."—WILD ROSE.

GRIZZLY BOURJASSOTTE FIG.

THIS is the most delicious of Figs, and it has well maintained its high character this year. A small tree trained upon a south wall had a full crop of fruit, almost as abundant as the Brown Turkey, and infinitely superior to it in flavour. The fruit is handsome, of medium size, of a curious colour which I see is termed chocolate in the "Fruit Manual," very soft and apt to shrivel slightly, but not to crack as it ripens. It is so rich as almost to clog the palate with its sweetness, and in this respect surpasses every other Fig I have tasted. The tree is moderately vigorous, somewhat apt to lose a few inches of the tips of the leading shoots by frost, but in other respects it is quite hardy.—EDWARD LUCKHURST.

THE following letter has been sent to us for publication by "AN ARTIST"—"Under the heading of 'OUR ILLUSTRATIONS,' I observe that the *Gardeners' Chronicle* of the 23rd ult. delivered a brief lecture on journalistic honour, in which it was distinctly implied, if not actually stated, that you had mutilated the block of *Rubus rosaeifolius* var. *coronarius* that had been supplied to you from Messrs. Veitch & Sons. I wish to point out, not only that this was a most unjust accusation, but that the directors of your contemporary had the means of knowing it was so, as the engraving had appeared in precisely the same condition some time before you published it: that charge therefore fails totally. On the question of borrowing and lending blocks, let us see how rigidly the Editors of the *Gardeners' Chronicle* have adhered to the honourable rule of acknowledging the favours of those to whom they are indebted. From the beginning of last June to the present time at least twelve large borrowed nurserymen's blocks have appeared in the *Chronicle*, five of which are not acknowledged and two are wrongly named. On June the 12th, 1880, page 745, Mr. Bull's block of *Dieffenbachia regina* appears under the name of *Dracaena regina* without the slightest acknowledgment of indebtedness to the lender. On June the 19th, 1880, pages 776, 777, and 781 are three borrowed blocks of *Cypripediums*, one being wrongly named. Two of these blocks are acknowledged as if the other was the *Chronicle's* own property, whereas all three were Messrs. Veitch's property. On July 10th, 1880, pages 40-41 are illustrations of four of Mr. B. S. Williams's new *Nepenthes* on two blocks. The descriptive matter is taken from Mr. Williams's catalogue, but there is not a word to the effect that the blocks were borrowed. Also on August 28th, 1880, page 278, is an illustration of some new *Coleuses* which are stated to represent some of Mr. Bull's varieties, but there is no mention that the block was Mr. Bull's too. If you refer to the numbers quoted you will find that what I have stated is correct, and the *Chronicle's* future complaints on a subject of this nature can have no weight whatever."

[It is not our custom to search for faults and inconsistencies in the columns of our contemporaries, as errors from various causes are liable to creep into all journals; but in this instance we have verified our correspondent's statements, and under the peculiar circumstances of the case we feel justified in publishing his letter.—EDS.]

— A GOOD deal has been written on the SHANKING OF GRAPES lately, and various theories have been advanced respecting

the cause of the evil. Deficient root-action, overcropping, hard forcing, and a fungus attack have all had their advocates. There is, however, a case of Grape-shanking at Chiswick that does not appear to be directly traceable to any of those causes, yet, notwithstanding, one or more of them may exist even if they are not plainly visible. This instance of shanking is in the middle of as grand a house of young Vines as is probably to be seen in England. The wood is as stout, strong, and apparently as satisfactory as can be desired; the foliage is of remarkable texture, as thick as the thickest Fig leaves that were ever grown; the crop is light—from two to four bunches on a Vine strong enough to bear three times the quantity. The varieties are Gros Colman and Alicante. Only about the centre of a house 200 feet long are there any signs of shanking, and the berries in the house are generally magnificent in size and colour. There is apparently no debility here, no excessive luxuriance, no forcing, and apparently no lack of root-action; yet the Grapes on a few of the Vines shank. Who can explain this? Does the fungus theory apply?

— A KIRKCUDBRIGHT correspondent of the "Entomologist" referring to WASPS *v.* SCALE ON FRUIT TREES, states that even the oldest inhabitant cannot remember such swarms of wasps as have been observed this season. In one instance he counted along an avenue of 300 yards nearly seventy nests, and in the woods it was scarcely safe to quit the trodden paths. But as a set-off, he remarks that the wasps have helped to clear the fruit trees of "mussel scale," and he considers that they have destroyed quantities of aphides and many flies.

— "W. K." WRITES—"In the Begonia House at Kew may now be seen some fine plants of *BREDIA HIRSUTA*. The plants are about a foot high and nearly as much in diameter, grown in 48-size pots. The flowers are light rose, contrasting admirably with the dark brown foliage. It occurred to me at the time I saw it that it would make a very desirable plant for decorative purposes. This appears to be one of the many *Melastomaceous* plants that is much neglected at the present day. By its free flowering qualities and robust growth, one would be inclined to imagine that under liberal treatment it would well repay all trouble bestowed upon it."

— *Nature* states that "Mr. McGibbon, who has been many years Superintendent of the BOTANIC GARDEN, CAPE TOWN, SOUTH AFRICA, retires on a pension of £150 a year. A movement is on foot to remove the Gardens from their present contracted site in Cape Town itself, and to create in the neighbourhood of the city a botanical establishment more worthy of the seat of South African Government. As a first step the appointment of Director has been offered to the well-known Cape botanist, Professor MacOwen of Gill College, Somerset East. It is, however, doubtful whether the state of his health will allow of his undertaking it."

— A CORRESPONDENT, referring to the value of AUTUMN-SOWN SWEET PEAS, strongly advises everybody to sow a row or two during the present month. They are not hurt by frost, and the early blossoms are much valued as cut flowers. If possible sow one row near a south wall to accelerate growth in spring, and thereby gain a week in the opening of the flowers.

— "No one" writes an "OLD GROWER," "can visit Messrs. Veitch's nursery without observing the value of SMALL POTS FOR ORCHIDS. The growth of *Dendrobiums* is wonderful. One plant of *D. nobile*, growing in an ordinary 6-inch flower pot saucer half filled with crocks, has produced thirty growths this year, some of them 2 feet in length and all exceptionally vigorous. *Phalænopsis Schilleriana*, *amabilis*, and others are similarly luxuriant both in very small pots and saucers. A great number of Orchids are undeniably overpotted and consequently unhealthy, and a removal

from large into small pots would effect a great improvement in the condition of many plants that are not thriving satisfactorily."

— REFERRING to the statement which we republished from the *Irish Farmers' Gazette*, that a LORD PALMERSTON PEACH had been gathered 11 inches in circumference, and weighing 17 ozs., Mr. F. Prothero of Malpas Gardens, St. Thomas, Exeter, informs us that he has gathered a fruit of this variety 11 $\frac{3}{4}$ inches in circumference, and it only weighed 13 ozs. He has also grown fruit of Lady Palmerston 10 $\frac{1}{4}$ inches in circumference, the trees of both varieties being grown against a wall in the open air.

— MR. WM. SUTHERLAND, late manager to Messrs. R. P. Ker & Sons, Aigburth Nurseries, and to Messrs. Ireland and Thomson, Craigleith Nurseries, Edinburgh, has been appointed manager to Mr. J. Cowan, The Garston Vineyard, Liverpool.

— WE learn from the *Banffshire Journal* that Mr. STEPHEN OSBORN, late gardener and bailiff to the Earl of Effingham, Tusmore, Bicester, has been appointed gardener and bailiff to the Earl of Fife, Upper Sheen House, Mortlake, Surrey.

— AN attractive herbaceous plant that still continues flowering in the borders is CUPHEA SILENIOIDES VAR. ZAMPARI. It is 3 or 4 feet in height, and bears the large rich purple peculiarly formed flowers near the upper portion of the branches. This is the best of the varieties of Cuphea silenoides in showiness, and succeeds admirably in any light rich soil, the flowers being produced throughout the greater part of the summer and autumn.

— WE are requested to state that "THE AMIES CHEMICAL MANURE COMPANY" have removed from No. 79, Mark Lane, to more extensive and convenient offices at No. 75, Mark Lane, London, E.C.

— WE learn from the *Gardeners' Magazine* that 178 varieties of Potatoes were represented at the recent INTERNATIONAL POTATO SHOW. The number of dishes staged of the chief exhibition varieties were as follow:—Magnum Bonum, 143; Schoolmaster, 108; International, 94; Grampian, 85; Vicar of Lalcham, 71; Snowflake, 60; Trophy, 58; Porter's Excelsior, 56; Woodstock Kidney, 55; Triumph, 51; Blanchard, 43; Red Emperor, 40; Manhattan, 35; Early Rose, 30; Covent Garden Perfection, 27; Early Vermont, 26; Climax, 25; Pride of America, 24; Brownell's Superior, 23; Rector of Woodstock, 21; Bresec's Peerless and Breadfruit, 20 each; Bountiful and Pride of Ontario, 18 each; Late Rose, Wonderful, and Mammoth Pearl, 17 each. The following well-known and useful varieties were represented by a few dishes—namely, York Regent, 2; Myatt's Prolific Ashleaf, 15; Victoria, 5; White Don, 1; and Lapstone, 7; while 57 varieties were represented by single dishes only.

— THE Irish print which we were obliged to take to task a fortnight ago for PRESS PIRACY, has confessed its fault, tendered its "most ample apology" to its copier, and thereupon, as might be expected, it sets to roundly abusing us, who are the only sufferers from its misconduct. The Editor of the print in question is an old offender, and we presume the consciousness of the fact vexes him. Last December the following paragraph appeared in the "Gardener":—

"We would recommend the Irish 'Gardeners' Record' to the attentive perusal of the horticultural press generally—it is worth watching. It is difficult to feel anything but commiseration and sympathy for a journal that has to pack its pages promiscuously with paragraphs about such subjects as 'Holloway's Pills,' which the 'Record' states, 'are as mild as they are efficacious.' This statement is not given as an advertisement, and so we expect its Editor has tried them. There is no harm, of course, in a grateful acknowledgment of this kind; but it is different when the 'Record' appropriates whole chapters from its contemporaries without acknowledgment, simply because it appreciates them as it does the pills. We observe that it has transferred that chapter of the 'Squire's Gardener's' on 'Mixed Flower-Gardening,' from 'The Gardener' to its own pages without as much as 'By'r leave, sir.' Robbing the ample stores of 'The Gardener' is perhaps not so heinous an offence; but what is anyone to think of the same paper abstracting matter in the same

way from the pages of its humble contemporary 'The Villa Gardener?' In the same number of the 'Record' is an unacknowledged article on 'Epidendrums,' which appeared in the 'V. G.' of August last. There are also articles on one or two other subjects we should like to know the parentage of."

Again in February of the present year it was observed in the same paper—

"Since we recommended the Irish 'Gardeners' Record' to the attentive perusal of the horticultural press, that paper has been wonderfully profuse in its acknowledgments of its sources of information, and its contents now show to what extent such prints are indebted to their contemporaries for their matter, one might almost say for their existence. The horticultural portion of the 'Record' consists of about nine pages of large type, and that space in the number before us contains no fewer than twelve borrowed articles and extracts, and these, it need hardly be said, form the pith of the paper."

WINDOW GARDENING.

AT page 305 "B. T." reminds us that the season for damping-off is at hand, and gives some advice as to saving Primulas from its effects. That his plan is effectual I readily admit, but it is possible that some who cannot carry out his instructions may grow Primulas as well as those who do, and that simply by the exercise of additional discretion and care at critical moments, thereby saving a goodly item in expenditure. There has been unfortunately of late too much credit given for results without regarding the costs. I know that in the horticultural world it is difficult to judge how much credit actually belongs to a man, how much to natural and other advantages, and how much to accident. But gardeners themselves ought to be able to judge of their own achievements in an unbiased way. I believe many of the best of them do this, and that although outsiders and employers may praise and even flatter, there is a meek inward feeling that the result, brilliant as it may be, is not worth the cost.

To have Primulas 18 inches across in February or March after growing them all winter in a temperature of 50° to 55° may be creditable, but it is nothing extraordinary, as I have many of this season's plants as large as that already, which have been simply grown in cold frames, and which would in a cottage window or an airy greenhouse flower through the greater part of the autumn and winter. Let it be understood that I do not want to boast of my own doings—indeed they are not mine, for I have never either potted or watered one of the plants—and would prefer not mentioning them except for the sake of illustration, not to disparage the achievements of "B. T.," which may be much more creditable than I imagine; but I want to see the growing of such simple and beautiful flowers as Primulas, Begonias, and Cyclamens become more popular and take the place to a certain extent of the Pelargoniums one everywhere sees in the cottage windows. I ought not to say much against Pelargoniums, as the cottages in this neighbourhood are greatly enlivened by their presence, and they make a gorgeous display for the benefit of the passer-by. But what about the background? It is simple ugliness itself, and to produce it the inmates consent to sit in semi-darkness.

There are many plants of easy growth which are naturally of symmetrical habit, such as the three I have mentioned among flowering plants, and Ferns, Palms, Dracenas, and Ficus elastica among foliage plants, to which may be added others which, if not quite symmetrical, have at least some beauty on both sides, as Richardia aethiopica and Vallota purpurea. Two or three of any of these plants will furnish a window without obstructing more light than a narrow blind, for which generally they may be substituted, and will give pleasure both to the traveller and the resident. Once let the cottagers know that the most beautiful of Tuberous Begonias may be easily had flowering in their windows through the summer, and that one of the best of all winter flowers, the Cyclamen, will take the same position in winter, I should expect to see a rapid change in window gardening. I advise, then, that when there is a choice of doing the same thing by extra care as by spending a comparatively large amount of money, we should to a great extent recommend the former method, for care begets love.—WM. TAYLOR.

HEAVILY CROPPED VINES.

ONE of the greatest and most common mistakes made in Grape-growing, and which has often been commented on in this Journal, is overcropping. This heavy cropping, however, may under certain conditions be repeated with impunity, as some of the most heavily cropped Vines that I have yet seen, and which I have every reason to believe have been equally as heavily cropped in previous years—and still remain vigorous—are those in two fine span-roofed houses at The Deodars, Meopham, Kent. Mr. Phillips,

the practical gardener in charge, evidently, however, knows what he is about, being well aware that the Vines could not long stand such a heavy strain upon their resources without extraordinary compensation being given at the roots.

The borders are inside of the house, and are composed almost entirely of strong loam, and to these are given liberal top-dressings of strong unexhausted manure, and frequent heavy waterings varied with strong liquid manure, the latter not merely during the times the fruit is being perfected, but after it is all cut, as at this time the root-action is still going briskly on, and the Vines are thus enabled to feed on and to assimilate the rich supplies of food frequently placed at their disposal. It is this knowledge of their recuperative power that justifies Mr. Phillips in thus heavily cropping his Vines; and there is no reason why others may not also crop their Vines heavily, provided they are well established and receive similarly liberal treatment.

My advice—far from being original—to all, whether their Vines have been heavily or lightly cropped, is to give them abundance of moisture at the roots after the fruit is cut till the foliage has changed; varied, in the case of heavily cropped Vines, with strong liquid manure. This has the effect of “plumping” up the buds, and also insures a good start being made the following season. Of course, where the borders are outside, in most instances the autumn rains will be found sufficient. It is the inside borders that are most frequently neglected after the fruit is cut.—W. IGGULDEN.

PELLIONIA DAVEAUANA.

ON visiting Kew a few days since I was much struck with the beauty of this plant. It is a native of Cochin China, and by its pendant habit is admirably adapted for basket work for the greenhouse. The leaves much resemble *Tradescantia zebrina* in shape, but are much more handsome. The centre of the leaves is light green, with a broad band round the margin of dark brown or chocolate. At first sight it would easily be mistaken for one of the fine-foliaged *Begonias*, but it is quite distinct from that genus. It is growing in a shallow pan suspended from the roof, and judging by appearance the treatment it receives seems to suit it well.—W. K.

IRISES.—No. 12.

STILL continuing the consideration of the great Apogon division of Irises we come to the three remaining groups, one of which only contains a single species, and the others are not large, but they comprise some of the most beautiful and most interesting of all the beardless forms. Here it may be remarked that it is one of the very agreeable peculiarities of this genus that large numbers of the species are individually marked by such qualities of beauty that all comparative terms of excellence are useless, as each one seems in itself to stand unrivalled. Some particular gracefulness of form or striking combination of tints characterises all the most noteworthy forms. The groups now to be described are chiefly distinguished by the possession of ensiform leaves, and in addition certain minor peculiarities of the perianth aid in the classification of the species. The first group consists of a single dwarf species with sword-shaped leaves named *I. maculata*; it is not marked by any special excellence, and is, I believe, not in cultivation at present. Then follow the two groups of caulescent forms—one with very small inner perianth divisions, and the other with falls and standards spreading, and in some instances nearly of equal size. The most attractive of the species included in these two sections I will now refer to without following the precise order of their arrangement.

By far the most interesting, historically at least, is the native species *I. Pseud-acorus*, the yellow Iris or Fleur de Luce, of which so much has been written. This is one of the only two forms found wild in the British Islands, and is distinguished by its large yellow flowers and its frequenting the margins of lakes or similar moist localities. When growing luxuriantly, as it does in a suitable position, and bearing the fine yellow flowers in abundance, its beauty is of no mean order, and in many gardens it forms, where judiciously employed, a beautiful margin to artificial lakes. Gerarde wrote concerning it in his quaint manner—“The yellow Flag prospereth well in moist meadows, and in the borders of rivers, ponds, and standing lakes; and although it be a water plant of Nature, yet being planted in gardens it prospereth well.” It must have been the remembrance of some happy spot where it was in its best condition that prompted Charlotte Smith to write—

“Amid its waving swords, in flaming gold
The Iris towers.”

Yet it is chiefly in the historical memories connected with Iris

Pseud-acorus that interest centres. The Fleur de Luce, Fleur de Lis, or Floure de Luce everyone has heard or read of as the blazon that was chosen by King Louis VII. of France when he commenced his crusading expedition, and from which circumstance it was designated Fleur de Louis, ultimately transformed into the unmeaning name it now bears. All, too, have heard how our English Edward III. adopted the Fleur de Lis after the battle of Cressy and incorporated it with the Royal arms. These are facts so well known as scarcely to bear repeating except in the way of incidental reference. But that is only the pleasant part of the history of the Fleur de Luce. It is to the French Revolution that we must look for the counterpart of that history, when the passions of an infuriate and ignorant mob were directed to the total destruction of every emblem of royalty. Then not only was the harmless insignia torn down and obliterated wherever it was present, but the crime of wearing or preserving any article marked with it was punished with death. Even in the present advanced times this spirit still seems to prevail, for not many months since it was announced that the Municipal Council of Paris proposed to erase the Fleur de Lis from all public buildings. So much for what may be termed the romance of this interesting species of Iris, which, though less gorgeous in the colouring of the flowers than some of its more favoured relatives, it yet surpasses all in its suggestiveness to a contemplative mind. As regards the properties of the plant little need be said. The leaves possess a peculiar odour as of rancid bacon, but less powerfully than *I. foetidissima*, while the juice of the root is very acrid and is said to be a strong aperient. A variety with finely variegated foliage is in cultivation. The leaves are broadly margined with yellow, the flowers being large and similar to the type in colour and form. Both of this and the species the colour of the flowers sometimes varies to nearly or quite white.

I. oehroleuca is a stately species, somewhat resembling *I. Pseud-acorus*, but rather more attractive. The stems rise to the height of 3 or 4 feet, and bear very large yellowish flowers marked with white. A still later variety is known by the appropriate name of *gigantea*, which reaches the height of 6 feet, the flowers being pure white. Both these produce their flowers comparatively late in the summer, and are worth growing, as they succeed in any moist position. The typical species is well figured in the first volume of the “Botanical Magazine.” *I. Monnieri* is a species from Crete, allied to the last two but with paler flowers; it is very rare, being found in few collections. Its chief recommendation is the lateness of the flowering, particularly in the neighbourhood of London. *I. versicolor*, a native of the United States, especially in Virginia, Maryland, and Pennsylvania, has been some time in this country, and is justly admired for its beauty. The stem has a peculiar crook or elbow, which is a distinctive mark of the species. The flowers are produced in June; they are of medium size, and have small pinkish or flesh-coloured standards, white stigmas, and rounded rich purple falls veined with a darker tint. It is extremely attractive, and like many others thrives freely in almost any soil and position except the driest. Several varieties are in cultivation, the best of which are *Violacea* with violet-coloured falls and standards, the former being of the deepest shade. *Purpurea* has rich purple falls and rosy white standards. *Atro-cerulea* has violet standards and fine blue falls; while *Pallida*, as its name implies, has light-coloured flowers, the predominating tint being lavender. *I. virginica* is said to have been cultivated in 1758 by Phillip Miller, and it therefore takes rank among the old inhabitants of our gardens. It is a pretty species and appears especially happy in a moist position, but it must not be a stagnant moisture, as that is destructive to this and all other similar forms in cultivation. Michaux found it abounding in the marshy districts of Virginia, which sufficiently indicates its requirements; it flowers in June, the falls being of a deep clear purple hue beautifully veined, and the standards bluish. The varieties *Columnæ*, *Hansoni*, and *pulebella* are deserving of a place in gardens; they chiefly differ from the type in their light or dark shades of purple, blue, and lavender. *I. spuria* is an old and well-known species with handsome flowers, the falls of which are rich purple, with blue upright standards. It was known to Parkinson, who describes it under the name of the “Greater blew Floure de Luce with narrow leaves.” The specific name was given by Linnæus from its not furnishing any decided characters to aid in its determination. About half a dozen varieties are grown, all very beautiful, the best being *cærulea*, *ilacina*, *halophylla*, *pallida*, and *desertorum*, which vary from purple to lavender, yellow, and white. It does not require any special treatment. In concluding this section *Iris foetidissima*, the Stinking Gladdon, may be noticed as the only other British species. It does not possess any particular attractions, but there is a form with finely variegated leaves which is useful as a decorative plant.

Both the popular and the botanical names of the species refer to the odour of the leaves, which has been compared, as in *I. Pseud-acorus*, to rancid bacon, or by some has been thought to

resemble roast beef and Garlic, and it has from that been occasionally termed the Roast Beef Plant.

In the same group as *I. Kämpferi* (referred to on page 215) are

Fig. 61.—IRIS LONGIPETALA.

two other species that deserve notice—namely, *I. longipetala* (represented in the annexed engraving), and *I. fulva*. *I. longi-*

petala is one of the two beautiful Irises found by Mr. Douglas during the Beechey expedition, and like *I. Douglasiana*, to which

I have previously referred, the flowers are of great size and substance. The falls, as the specific name implies, are very long, finely striped with lilac, the streaks radiating from the centre on a lighter ground; the standards and stigmas are of a purplish blue tint. It is one of the finest of the Irises, but is by no means well known in gardens at present, though it is included in the large collection of choice hardy plants grown by Mr. Ware at Tottenham. I have not had an opportunity of obtaining flowers for sketching, and the engraving has been prepared from an excellent coloured figure of the species in the "Botanical Magazine," plate 5298.

I. fulva is interesting from its resemblance to *Hemerocallis fulva* both in shape and colour, the falls and standards very nearly equal in size and spreading. It is very distinct in general appearance from all other Irises of the beardless section, and is the last in that division that calls for special notice.—L. CASTLE.

ROSA RUGOSA.

THIS is popularly called the Japanese Rose, and a charming shrub it makes. It should never be budded on standards, but upon dwarf Manetti stocks, so as to acquire a true globular bush form, which it soon does, and is then so ornamental that everybody admires it. Many times have I found visitors warmly discussing its charms this season. Each one appears to have discovered some especial merit. The dense spreading yet compact habit of growth; the handsome dark evergreen foliage, so stout in texture, and so especially ornamental in winter; the abundance of its flowers, and their delicious perfume; and above all just now the numerous clusters of bright red hips nestling among the foliage, the brightness of every one of them most charmingly refined by the exquisite bloom with which it is covered.—E. L. O.

CHAPTERS ON INSECTS FOR GARDENERS.—No. 12.

NEW SERIES.

PROCEEDING with our notice of the predaceous beetles in the family Adephaga, we should observe that some of these are unjustly suspected of doing mischief. During the past summer we received specimens of a small *Carabus*, or ground beetle, to which one gardener gives the name of "black jack," as others perhaps may also, and this was thought to have caused damage to a crop of Strawberries; but inquiry into the case rendered it evident that the offenders had been of another kind, probably a small species of mollusc, and upon these the beetles had been preying. Some colour to the mistake, in this and similar instances, is given by the fact that the actual depredators have often disappeared through the agency of some foe or parasite before the injury they have done is remarked by the gardener, and amongst parasite insects there are several that attack both our friends and our enemies; for the active flies of the genus *Tachina*, the larvæ of which help to diminish the number of caterpillars, especially that of the Gooseberry grub, and which sometimes attack the destructive weevils, are also found upon those useful beetles the *Carabi*.

These *Carabi*, however, occasionally hunt their near relatives. Thus *C. monilis* seeks out a smaller beetle, which is gifted with a defensive power, from which it has received the name of *Brachinus expulsores*, or the Bombardier. Their usual habitat is damp places, where the *Carabus* seeks for them, and should one of these discover a Bombardier forthwith a stern chase begins. The smaller beetle is less agile and would soon fall a prey to its assailant; but finding it is losing ground it pauses and fires off from its tail a mimic artillery—a few drops of fluid which volatilises in the air like a tiny puff of smoke. The hunting insect pauses, and frequently stops in its career; if, however, it should recommence the pursuit the *Brachinus* can fire again and yet again. But for all that it is possible that the *Carabi* do succeed in capturing and killing some of these beetles. Many of these ground beetles keep themselves concealed through the day, though some of them may be seen traversing the beds, or crossing the paths, intent upon their particular prey, such as the greenish-coppery *C. cancellatus*, or the larger violet-coloured *C. violaceus*. A very useful species is unfortunately scarce in Britain; this is *C. auratus*, which seeks out the female cockchafer when crouching on the ground with a view to deposit a batch of eggs. The active *Carabus* having laid hold of the slow-moving cockchafer kills it and tears it asunder, so that by this means a check is given to the increase of that species. The Rose beetle is also captured by this *Carabus*. In the larval condition the beetles of this family live under moss in trunks of trees or similar situations, feeding on other insects. The French have, for some time past, been awake to the advantage of encouraging such beetles in gardens,

and have even taken measures for introducing colonies of them where they are scarce.

The Sunshiners form another family amongst the Adephaga. Most of these beetles are green or greenish blue, rapid in their movements, and destroyers of smaller species. They belong to the genera *Amara* and *Pæcilus*. A curious superstition prevails in some counties that it is unlucky to kill a Sun Beetle; it is certainly undesirable to diminish the number of insects that are always harmless, and mostly helpful to the successful culture of gardens or fields. Some of them are especially partial to the margins of streams, marshes, and the seashore. Usually they are so constituted as to be able to master insects larger than themselves, though they frequently prefer small fry. These Sunshiners have sundry relatives of a sooty or pitchy hue, which are not uncommon about gardens or outhouses, and they are more inclined to deeds of darkness, seldom showing themselves by daylight. We may mention two of these in passing—*Pristonychus terriicola*, a beetle of elegant shape, with faint lines upon the bluish-black wing-cases, and which feeds upon various insects indoors or without; and *P. leucophthalmus*, of a deeper black, having long slender palpi, and wing-cases covered with tiny punctures. Both these are about three-quarters of an inch in length, and the latter is notable because it is reported to hunt and kill that objectionable insect the cockroach.

The second division of these predaceous beetles is suitably called Hydradephaga, containing a part of the water beetles, and at once distinguishable from their land brethren by the long flattened hind legs, fringed with hairs also, and which act famously as oars. In ravenous habits these surpass the Adephaga; perhaps their life under the water stimulates the digestive process! The Gyrini or whirligig beetles (a name that is oddly printed in some books "whirlwig") are to be found at one time beneath the water and at another running rapidly upon its surface, where they capture the little beetles and flies that may fall into the water. The great water beetle (*Dyticus marginalis*) is a powerful swimmer, and it does not limit itself to insects and molluscs, for it has been taken when attacking fish. Juvenile naturalists occasionally haul up these beetles with the intent of placing them in an aquarium, and while grasping one in such a way as to avoid the jaws, they are surprised to discover that the beetle, by backing when it is in the hand, can inflict a wound with a sharp process on the under side of the body. But, from their destructive habits, these and similar water beetles are unfit tenants of any aquarium intended to be a home for other living creatures. If it be wished to observe them, the only way is to give them a glass vessel to themselves, when they must be freely supplied with other insects or fragments of meat. In ponds and narrow streams the Dytici may be often seen coming to the surface, where from time to time they elevate the abdomen, expelling air in that way, or receiving a fresh supply, which is carried about in a hollow under the wing-cases. At night these beetles take excursions through the air, not unfrequently picking up insects on the road as they go from one pond or streamlet to another. The larvæ of *D. marginalis* has sometimes been called the water tiger. It is a slender but very ferocious creature, armed with a pair of hollow mandibles, which act in an almost similar manner to the fangs of a snake. Its growth is, however, gradual, and during most of its life it hides under the mud, though obliged to rise at certain periods to breathe.

The other important group in the Hydradephaga is represented by the Gyrini, to which allusion has been made. Quite a contrast in size are these when placed beside the huge Dytici, and their movements on the surface are so pleasing to look at, especially when the sun shines upon their polished bodies, that a colony of them is an agreeable addition to a pond in the parterre; only beware of handling one of them should the insect be the common whirligig (*G. natator*), for this species has the faculty of emitting a defensive liquid of an odour not by any means fragrant. *G. natator* is blue-black in colour with a reddish mouth, and about the size of a large ladybird; each it may be observed, as it glides to and fro, or suddenly dives beneath the water, to carry at its tail a small bubble of air. The Gyrini have much shorter antennæ than the rest of the water beetles, but the eyes in the genus are formed in a very unusual manner. Each eye is divided by the protruding portion of the head that bears the antennæ, and one part of the eye is directed upwards, the other sideways, having a comical appearance under a magnifier; this arrangement being suited to the usual habits of these insects.—J. R. S. C.

DIGESTION IN PLANTS.—Dr. Lawson Tait has recently investigated afresh the digestive principle of plants. While he has obtained complete proof of a digestive process in *Cephalotus*, *Nepenthes*, *Dionæa*, and the *Droseraceæ*, he entirely failed with *Sarracenia* and *Darlingtonia*. The fluid separated from *Drosera*

binata he found to contain two substances, to which he gives the names "droserin" and "azerin." Dr. Tait confirms Sir J. D. Hooker's statement that the fluid removed from the living pitcher of *Nepenthes* into a glass vessel does not digest. A series of experiments led him to the conclusion that the acid must resemble lactic acid, at least in some of its properties. The glands in the pitchers of *Nepenthes* he states to be quite analogous to the peptic follicles of the human stomach, and when the process of digestion is conducted with albumen the products are exactly the same as when pepsine is engaged. The results give the same reactions with reagents, especially the characteristic violet with oxide of copper and potash, and there can be no doubt that they are peptones.—(Nature.)

THE POTATO DISEASE.

IN a previous communication I stated that the disease was due to a rupture of some of the organs by a glut of rain during some period of the plant's growth, and that this was capable of proof. I now give some methods of proof convincing to my mind. 1, After heavy rains attended by a muggy densely saturated atmosphere, examine microscopically all the parts of the plant at any stage of its growth, and many of the cells will be found ruptured. 2, Gather from reliable sources the results of growing Potatoes under glass, and where they are free from excessive moisture, and the evidence will show the absence of disease. 3, Securely fix a large light over a portion of your patch of Potatoes, so that the surrounding conditions of growth shall be felt beneath, but that the rain shall be thrown on those growing near; and if the season be at all wet the sheltered Potatoes will be sound while those receiving the extra rain will be diseased.

The state of the Potato crops this season is another proof, at least to me. This year the heaviest rainfall has been somewhat limited to the western and midland counties, and, so far as I know, in these counties only have the Potato crops suffered severely, particularly so where the land is heavy and ill-drained. A friend in Fifeshire tells me his crops are very heavy and quite sound. The rainfall there in June, July, and August has been considerably less than in the Vale of Gloucester where the disease prevails largely. Similar experiences induce me to suggest that you invite qualified correspondents in selected localities to give you the rainfall from May to August inclusive, and the state of the Potato crops in their districts. The evidence of these facts will most certainly prove that where an excessive rainfall has occurred, there the disease has prevailed—modified of course by soil, drainage, varieties, and culture.

These facts have convinced me that wet seasons and not fungus cause the disease. It may well be that what is superabundant moisture to the Potato is a condition suitable to the growth of fungus; what is disease to the one is vigorous health to the other, but still excessive moisture is the cause of the disease, and fungus is a result.

It will be interesting to know if others have followed this line of thought and experiment, and with what results. The importance of the subject is worth the attention of the Meteorological Office and the authorities of Kew Gardens. I do not think we can conquer the disease, because we cannot order the seasons, but we can do much to limit its ravages by cultural directions. Those which I have successfully practised shall be sent to you for another issue.—AN INTERLOPER.

I DO NOT know whether your readers are tired of this subject, but I am like the "Song of the Brook," I could go on for ever. It is a subject which interests me and to which I have devoted considerable time. I see "LINCOLNSHIRE POTATO GROWER" says that I have not contradicted his statement that nine-tenths of my book is composed of the experience of others. With regard to this, some years ago I wrote a series of articles in this Journal, in which I treated of the disease from a purely theoretical point of view without referring to the writings of others at all. Now those articles were criticised, and were found fault with because I had not referred to the writings of others. So much for critics. At the same time I admit that my former critic would have been right if it had been a general treatise on the disease, which the book is; and for anyone to write a treatise of that nature entirely from his own experience, and without referring to the writings of others, in my opinion would be a great mistake, and the book would not be worth reading. It would be like the play of Hamlet with Hamlet left out.

Then, again, he says it is not a practical book at all. With regard to this I entirely differ from him. It is full of practical information from beginning to end. Again he says, "Pulling the tops off has been of great benefit, and this is not mentioned," but

on referring to page 57 and reading it over carefully anyone may see that it is.

Then again he says, "Neither is the theoretical plan for the extinction of the disease of any practical value, at least according to the authority of Mr. Worthington Smith." Oh yes! we are to sit back in our chairs, fold our arms, and look complacently on as we have been doing for the last thirty-five years! When railways were first invented, letters used to be written by scientific men to various journals saying that it was impossible for any railway train to travel at the rate of sixty miles an hour in consequence of the resistance offered by the pressure of the atmosphere; but that we all know was found to be erroneous. Now let us examine some of the statements quoted from Mr. Smith:—"If Potatoes were taken into an island in the middle of the South Pacific, or transported for miles upwards into the air, or submerged for years in a river, they would yet be liable to contamination from the *Peronospora*, for the spores of the fungus are everywhere. Spores are present everywhere, and can no doubt be carried through the air across a sea or ocean as readily as over a hedge. Spores everywhere sail with the wind and at the same speed. Nothing is better known than the descent of spores, pollen, and other minute organisms on to ships in mid ocean." The spores of the fungus do spread about there is no doubt, but the remarks of Mr. Smith are much too sweeping. Instead of an island in the South Pacific let us fix on one in the South Atlantic—viz., Tristan d'Acunha. This island, as some of your readers know, is about half way between the Cape of Good Hope and the Argentine Republic in South America. Now Potatoes have been grown on this island for more than twenty years without any sign of disease whatever, so that it is very evident they are safe from the spores notwithstanding what Mr. Smith says; and with regard to the Isle of Man, in my opinion the result would be the same if the island were once cleared of the disease. Other people may differ from me in opinion, but the question can only be satisfactorily decided by putting it to the test of practical experience, which I am glad to say is being done in Argyleshire.—THE WRITER OF THE BOOK.

TREES AND SHRUBS FOR PLANTING NEAR THE SEA.

IN response to Mr. B. Cowan's query, I have noticed the greater portion of the undermentioned flourishing near the sea and not far from both tin-smelting works and a tanyard. Plants and trees that will thrive in such places will probably succeed with Mr. Cowan. *Trees*.—*Cedrus Deodara*, *Acer pseudo-platanus*, *Ailanthus glandulosa*, *Cratægus oxyacantha*, *Hippophaë rhamnoides*, *H. conferta*, *Ilex aquifolium*, *Pinus Cembra*, *P. insignis*, *P. Pinæa*, *P. Pinaster*, *P. Strobilus*, *Pyrus Aria*, *Quercus coccinea*, *Q. Cerris*, *Q. Ilex*, *Q. robur*, *Tamarix gallica*, *T. germanica*, *Tilia europæa*, *Ulmus nigra*, *U. rubra*, *U. stricta*. *Shrubs*.—*Aucuba japonica*, *Berberis aquifolia*, *B. Darwinii*, *B. fascicularis*, *B. vulgaris*, *Arbutus procera*, *Escallonia macrantha*, *E. Ingrami*; *Euonymus*, silver, golden, and the common green-leaved varieties, the latter is the best; *Syringa persica*, *Ligustrum japonicum*, *Sambucus nigra*, *S. racemosus*, *Garrya elliptica*, and the fine ornamental Grass *Glycerium argenteum*. Should I notice any others I will not fail to communicate their names. I confess I am unable to answer Mr. Cowan when he asks, "Can it be explained why Elders withstand the effect of chemicals?"—W. ROBERTS, *Penzance*.

THE MOULD OR FUNGI ON THE HOP PLANT, PEACH TREES, POTATOES, AND GRAPES.

I HAVE this year had an opportunity of seeing and carefully examining the disease called the Mould in the Hops, having visited several of the Hop gardens in Kent; and from inquiries made both of the masters and men employed in the cultivation of Hops, I have come to the conclusion that the mould is caused by the sun. When the Hop is in full bloom, if a shower of rain is followed by scorching heat, the very abundant pollen, which has already been rendered wet, becomes baked on the plant, and the fungus is then produced. Many facts bear this out. First, the Hops, I am told, looked well and gave the farmers hopes of a good crop up to the time of their coming into bloom, and the mischief was not perceived till a week or two afterwards, when the fungus had begun its destroying work. Being caused by the elimate, I am afraid the fungus cannot be prevented. By planting different varieties of Hops so as not to have them all in bloom, the risk of loss would, I think, be less than it is now.

The blister on the Peach trees I think might be traced to the same cause. I have found trees that have been lifted and replanted have been the worst affected. The trees were on a south wall

with an abutment or pillars projecting 10 inches every 12 feet. The blister could not therefore be caused by the cold east winds, as the pillars would prevent that. I have also seen the double-blossomed Peach and Almond trees as badly affected in the plantation as these were against the wall, and trees on a wall facing the west have been similar.

It is quite possible the Potato disease might be induced by a scald from the sun in the same way as it always commences after heat and showery weather just at the time the skin is setting, the fungus being the result; as heat and moisture always favour the growth of fungi, and hot dry weather always has the opposite tendency and seems to arrest it. This will account for the fact that if Potatoes which have been affected are taken up and allowed to remain in a large heap most of them will rot, while laying them thinly in a cool place will save many of them.

The rust in the Grapes I have no doubt might be traced to the same cause, produced by the steam from the hot-water pipes and the action from the sun; but the shanking I cannot believe to be so caused, as it is always clearly due to exhaustion. Lifting and replanting the Vines in a fresh border will entirely remove all shanking till the Vines again become exhausted.—GEORGE CLEMENTS, *Hazeley Manor, near Warwick.*

KITCHEN GARDEN.

THE weather during the present autumn has been favourable for the eradication of weeds, and those who took advantage of it by hoeing frequently amongst the young autumn-sown crops will have benefited those crops considerably, and at the same time have imparted a neat appearance to the garden. The hoe is not only of great service in extirpating weeds, but the oftener it is used amongst such crops as Lettuce, Spinach, Cauliflower, and Cabbage, the less destructive will slugs be to the young plants. It is for this reason that sowing the seed in drills is preferable to sowing broadcast, when the soil amongst the young plants can only be stirred by a slow and tedious process. Weeds that are permitted to grow in the drills and seed beds of the crops named at this period of the year, render the young plants tender by excluding the air from them when every effort should be made to render them hardy. With this object in view—and it is of great importance—the plants should be thinned out sufficiently and in good time to provide for each sufficient space to ensure its becoming sturdy and to the greatest extent hardy. This remark applies to all crops that are sown in the autumn, for overcrowded growth now is an almost certain precursor of failure in a few weeks or months hence. Thousands of plants are sacrificed annually through the neglect of timely thinning, and the matter demands special attention at the present time. Plants for the earliest crops have been already transplanted, and as those from successful sowings become large enough they must be transferred to the positions prepared for them, and the sooner such work is completed the better. Celery should be earthed before the occurrence of severe frosts, as if the plants are in the slightest degree injured before the earth is applied decay will ensue, and the value of an important crop will be seriously impaired.

FRUIT HOUSES.

Vines.—Late Vines judiciously aided with fire heat in the spring will have finished off crops of ripe well-coloured fruit, which will winter much better than Grapes that still require artificial heat to ripen them. With the Grapes thoroughly ripe the wood and foliage will be well matured, so that all spray and laterals may be removed down to the chief buds. Liberal ventilation will be required upon all favourable occasions, and as the foliage ripens the temperature may be allowed to fall to a minimum of 50°. Late Grapes require to hang some time before being in suitable condition for table. These and other ripe Grapes will require examining twice a week, and to prevent dust settling on the berries sweeping and raking must be avoided as much as possible. There must not be any further delay in pruning Vines that are intended for supplying Grapes early in May. Dress the Vines with an insecticide, and clean the house

thoroughly, keeping it cool to ensure complete rest until about the second week in November. Vines that were pruned last September, and intended to afford ripe fruit in March or early April, should now have the house closed, but do not allow the day temperature to exceed 65° without free ventilation. Fermenting material inside will assist the Vines in starting, but it is necessary that it be prepared by damping and turning it over a few times in a heap. If the roots of the Vines have access to outside borders, some fermenting material should be placed on them at least a fortnight before closing the houses, or at least the application of fire heat. The earliest Vines in pots may now be started, and if a little bottom heat can be afforded them they will start better; the temperature at the base of the pots not exceeding 70° until the Vines are growing. The temperature at starting should not exceed 55° artificially, and 65° by day without free ventilation, but it may gradually be increased to 65° by day artificially, and 70° to 75° with sun heat, and 60° at night, falling to 55° in the morning. The canes should be slung in a horizontal position to induce them to push their buds evenly throughout the length of the rods. The house and Vines should be damped two or three times a day. Young Vines will show a disposition to continue growing, but this must be checked by moderate stopping, and the ripening of the wood facilitated by keeping a high and dry temperature through the day and by shutting off the heat and opening the ventilators by night. Where bracken is plentiful a good supply should be prepared for covering up late borders before the shutters are placed on for the winter.

Pines.—Young growing plants should now be arranged so as to obtain the fullest benefit of sun heat. With the diminution of this a corresponding reduction of temperature should take place until it reaches the artificial winter standard—viz., 55° to 60° at night and 65° in the daytime. Whenever circumstances are favourable ventilate freely. Pay great attention to watering at the roots, making a weekly inspection, and whenever a plant needs water supply it copiously at the same temperature as that of the house. Continue 70° as the minimum for fruiting plants, 75° artificially in the daytime, and 80° to 90° with sun heat, closing at 85°, sprinkling the surfaces of the pathways as they become dry, and occasionally syringe the plants on fine sunny afternoons. Keep the bottom heat steady at 85° to 90°. Avoid too much water at the roots, as this is apt to cause the fruit when ripe to cut black at the centre, especially during the winter and spring months.

Peaches and Nectarines.—The trees in the earliest forced house have now lost their foliage, and if any pruning or dressing be needed the trees should be attended to before tying them to the trellises. The borders may be pointed over, the loose surface soil removed, fresh loam and decayed manure supplied, adding about 12 per cent of half-inch bones or bone meal, and a similar per-centage of wood ashes, following with a good watering. The roof lights may remain off until November, when it will be necessary to replace them to ward off heavy rains and probably snow, air being freely admitted, except during frost. Allow the outside borders of early houses to have the benefit of whatever rains may fall in October, afterwards protect them with litter, shutters, or tarpaulin. The foliage of trees started early in the year will be falling, and should be cleared away as they fall. When they are all down lose no time in having the house thoroughly cleaned and the trees pruned, dressed, and tied to the trellises, top-dressing the border as before advised unless the trees have been lifted or root-pruned this season, when it will not, of course, be necessary. Late houses should be proceeded with as the trees are cleared of their crops in lifting wholly or partially as may be necessary, any operation necessitating interference with the roots being best performed whilst the trees are in leaf. Where there is any shifting of trees or transplanting from walls needed it should be done whilst the trees are in leaf, the wood and foliage being mature before doing so, as immature growths are liable to shrivel if the trees are disturbed at the roots too early.

PLANT HOUSES.

Stove.—Where climbing plants are trained up the rafters and flower in the summer, such as Aristolochias, Passifloras, &c., they should be cut freely back now to allow plenty of light to reach the plants that

stand under them; but *Ipomæa Horsfalliæ* and plants of a similar habit that flower through the winter must not be pruned now, as what is cut away will necessarily reduce the number of flowers. The following climbers are in flower now:—*Bougainvillea glabra*, *Stephanotis floribunda*, *Passiflora Madonna*, *P. kermesina*, *P. princeps*, *P. calycina*, and *P. Countess Guiglini*; *Allamandas* and *Dipladenias*. *Stephanotis floribunda* must not be cut-in at this season. The best plan to insure bloom with this plant is to grow it in a light position, and not too moist, allowing it to remain on the roof through the winter and for flowering, after which thin-out or cut well-in, and encourage fresh growth for the ensuing season.

Allamandas intended for early flowering that will need to be cut back at the commencement of the coming year should now receive no more water than will keep them from flagging severely. Keep the plants near to the glass in a warm dry atmosphere, and a free circulation of air where it will not affect other plants injuriously. Ripening stove plants by plenty of light and a moderate dry atmosphere is every way more satisfactory than the low temperature sometimes resorted to to induce rest. *Ixoras* that have become too large should now be cut well back; and if there is any mealy bug wash the plants thoroughly with an insecticide, repeating the operation two or three times in the course of ten days. Where stove plants are grown in large numbers and sufficient heat is employed to have them in good condition mealy bug increases rapidly. This is the best time in the year to endeavour to destroy it, as an onslaught now made and persisted in for this and next month, when the insects increase very slowly and the plant is at rest and better able to bear an application of the mixture, will prove most effectual. Every part of the plants from the soil to the point of the shoots, every crack and inequality, must be thoroughly washed, and this should not be done once but half a dozen times, so that no insects escape. Old tan or similar material must be cleared away, every hole or crevice in the brickwork stopped up, and thoroughly wash the walls with lime, the woodwork where necessary being painted thoroughly.

Begonias of the winter-flowering section should receive every encouragement, supplying liquid manure, giving all the light possible, and sufficient heat, but no more than is requisite to induce their flowers to open freely. So treated the flowers in a cut state will last much longer than those from plants grown in a hot, moist, and dark house.

Richardias.—A few plants should now be placed in heat for early flowering; a temperature of 55° at night is ample, and 65° by day, as when kept warmer they become weak in leaf and flower, not bearing moving to a conservatory where the temperature is lower; therefore to ensure dwarf sturdy plants keep them near the glass, keep them well supplied with liquid manure, and ventilate the house moderately.

Lily of the Valley.—A few pots or pans of these should now be placed in heat, the flowers being at no time more acceptable than at the close of the year. Roots that have been forced in spring and continued under glass until the growth was completed, and then placed outdoors to rest, will have well-developed crowns, and can readily be forced. At this season a bottom heat of 85° to 90° for single crowns is absolutely essential, so as to give the roots a start in advance of the tops, otherwise they are apt to go blind. Covering them with pots is often attended by the flowers going blind when the cover is removed, and if pots are employed at all they should be removed gradually so as to inure them by degrees to full light. Place a few more Roman Hyacinths, Paper White and Double Roman Narcissus, in moderate heat to insure a succession of flowers; keep them near to the glass, and in a temperature of about 55° artificially.

NOTES ON VILLA AND SUBURBAN GARDENING.

FLOWER GARDEN.

Pelargoniums.—Frost has already been experienced in some districts, and may shortly be anticipated in most parts, however favourably situated they may be; therefore the lifting and potting of choice *Pelargoniums*, or of any of which there are insufficiency of cuttings struck, should no longer be delayed. The common varieties may be

packed thickly in boxes, but those of the bronze, zonal, or tricolor types should either be potted off rather thickly in 5-inch or 6-inch pots, or singly in 3-inch pots. Lift the plants with a fork, pick off the oldest leaves, trim-in the roots with a knife, and place the plants in pots or boxes firmly. Employ shallow well-drained boxes; the pots to be also well drained. Any common light sandy soil will do, provided it is not dust dry. With regard to watering, much depends upon where the plants are to be wintered. In any case no water should be given till the roots are healed, or damping off will probably be the result. Those that are to be kept in frames should have a dry well-drained bottom, receive abundance of air, and have the decaying leaves frequently picked off. The best places for them are on the back shelves, the swinging shelves of vineries, or the back shelves of the greenhouse; but the autumn-struck cuttings should receive the preference for these positions, the older plants, especially the common varieties, being most hardy. Old plants are sometimes cut back when lifted, but the above plan is best, and besides it gives an opportunity of striking more cuttings in the spring. Autumn-struck plants may be placed in their winter quarters, but should receive as much light and air as possible, and be kept almost dust-dry at the roots to prevent them making strong growth, the result of which is to make them much more susceptible of injury from frost and damp.

Ageratums and Lobelias.—Although these come remarkably true in some instances from seed they are best propagated by cuttings, as they then make a much more even and more floriferous growth. Select any that are of marked superiority, and lift with a small ball. Place the *Ageratums* in 6-inch pots, and the *Lobelias* in 4-inch pots. Drain well, employ moderately rich soil, and pot firmly. Water them, and place in a somewhat shady position in a house, or keep them rather close in a frame till established. Both may be trimmed-in, but not very closely. *Verbenas*, with the exception of *V. venosa*, do not lift well, neither do *Heliotropes* and *Petunias*; but where cuttings were not struck during August the attempt should be made both to strike cuttings if a little bottom heat is available, and also to lift a few old plants, the latter to be treated as advised for the *Ageratums*, using, however, 5-inch pots for them. *Verbena venosa* strikes most readily from the roots in the spring, and as they are not quite hardy a good quantity should be lifted with the roots entire if possible, have their top trimmed-in, and be packed thickly and flatly in shallow boxes. If rather moist soil be used no water will be required, especially if they be wintered in cold frames.

Abutilon Thompsoni and *Veronica Andersoni variegata*.—These after doing good service in the flower garden can be readily lifted and prove equally as effective in the greenhouse during the dull winter months, and be much superior to any that may have been kept in pots. Lift with a good ball which may be reduced so as to go into 8-inch pots, and still smaller in the case of the *Veronica*. Employ good soil, water after potting, and keep them somewhat close and shaded for a time.

Dahlias.—Those that are unnamed should each have a label bearing a description of the variety for future guidance fastened to the bottom of their stems, and old labels renewed where required as soon as they are damaged by a slight frost, or if a very severe frost be imminent cut down the plants to within 9 inches of their base; lift carefully, clear the tubers from soil, and when these are thoroughly dry pack them away in a dry shed. A little dry soil may be worked in among the tubers, and they should be protected from severe frosts. They will keep plump in a cool dry cellar if placed in a single layer without any soil about them.

Cannas if in a well-drained position may be wintered in the open ground, provided they are well protected with leaf soil, coconut fibre, or other material; but the simplest plan is to lift the clumps with a little earth attached and store away with the *Dahlias*. Clumps wintered in a cool dry cellar started readily last spring, whereas many in pots wintered in a cool house failed to start afresh. The Golden and White Marguerites (*Chrysanthemum frutescens*) may be readily lifted, and can be wintered in a cold frame or greenhouse. A strong plant will give a number of cuttings in the spring, which will strike readily in heat.

Violas and Shrubby Calceolarias.—These require similar treatment,

being propagated by cuttings at this time of the year. Shallow cold frames are suitable both for striking and wintering them, fire heat being injurious to both. Place a layer of rough material in the bottom of the beds for the frames, over this place a layer of light sandy soil, about 6 inches in depth, and on this place a layer of sifted soil, which may consist of equal parts leaf soil and loam, with a liberal quantity of either road grit or sand. Make this level and firm, sprinkle over a little more sand and dibble in the cuttings, in the case of the *Calceolarias* 2 or 3 inches apart each way, and the *Violas* a trifle thicker. The *Calceolaria* cuttings may be about 4 inches in length, trimming off the lower leaves and cutting to a joint, and the *Violas* made in the same way may be about 3 inches in length. Water them in through a fine rose pot, keep close and shaded from bright sunshine during the day, and protect with mats during frosty weather.

Miscellaneous Bedding Plants.—*Echeveria metallica*, *Pachyphytum braetiosum*, and *Kleinia repens* should be lifted and either potted off singly into small pots or they may be packed closely in boxes. Any light soil will suit them, and they may be wintered in a cool greenhouse, providing they receive but little moisture at the roots. If plants of *Mesembryanthemum cordifolium variegatum* are lifted they should be potted firmly in 3-inch pots, employing sandy soil. Place them on a shelf in a rather warm greenhouse, and water sparingly. *Alternantheras*, *Coleus Verschaffeltii*, and *Iresines* when lifted should be placed in small pots, and require the temperature of a plant stove to establish and also to winter them. *Sedum glaucum* is quite hardy, but a few roots of *Mentha Pulegium gibraltaria* should be lifted and wintered in boxes, or planted out rather thinly in cold frames, as it succumbs during a severe winter. *Echeveria secunda glauca* is not quite hardy, and should be packed away closely in a somewhat dry position where they can be protected during severe weather. They may be packed on their sides in banks made against a warm wall, or in cone-shaped heaps, and be covered with mats during severe weather. They may also be tied-up in bunches and suspended in vineries on the back walls of greenhouses. Cuttings of the useful and hardy *Euonymus radicans variegata* may yet be inserted in sandy soil under handlights or in the open, and a handlight is also suitable for the present propagation of *Veronica incana*, *Leucophyton Brownii*, and the Golden Thyme.

TRADE CATALOGUES RECEIVED.

Wm. Rumsey, Waltham Cross.—*Catalogue of Roses.*

L. Spath, Köpniekerstrasse, Berlin.—*Catalogue of Plants, Shrubs, and Trees.*

André Leroy, Angers (Maine-et-Loire), France.—*List of Trees and Shrubs.*

Hogg & Robertson, 22, Mary Street, Dublin.—*Catalogue of Bulbs.*

Osborn & Sons, Fulham, London.—*Catalogues of Fruit Trees, Hardy Trees, and Shrubs.*

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (W. C. B.).—The "Garden Manual" contains much more practical information on the subjects to which you allude than does the other book which you mention; but only large and expensive volumes contain "full details of the culture and forcing of all kinds of plants, vegetables, and fruits during winter." You will find the "Garden Manual" very useful, and further information can be had through the columns of the Journal.

Old Hotbeds (Idem).—If the manure, as it usually is after fermenting in heaps for some months, is in a moist and decayed state, it is of no further use for heating purposes, and is only of value, and this value is great, for enriching the soil. Any dry portions may be shaken out and mixed with fresh stable manure and leaves for future beds.

Journalism (O'S., Dublin, and Others).—We are obliged by your letters, but it is not necessary to publish them. The circumstance is amusing, and the article to which you allude is certainly original this time, and not purloined. We have not the slightest objection to its publication, as it is a confession of a disreputable practice.

Pruning Fruit Trees (F. J.).—As you say your trees have been well attended to during the summer and need little winter pruning, we presume that all the sun and air possible have been admitted to the wood and foliage. Still you ask if the side shoots should be shortened to three or four leaves now. If the trees are in a healthy free-growing state the shoots may be so shortened at once, but if the growth is at all weak a few more leaves would be advantageous rather than otherwise. Winter pruning should be done as soon as the leaves have fallen from the trees. In removing trees it is desirable to take out all the roots possible, but we do not think the few of which you speak will be injurious to the other trees. If the timber intended for garden frames is creosoted a few months before the frames are used they will not be injurious to the plants that are placed in them.

Sam Young Apple (J. J., Cork).—You have been rightly informed that this Apple is of Irish origin. It is a small dessert Apple of excellent quality, and was introduced to public notice by Mr. Robertson, nurseryman of Kilkenny. You may safely add it to your collection.

Covering Latticework (Block).—As you require a screen we presume your latticework must be covered with an evergreen plant; if this is so there is none equal to Ivy. *Hedera Ragneriana* is a free grower and has handsome foliage. If an evergreen plant is not essential *Ampelopsis Veitchii* would be suitable. There are also evergreen Roses if you prefer plants of this nature. The Ivy if employed would need to be secured to the trellis for a time at least, but the *Ampelopsis* will cling to anything.

Wild Flowers of Great Britain (Rosa).—There is no Linnæan index to this work, but there is a systematic index according to the natural arrangement to each volume. No 231 is the last number.

Grapes Mouldy (B. D.).—Look over the bunches carefully every morning and remove every berry that has the slightest appearance of mould upon it, as one berry will speedily affect the rest, and the bunches if not attended to will soon be spoiled. Employ a little fire heat, and admit air freely by both front and top ventilators on all fine days. If you have plants in the house, water them with the greatest care, only pouring as much water in each pot as the soil will absorb, and not spilling a drop on the floor. The temperature of the house should not be much below 45° at night; this with a dry atmosphere will arrest the spread of the mould. Possibly the bunches have not been thinned sufficiently—the closer the berries are packed together the more liable are they to decay.

Roses in Ireland (Sligo).—We are glad to hear of your success. Roses are excellently grown in many Irish gardens, and there is no reason that they should not be grown there quite as well as in any part of the Queen's dominions. As a Rose for your porch you cannot do better than plant *Gloire de Dijon*. We do not know any other variety that so well combines all the properties you enumerate of being "hardy, a free grower, and producing fine and sweet blooms early and late in the season."

Propagating Ageratums (D. Webb).—We know of no more simple and certain mode than potting a few old plants from the beds, choosing the most sturdy. They may be partially cut down, and if well watered will soon be established. One good plant will afford cuttings in the spring from which a hundred plants may be raised by the 1st of May. It is rather late now for inserting cuttings, and taking up a few old plants will be the best mode of insuring a stock. They may be safely wintered in a greenhouse or viinery from which frost is excluded.

Wormleighton's Seedling Potato (Old Subscriber).—If this variety was raised, as we are informed it was, by Mr. Wormleighton, the above is its correct name. The name is spelled in three different ways by three gardening journals. We readily, as you know, answer all the questions we can that are submitted to us, and we are not accustomed to receive complaints from contributors whom we have endeavoured to supply with the most accurate information we could obtain. Your letter of last week contained a complaint not couched in the most pleasant terms. Our courtesy is at least equal to your own. You have asked us many questions, which we have answered; we have only asked you one, which you have not answered. We ask it again, Why do you not send your name and address?

Brussels Sprouts (A Reader).—Removing the heads from the plants may slightly accelerate the production of sprouts; but there is little gained by the operation, as if wet weather follows alternating with frost the centres of the plants may decay. You ought to have sown the seed earlier and grown the plants more generously had you required side sprouts at the present time. Some gardeners cut off a portion of the leaves from the stem for inducing an earlier growth of sprouts, but we have not tried the practice.

Wormcasts on Lawns (W. M. Grose).—Place a peck of quicklime in thirty gallons of water, stir well up, and allow it to stand for a few days until it is quite clear; then water the lawn thoroughly with the clear lime water. The worms will come to the surface, when they may be swept up and cleared away. This is an old and useful mode of eradication, but last year Messrs. Dick Radcliffe & Co. stated in our columns that if 1 oz. of corrosive sublimate is dissolved in a little hot water and then mixed well in forty gallons of pump water, and applied to the lawn with an ordinary watering can in the evening after a shower, the worms will disappear, and the grass will not suffer any injury.

Rhododendrons for Beds (C. D., North Wales).—If you order your nurseryman to send you dwarf and close-growing varieties they will, if transplanted occasionally, be some time before they "outgrow their quarters;" when they do so you must thin them, removing some of the shrubs to other positions. Severe pruning will not answer your purpose. October or early November is a good time for transplanting these shrubs and *Kalmias*.

Dianthus and Aquilegias (Idem).—In some soils and districts *Dianthus Heddewigii* passes the winter quite safely in the open ground, especially when the plants have been raised in the open and grown thinly, not thickly crowded in pots, pans, or boxes. Not knowing the condition of your plants we are quite unable to say if they will withstand the inclemencies of the winter; if they will not, the protection of a frame would be better than placing them in a greenhouse where they would inevitably become drawn and rendered too weakly for flowering well. Only a small per-centage of the seedlings of *Aquilegia cærulea hybrida* are identical with the original form, but a number of pretty varieties usually result from a packet of seed.

Wintering Fuchsias (D. A., Oron).—Your old plants that have ceased flowering and now losing their leaves may be safely wintered in any cool dark or

light place from which frost is excluded. Water should be gradually withheld from the plants, and in a short time all the leaves may be shaken off. Only sufficient water will then be needed to keep the wood fresh and the principal roots from shrivelling, and the plants will be as well under the stage of a greenhouse or in a cellar as in a light place until signs of fresh growth are apparent in the spring, when light is essential.

The Hesse Pear (*S. N., Leicester*).—You have been rightly informed that this old variety is one of the most certain, serviceable, and useful of orchard Pears. The tree is hardy and a great bearer, and the fruit is well known and esteemed in the markets of the midland and northern counties. It is not unusual for trees to bear 40 stones of 14 lbs. of fruit, and this sometimes when trees of other varieties are comparatively barren. You may safely plant a "tree or two" of this Pear in your orchard, and in due time they will give a good return for the space they occupy.

Physalis Alkekengi (*N. S.*).—The specimens you sent are the fruits of the Winter Cherry (*Physalis Alkekengi*) is a perennial herbaceous plant, often found in gardens, producing round red berries like Cherries, having an acidulous, slightly bitter, and not unpleasant flavour. They are chiefly recommended as a diuretic, but in America they are commonly eaten to quench thirst, and in Germany, Switzerland, and Spain they are served at the table as dessert along with other fruits. The fruit of *P. pubescens*, a native of North America, is eatable, and made into confections. It is now naturalised in Italy, where it is cultivated in gardens, and highly esteemed for its sweet acidulous berries.

The Peachblow Potato (*S. Gibson*).—On some soils and during favourable seasons the tubers of this Potato are of excellent quality. Some cultivators esteem it the best of the American round varieties. We have known it almost or quite equal when cooked to York Regents, and we have also seen the tubers close and watery. In this respect it varies almost as much as the Early Rose does, and this variety we have seen take the first prize in a competition of cooked dishes of all the most esteemed English varieties, while from other soils it was not fit to be eaten. As your soil is light, thin, and dry, you may safely try the Peachblow.

Storing Cannas (*Suburban*).—Some of the strong-growing varieties will keep safely in the ground if the surface is covered a foot thick with leaves or manure. It is found, however, the safest plan to take up the choice varieties and place them under the stages of cool plant houses, sprinkling a little soil amongst the roots to prevent them shrivelling. As the plants grow in spring they are divided and potted, and are not only in good condition for planting in May, but they can be arranged according to their heights in a bed or border. When wintered in the ground they often come up in an irregular manner, some of the plants being a foot or more high when others are only a few inches, and the effect is then not at all agreeable.

Measuring Flower Pots (*A. Boyle*).—When the diameter of a pot is stated by a writer it alludes to the width of the pot measured from the inside and just below the rim, as indicated by the letters A A in your diagram.

Names of Fruit (*Peter Marks*).—The Plum is Pond's Seedling. No. 1 Beurré d'Amanlis; 2, Beurré Diel. (*George Swales*).—There must have been some mistake in packing the fruit in the first instance, which was undoubtedly Alfriston, the same as the single fruit now before us. The three fruits sent to us this week are Reinette de Canada. (*J. Prothero*).—1, Gloria Mundi; 2, Hollandbury; 3, Federal Pearmain; 4, Alfriston; 5, Dumelow's Seedling; 6, Autumn Pearmain; 7, London Pippin. (*J. J. & S.*).—1, Mère de Ménage; 2, Gloria Mundi.

Names of Plants (*Aldermaston*).—*Lycopodium formosa*. (*Flora*).—*Pnlicaria dysenterica*. (*Nil Desperandum*).—1, *Doodia aspera*; 2, *Asplenium fontanum*. (*Junco*).—*Eupatorium purpureum*. (*J. B.*).—The specimen was very much crushed, but it resembles *Chrys aurea*. (*Mrs. B.*).—*Passiflora kermesina*. (*B. D.*).—The succulent plant is *Sedum earneum variegatum*. The tree is *Pyrus pinnatifida*. (*A. F. G.*).—Probably a form of *Verbascum virgatum*. (*A. Milne*).—1, *Gasteria verrucosa*; 2, *Sansevieria zeylanica*; 3, *Speechnen* very small, but it resembles *Gasteria latipunctata*. (*Rosa*).—The flowers sent are those of *Angræum bilobum*, and are very much smaller than *A. sesquipedale* which bears flowers with spurs exceeding a foot in length. (*Constant Reader*).—1, *Aristolochia Sipho*; 2, *Cedrus atlantica*; 3, *Ailanthus glandulosa*; 4, *Andromeda floribunda*.

POULTRY, PIGEON, AND BEE CHRONICLE.

ROTATIONS FOR CROPPING LIGHT SOILS.

THIS is a subject affecting a very extensive portion of the kingdom, for light soils are not confined to any particular county or district either in England, Scotland, or Ireland; and when we consider the variations of soil which come under the name of light land, and take into account the effect of the climate upon cropping, the importance of the task we have undertaken is at once indicated. At the same time it must be understood that systems of cropping go a long way towards influencing the mode of stocking the land, especially as regards sheep. It is said by some farmers that sheep do not pay—that is to say, they do not yield a direct profit; but there are two ways to view this matter, for in case we charge the animals with the cost of their food in crops they consume—that is, rent, tithes, rates, labour, tillage, manure, &c.—it will not always show a direct profit; but it must be borne in mind that this is the only way of selling our green

crops, &c., by the amount realised from meat made through their consumption, or by animals reared and sold as lean stock. The important point, however, next to be considered is the treading and manuring the land obtains by sheep, for under the heading of "Light Soils" we meet with land which would be absolutely sterile if it were not for the firmness contributed by the tread of the sheep during their consumption of roots and green crops upon the land. Again, it must be further considered that the manure left by sheep is almost the only way in which outlying land can be advantageously dressed and rendered productive of cereal and other crops for sale. We have thought it necessary to make these remarks, because in setting out various rotations of cropping the advantages of stock may not be directly referred to, but must be understood as part of almost any system of cropping connected with light land. Artificial manures often fail in their effect upon certain soils; and in the absence of sheep the labour of rendering the land firm, although aided by the use of the best implements, would be very costly, and even then never equal to the tread of the sheep.

Previous to any remarks upon actual cropping we must allude to certain applications upon light land, with the object of consolidating it and rendering it more capable of resisting the action of heat and drought; at the same time there is every reason why we should avail ourselves of an addition to the land of substances which will have a double action—that is to say, both mechanical and chemical. It is a common practice to apply to light and blowing sands, as well as thin gravels, a large and liberal dressing of clay of the most tenacious kind within reach, so as to diminish the cost of cartage; but the quantity to be used is a matter of great consequence, for if we give too heavy a dressing it makes the land work unkindly. We cannot therefore recommend more than 12 or 14 yards, or one-horse cartloads per acre, for one dressing, preferring to give another dressing at a future time rather than a heavy quantity at once. We also recommend a liberal dressing of manure salt, fishery salt, or kainit at the same time as the clay is applied. There is, however, a better dressing than the ordinary yellow, red, or blue clay, which usually contains but little chemical qualities besides potash, and this varying greatly in degree; we mean the calcareous clay, usually compounded of carbonate of lime and clay, and commonly called marl. The best marl is generally found in those districts where the chalk soils meet the clay. This is the best of all soils for the improvement of any light land, but especially where sharp white sand or fine gravel prevails. This marl not only acts its part in consolidating the land, but improves its chemical composition, the latter being as essential as the former. We often find these sands and gravels particularly subject to weeds, and also unfavourable to healthy vegetation, especially in the cultivation of Swedes and Turnips, which are, in the absence of chalk or lime in some compound or other, subject to club roots and rotteness, and otherwise possessing but little feeding value. We have been induced to enlarge upon this part of the subject because it is desirable to vary the crops as much as will tend to profit, for in those cases where the land will not bear pulse or cereal crops it is wise to turn them to account by the growth of saleable crops of any variety for which there may be a local demand; therefore by improving the staple and productive powers of the soil apart from ordinary manure, we at once widen our powers of production by enabling the land to carry a rotation of valuable crops, which in its ordinary state it would be useless to attempt. There is much land in various parts of the kingdom which tradition informs us was originally rabbit warrens. This is especially the case in Norfolk and Lincolnshire, and in some cases where the home farms possess such soils there is no reason why some land may not be again converted into rabbit warrens upon the new system, affording not only sport for the proprietor,

but also yielding an acreable return of profit equal to some of the best soils.

We propose to consider first the rotation of cropping for light chalk soils. We shall, however, find it necessary to make some distinction between those farms possessing irrigated meadows or useful pastures. We will therefore take first for example a farm having the advantage of meadows at the vale end, and we assume that the farm contain 550 acres, 50 acres consisting of pasture—viz., 25 acres of water meadow, and 25 acres of down or sheep walk on the hills; we then have the cropping of 500 acres to arrange. Our opinion is that a five-course rotation will be best, as it will carry more sheep than the four-course, to which we shall have to allude further on. The cropping will be—1st, Wheat; 2nd, roots and green crops; 3rd, Lent corn; 4th, Clover and grass; 5th, old field grass. We shall have first 100 acres of Wheat, half of which will be sown after Rape, Turnips, &c., fed off by sheep on the land; and the other half once ploughed out of old lea. In the next course we have to crop 100 acres with green crops and roots; 50 acres of this should be autumn-fallowed, taking the foulest land for the purpose, and this portion will then be ready in the spring for drilling with Mangold seed and Swede seed, for upon the exposed chalk hills the roots must be early to obtain full crops. The Mangold should not exceed 10 acres, leaving 40 acres for Swedes. On very thin poor land Mangold may be omitted and Swedes only grown. We have then 50 acres left for green crops, to be followed by roots, and this should be the cleanest land; but in the event of couch being present it should be forked-out to save time and tillage. About 10 acres of Rye may be sown for early feeding, 10 acres of early Trifolium, and 10 acres of second early Trifolium, and 20 acres of winter Vetches. All these crops should be fed off by sheep, except that perhaps a little green fodder may be required for horses, &c. Still the object is the manuring of the land by sheep, to enable it to produce a full crop where it is to be occupied with roots, and upon this poor land a liberal dressing of manure applied by the drill will also be necessary. The roots should be Swedes after the Rye, Hybrid Turnips after Trifolium, and Grey Stone Turnips after the Vetches, to be sown in divisions as fast as the land is cleared of the green crop.

The third course will consist of 100 acres of Lent corn. The question to be decided will be, What sort? Now, on very exposed aspects we recommend taking a crop of drege, but on the kinder soils and sheltered vales Barley will succeed. The reason for sowing drege is not only because the Oats will bear the bleak winds, but because when two sorts of grain are grown together there is a greater probability of obtaining a plant when attacked by wireworm, which on the soils we are referring to is the greatest enemy we have to fear. If 10 acres of Mangolds are grown these should be carted away, heaped, and covered secure for the winter upon old lea ground, because the land whereon they grow may then be sown early, and the fact of feeding them on the old lea will supply the sheep at a time when they would otherwise be feeding the Swedes on the land, which would delay the time of sowing the Barley or drege that may follow. It will at once be seen how desirable it is that the sheep-feeding should not delay the sowing of corn. In the next course we have 100 acres to be sown with Clovers and grass in the Lent corn; and in order that these should not become too gross and injure the corn at harvest time the seeds should not be sown until the corn is growing, about a month after sowing, and the seeds rolled in; the advantage of this is that the young plants will be more likely to avoid night frosts, and their growth somewhat delayed, and thus prevent their injuring the corn. We recommend the seeds to be sown as follows:—50 acres with Red Clover, Alsike Clover, and Giant Saintfoin, the object being to obtain two fall crops of hay for the sheep. The other 50 acres should be sown with Dutch Clover and Trefoil or Hop Clover, together with Perennial Rye Grass and Timothy Grass, as it will be entirely required for feeding with sheep. When the grass course comes round for seeding again at the end of five years the portion which was Clovers and Saintfoin should be reversed, and sowed with Dutch and grasses. In this way each will be likely to succeed better, because there will be nine years between the periods of growth.

In the fifth and last course we must bear in mind that we have to prepare for the succeeding Wheat crop, which is the first crop of the rotation. Having 50 acres of Clover and Saintfoin lea this should be reserved for sowing Wheat upon, previous to which it may be either cut for hay or fed with sheep, as circumstances and the seasons may render requisite. In the month of August the land may be dunged with farmyard manure and early ploughed in readiness for sowing with Wheat at the usual period. We have now to deal with 50 acres of old lea in grasses. This may be fed off by sheep, and on which the produce of 10 acres of Mangold will also be consumed up to midsummer, after which the land should

not be pared and burned, but ploughed and pressed, and sown with Turnips and Rape seed, with artificial manures, the roots fed off by sheep, and the land sown with Wheat.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—The horses have for some time past been unable to have upon the land under tillage as autumn fallow, but in those cases where the steam cultivator has been employed there has during several weeks previous to the 10th of September been much useful work done. As, however, the late rains came suddenly on the unfinished fallows in many cases the horses will be required on the first favourable opportunity to work out the grass and weeds, so that they may be dealt with on the surface, and be either burnt or carted away as the weather may permit. It is essential that in the event of the weather being adverse everything on the surface should be carted away to heap or laid out on the meadows, so that after Wheat-sowing is finished the land may be deeply ploughed and laid up for the winter months. No hindrance, however, need take place in the horse labour, for the manure from the yards, heaps, or cattle boxes may be laid out and spread upon the Clover leas, upon any dry land intended for Wheat and ploughed in, the late rains having softened the ground for ploughing and pressing. The land, also, where Turnips or Rape, &c., have been fed off by sheep will now be in good order for ploughing and sowing; for we like upon this preparation for Wheat to plough and drill the corn the same day, this being the surest plan to obtain the best seed bed, for as the season advances it will be found difficult after heavy rains to get the fallowed land in working condition if the seed time is delayed. Upon lea ground it is different, for rains settle the land down firmly and secure a good seed bed, especially upon any light soil. Upon any heavy soil it is often found best to secure a good seed time by sowing or drilling the land as fast as it is ploughed, any land being then more freely worked.

Hand Labour.—Men should now be employed in cutting off the bunches of grass upon the pastures, which may have been refused by the cattle and run up to seed stems, either with the scythe or the mowing machine. The cut grass should be raked up and carried away, because these grass stems often have ergot in the seed heads. Now, this is often the cause of abortion in dairy cows, and is sometimes a very serious matter, for when abortion commences in a herd of cows it cannot always be prevented from extending. We have also always been very particular in having the grasses and weeds cut off the banks and borders and carried away before seed heads were ripe, in order to prevent the formation of ergot, the effect of which is but little understood by many home farmers, or the insidious nature of the disease resulting in abortion. The men will still be employed in spreading dung. If the stubble Turnips, which have made great progress lately, should be considered worth hoeing, this work should be done if the weather is favourable, and if the land is dry enough the horse hoe and hand hoe may both be employed with advantage if the land is rich enough to give good Turnips, as these of a mild and open season will continue growing until Christmas. If the plants have not made much progress harrow or drag occasionally in suitable weather, and they will then, if thick enough, give in the spring a crop of greens, which may be valuable if fed off by sheep as a preparation for a crop of Mangold or drege corn.

As we have often advocated the building of ricks of corn or hay in the fields where grown, it will be necessary when the corn is thrashed to have the straw or haulm carefully ricked and thatched immediately, so that the straw, either required for fodder or otherwise, may be found dry and sweet when the cutting-out and carting to the home-stead is required. The low-lying meadows should now be trenched, so that the first heavy rains may drain away quickly. The water meadows, too, where they have been fed down sufficiently may now have all the mains and drawing trenches done out in order that they may be used at the first opportunity, thus taking advantage of the first flooding rains, which always carry a valuable sediment brought down from the high lands under tillage. The dairy cows should have some early Cabbages scattered over the pastures to supplement the grass, or else receive them in their stalls at milking time; but in the absence of Cabbages, and where but little arable land is under occupation, cotton cake may be given with great benefit to the cattle and advantage by manuring the grass land. When, however, cattle receive cake whilst feeding on the grass land it will always pay to employ a man or woman to spread the cattle droppings every few days, otherwise the benefit derived only makes the grass grow luxuriantly in bunches, which are refused by the cattle during the first year of growth. Horses, however, may be turned in to consume these bunches of grass in the absence of the cattle, but this does not affect the irregular action of this valuable manure, and which will certainly answer for spreading in some way. The chain harrow is sometimes used for the purpose. In buying in sheep stock it will still be necessary to obtain a written warranty of soundness, for in the grazing districts, where there is but little change of food for the animals, it is said that various flocks are still affected with the fluke rot. The purchase of sheep is still going on, and in the event of first-class Hampshire downs being required as well as the Dorset horned ewes for early lambing, if sought for, Weyhill fair in Hampshire, to be held on the 11th of October, is the best opportunity for obtaining the choicest stock. The crop of roots generally is so early and abundant

that it will be the means of forwarding in condition all the sheep stock as store animals, as well as those which are feeding for the butcher; but this plentiful supply of vegetable food should not induce the home farmer to give his ewes which are breeding any more than a very moderate allowance of Turnip, Cabbage, or other roots. Always when supplied the animals should run in the stubbles, Saintfoin, or old leas, as the change of diet is highly necessary; at the same time it is very important that the ewes should not be allowed to lie about on the Turnip fields like fattening stock but be moved for exercise, which is necessary.

ADVANTAGES OF A HOME FARM.—No. 3.

THE effect of the drainage of the whole of the grass land, a hundred acres in extent, has been an earlier stronger growth of grass in spring—a matter of the utmost importance for dairy cows as well as for the lean stock—a warmer drier surface, and herbage of a finer and more nutritious quality, which is of equal importance for the sheep, not only as affording them better food, but also as contributing in no slight degree to keeping them in a healthy condition. This last assertion may now be made with confidence after the severe test of last year.

MANURES FOR GRASS.

Beneficial as drainage undoubtedly is, it was only regarded as a primary step in the improvement of poor neglected grass land. Dressings of manure followed the drainage, and have been renewed annually so far as was possible and in every available form. Niceties of distinction between different kinds of manure cannot often be indulged in to any great extent, and I have been glad to use farmyard manure, lime mixed with road scrapings, wood ashes, soot, crushed bones, specially prepared mixtures termed "grass manure," and in point of fact any artificial manure except nitrate of soda, which is too exhausting for our thin light soil. Nor is the lime and soil mixture applied twice to the same meadow without an interval of a few seasons' dressings of farmyard manure and sheep folding, upon which lime so applied acts as a mild solvent, converting the humus more quickly into that soluble condition which it must assume before the rootlets can absorb it.

Bone dust, as it is offered in commerce, has not been used, but half-inch crushed bones containing a good deal of dust has been applied with excellent effect at the rate of 4 to 5 ewt. per acre. This dressing is regarded as a provision for the future rather than the present good of the grass. The dust is probably beneficial in the first season, but the decay of the bones is so slow that it is only after the lapse of two or three years that their beneficial effect becomes apparent, and continues so for a long time. It does not, therefore, prevent in any way the continuance of annual dressings of other manures. As much manure from the cattle yards as can be spared from the arable land is applied to the grass annually at the rate of forty cartloads to the acre. Especial care is taken to have this well decayed in heaps before it is used. A bed of roadside trimmings or any good soil is first spread upon the site of each heap; the manure is then carted from the yards, thrown in a compact heap upon the soil bed, and at once covered with more soil. After laying for about a month it is turned over, the soil mixed with it, and a little more fresh soil again thrown over it as a "fixer," to prevent the escape of its fertilising properties into the air. The plan is an old and simple one, answering well if done carefully, but if due care be not taken in covering with soil or ashes much loss of its richest parts in the form of gas ensues.

Sheep folding upon grass has also answered well. For this purpose I usually procure some full-mouthed ewes at the great September sheep fair at Lewes, and the folding begins in the last week of September. The sheep are allowed to run free in the day, and are only confined to the fold at night; the space enclosed is therefore not large, small folds changed twice a week answering best. The best guide to the size of a fold is the eye, for if it is found that the surface of the enclosure is not tolerably well covered with manure in three nights it is too large. As a rough guide for beginners a space 4 feet square per sheep may be given as enough. The food used in the fold consists of linseed cake, oats, and hay. This is given chiefly at night when the sheep are shut in, but they are never let out in the morning till they have had some hay. I experienced some trouble in getting this attended to, and at first actually found the fold opened on snowy mornings without any thought of feeding the hungry sheep! Some rock salt is always thrown about for the sheep near the fold. In about ten weeks we begin drafting off the best sheep for the butcher, and by the middle of February the folding is at an end. Full-mouthed South Down ewes so treated make excellent mutton, which is much liked by those who are fond of the high flavour that only comes with age. The beneficial effect of the folding is seen early in the following spring, the luxuriance of the dark green grass presenting a striking contrast to the surrounding

growth, which presents a comparatively dwarf starved appearance. —EDWARD LUCKHURST.

PAYMENT OF PRIZES AT POULTRY SHOWS.

FROM time to time complimentary letters appear in our columns and in those of our contemporaries upon the prompt payment of the prizes by the managers of this or that poultry show. Prompt settlement of all such accounts is highly desirable, and deserves commendation. The exceptional eulogies, however, which such cases evoke in some degree call attention to the fact that such promptitude is by no means general—we might almost say that it is rare. The show season is coming on, and there has not, as far as we are aware, of late been any special ease in which complaints of tardy payment have been heard; this therefore seems a fitting opportunity to say something on the subject. Had there lately been any outcry of clamorous creditors against some particular committee we should have hesitated to make what might have seemed personal observations. There may in particular cases be excuse or palliation for delay, and were such instances isolated we should not call attention to them. They are, however, common, and taken generally are a legitimate subject for criticism. We are not concerned with cases of real default. Of such we have of late heard nothing, but of habitual procrastination in sending out cheques and post-office orders for the prize money.

In most schedules a rule is formed to the effect that payment of entry fees must accompany the entries. Such a rule seems absolutely necessary for any proper and orderly system of accounts. We had always imagined that it was universally and rigorously carried out; but it has lately come to our knowledge that this is by no means the case. Numbers of exhibitors send entries without any fees at all, trusting to luck to win their amount in prizes; and, what is much more remarkable, such entries are commonly received. This is the result of an evil upon which we have frequently written—viz., the over-multiplication of shows, which makes it a hard matter now to make any show pay. Every entry is then of the greatest importance to the balance sheet, and secretaries do not refuse any. In one schedule lately sent to us the public are informed that this year entry fees must positively be paid beforehand, as last year a large number of them were never paid at all. This difficulty of prepayment surmounted, or rather we should say this folly of accepting entries without entrance money being discarded, there is hardly any undertaking of which all the receipts more certainly precede the disbursements than a poultry show; surely, then, there is no reason why the latter should so frequently be delayed for weeks and months. These delays have, as far as our experience goes, much increased of late. We do not remember having in former years been obliged so constantly to remind secretaries of their official debts. In some cases, and that too of no obscure or local shows, it would seem as if time was always given to the winners to forget their prizes. If they did so, or went abroad, or changed their residence, there would be so much gain to the show, or for somebody. If they send a reminder there is always a specious excuse for the delay ready; theirs is the only cheque delayed, or it has been lost in the post.

We do not for a moment forget that there are many admirably managed shows in which the accounts are kept as well as possible and prizes are paid with wonderful promptitude. The committees of some of them now advertise beforehand that the prize money has already been lodged in such-and-such a bank. This is an admirable plan by way of guarantee; it always gives confidence to the public and so increases entries. If the prizes are to be paid—and of course the managers of every good show intend that they shall be paid even at personal loss to themselves—it surely cannot involve any risk to them to pay down a few pounds each by way of guarantee before the exhibition takes place. There may be, however, places where previous experience of success warrants something being trusted to the sum paid at the door by visitors to the show; this, however, can be easily added up on the evening afterwards. All will then have been paid, and if its amount does not make both ends meet the promoters have to suffer. They will not suffer any the less by delaying a month or two about paying up; in all probability any show they may in future undertake will suffer the more from confidence lost.

We write chiefly in the interest of beginners, or at least of beginners in exhibiting. There are many ardent fanciers who love their birds, and breed good ones too, but who only exhibit now and then; they might certainly be encouraged to exhibit more. Trouble and vexation about the slow payment of prize and sale money often discourage them till they cease to exhibit altogether. Several such have complained to us that even sale money

is often long withheld, and we know their complaint to be true. Not long ago a lady fancier with superb birds was regretting that she could not sell them for half their value, as she had no name in the exhibiting world. We advised her to show them at one of the greatest shows with a moderate price upon them, where the public could easily see their merits for themselves, and would assuredly become purchasers. "Ah," was the reply, "I once did so; all shown were sold, but it was three months before I got the money, minus 10 per cent., which had been paid at the moment. I had rather take less and receive it at once without so much trouble." In the interest of such fanciers we call attention to the subject before the great shows come on, and, we are sure, none the less in the interest of the shows.—C.

VARIETIES.

THE BIRMINGHAM CATTLE AND POULTRY SHOW.—The prize lists for the forthcoming Show of cattle, sheep, pigs, roots, corn, and poultry, to be opened at Bingley Hall on Saturday, November 27th, under the auspices of the Birmingham Agricultural Exhibition Society, have been issued, and may be obtained, together with certificates of entry for the various departments, from Mr. J. B. Lythall, the Secretary. The Council have proceeded still further with their good work of encouraging early maturity by again reducing the limit to the age up to which the cattle can compete in most of the classes. They have also thought that the time has arrived when some of the larger prizes might be reduced, now that the animals can be shown both at Birmingham and Smithfield.

— **THE IRISH HARVEST.**—The Dublin correspondent of the *Daily Chronicle* sends the following review of the Irish harvest, made on excellent authority:—"The cereals are much superior both in quantity and quality to those of last year, while Potatoes, Turnips, and Mangolds are fourfold more productive and abundant. Hay is better saved, and more profitable and plentiful. Fruit also has generally proved a good crop, with the exception of Apples, which are almost a general failure, the early frosts having destroyed the blossoms. Peas, Beans, Cabbages, and all other vegetables have also yielded large and remunerative crops, although in some districts they were injured. It is a strange peculiarity of the year that Mushrooms are almost unknown. The yield of Wheat is so great that though the area under it is small the farmers' profits will be greater than when double the area was devoted to it. Its average yield is eight "barrels" to the acre against five last year. Of Oats the yield is from eleven to eighteen "barrels" per acre; last year it was only eight to ten. The yield of Barley is much greater than last year, and the grain is of sounder quality; but there is more than the average of small grain or screenings in each sheaf. The Potatoes are the best crop known since 1842, and the Champions are universally acknowledged as a boon to Irish agriculturists, having in almost every locality proved free from disease. There is as yet but a small proportion of them in the markets, the people endeavouring to keep them for seed. Flax was more sown this year in the south than hitherto, and the fibre has proved of such excellent quality that it will probably induce the farmers to invest more extensively in it; yet in the north it has not proved so satisfactory. The price this year is from 5s. 6d. to 8s. 6d. per stone, which is considerably less than that received last year. The most remarkable feature in this year's crop is the extraordinary yield of grass seed, which is not only an abundant one, but the seed is of such a good quality as to secure the high figure of from 15s. to 17s. per ewt. for perennial, and 11s. to 16s. for Italian."

— **THE AMERICAN GRAIN TRADE.**—Some idea of the grain trade with America may be gathered from the fact that in the month of August more than thirteen million bushels were shipped from New York alone, and that no fewer than 325 vessels were either wholly or partially engaged in the trade. The shipments for September were expected to exceed fifteen million bushels, and as the profits are about equally divided between the shipowner and the shipper the importance of the trade is apparent.

— **WHEAT SOWING.**—On all soils rich in manurial condition early sowing invariably produces the best results; it is also desirable on economical grounds, as effecting a saving of seed; and in the

case of Clover leys sufficient time should elapse between ploughing and sowing to allow the crude chemical constituents of the decaying vegetable matter to assume new and more useful forms, which may readily be assimilated without danger to the infant plant. In our extended wanderings during the autumn we were particularly impressed by the very differing appearance of the crops on land similarly situated as to soil and locality, and, as far as we can judge, equal in manurial condition. In the one case the straw was weak and puny, the ears short, clumsily set, and narrow-chested, three corns being the greatest breadth; and in some cases one of these was only partially developed, while in the other the straw was strong and reedy, ears long and broad, many having five corns in line. From information obtained on the different farms we visited we attribute the marked contrast in a great measure to a judicious selection and change of seed. We are fully persuaded that sufficient has not been directed hitherto to this important point. A few shillings spent at seed time may result in a gain of pounds at harvest. In making the selection it is essential that the stock should be obtained from an earlier soil and climate than that on which it is to be grown.—G. M. (in the *Agricultural Gazette*).

— **PITTING POTATOES.**—A correspondent of the same paper observes:—"Potatoes should be pitted never more than 3 feet wide at the bottom, and brought up to a sharp apex; Wheat straw at least 6 inches thick up the sides, and then another length of 3 inches in thickness spread crossways on the top. The sides of the pits should be earthed-up to within 4 inches of the top, so as to thoroughly bind down the straw laid crossways. It is advisable to allow the pits to remain thus for three weeks, and then complete the earthing-up. The Potato stems should be laid in heaps alongside the pits, to be ready for use during severe frost; by placing them outside the earth covering almost no frost can touch them. During long-continued frost we have seen it necessary to use rank stable manure."

— **AGRICULTURAL PROSPECTS.**—The fine weather of the past week has enabled the greater part of the outstanding grain to be secured, but here and there a field of Barley is to be found in stook. Progress has been made with the Bean crop, but a considerable proportion of it will require field room for another fortnight at least. The late Barleys are found to have been damaged and discoloured by the recent rains; and the entire crop of Barley, which is undoubtedly a good one, has been more or less injured by the storms which have occurred at intervals during the latter part of the summer. With the exception of a few favoured districts, and more generally in Scotland, the reports of the Wheat yield show that the effects of a wide-spread prevalence of mildew had not been taken sufficiently into account by those who expected better things; consequently there is much disappointment amongst outsiders and some farmers, that appearances should have proved deceptive. Farm work is now progressing very favourably, and should fine weather continue Wheat sowing will be commenced in good season on clays and stiff loams. The Pea and Bean stubbles, however, are not very clean. Stock now require assistance in the shape of artificial food. Northern markets have improved, but in the midland and southern counties the trade is slow for stores of all kinds.—(*Mark Lane Express*.)

— **GEESE IN IRELAND.**—Geese, says a daily contemporary, appear to thrive well everywhere in Ireland, and the trade in them between England and the sister island is rapidly increasing. A kind of poultry census was taken two or three years ago, when it was shown that in Munster alone there were over 800,000 head of Geese. Ulster had over half a million, Connaught had 483,000, and Leinster 440,000. Altogether there were in Ireland no fewer than about 2½ millions of these birds, which, reckoned to be worth not more than 3s. each in the market, represented some £337,500, much of this property being in the hands of those who are content to share their cabin accommodation with the anserine protégés.

— **FARMING.**—There are some people, says the "American Cultivator," who seem to believe that farming is an accomplishment likely to come as an inspiration, that anybody who has failed in mercantile or professional pursuits has only to buy himself a few acres of land, a moderate stock of farming implements, go through the easy routine of planting, and then wait in the shade of his own

Vine and Fig tree for an absolute and sure harvest. It is hardly necessary to state that only such men as have never tried farming take this view of it. Those who have made the experiment, whether they have been successful or not, will tell you that Nature, though a good mistress, needs much coaxing, and will not be wooed by proxy. The farmer's life, with all its boasted independence, has yet its many disappointments, and is made up of constant watchfulness. He must know the signs of the sky and be able to judge of the season's progress. He must know something, if only in a rough practical way, of botany, chemistry, meteorology; and more than all this, he must work—work with head and hands, work in all weather, whether he feels inclined or not, for weeds will not stop growing, nor crops cultivate themselves to humour his idleness. Only such farmers as will accept these conditions can be successful, and only such men give dignity to the agricultural interests.

FIXING FOUNDATION IN FRAMES.

BEING in Kent for a few days' holiday, myself and son went by train to Sevenoaks, and inquired for the residence of J. M. Hooker, Esq., which we found. Mr. Hooker was at home and took us to his apiary, where we had the pleasure of looking over several of his stocks of bees. They were in fair order, and the combs were beautifully straight, no curling at the corners, as some have said, happened in theirs; he told me that he had fixed the foundation (Raitt's) in the saw cut in the top bar, and kept it about a quarter of an inch from each end and about half an inch from the bottom, and the combs were worked out splendidly. There was no other means employed to keep them straight; they were simply hanging from the centre of the top bar, where they were held perfectly tight. We assisted in taking off sections and extracting the honey from one stock that had given over forty sections, and altogether we passed a very agreeable afternoon among his bees, which just suited—A WARWICKSHIRE BEE-KEEPER, *Weston, Leamington*.

TREATMENT OF FOUL-BROODY STOCK.

I FOUND some time since that one of my stocks (Ligurian) had foul brood. Before the disease appeared the bees had been fed with syrup medicated with salicylic acid. The diseased cells are so scattered among healthy brood that to cut them out would be to destroy the combs. The combs, &c., have been sprayed with salicylic acid solution without producing any apparent effect. I have two black stocks, each of which is perfectly healthy and very strong, as is the diseased one. All my hives, frames, &c., are new. I should mention that there are no bees kept within several miles of my apiary. What is the best course of treatment under the circumstances? Has the apparatus for the cure of foul brood, described in the report of a conversation of German bee-keepers, page 170, *Journal of Horticulture*, been tried in England, and if so what are the results?—OMEGA.

[At this advanced period I should advise, as the stock is very strong, that the bees be made into a swarm by shaking them from the combs on to a board upon which a propped-up skep stands. After twenty-four hours they might safely be transferred to a spare hive furnished with, say, six combs, to which they should now be confined for the winter. The brood in this way would be lost, but all chance of transference of contagion would be gained by the sacrifice. To save the brood the bees must for a time be separated, the queen going to the new hive while a detachment remains to act as nurses. When the outside air is low in temperature the considerable increase of surface brought about by division would cause, in my opinion, a greater diminution of vital energy and breeding power than could be compensated by the addition of all the bees obtainable by the hatching of the amount of brood the stock could now be supposed to possess.

It is during the breeding season that foul brood makes headway; and were it not that other stocks, your own and those of your neighbours, are likely to suffer from the continuance of the disease in their midst, we should rather counsel discontinuing feeding, and removing the brood combs as the bees hatch from them. These can either be destroyed or treated, as every diseased cell now declares itself. During the depth of winter all will remain *in statu quo*, and with returning spring you may find the stock free of disease. If, however, it should again manifest itself the weather will be in favour of your dealing with it.

I have used a home-made form of the German vaporiser in a case of undoubted foul brood which had made but very slight progress. The salicylic acid was put into a tinned iron vessel

somewhat like an ordinary retort with very short leading tube. The latter was passed through the opening in the quilt into the hive containing the whole of the combs, which were placed fully double the normal distance apart. The salicylic acid was vaporised by igniting methylated spirit in a small iron dish beneath the retort. In a short time the bees were returned to the combs and the operation repeated after a few days (about five). In addition all the grubs attacked were removed by a small stiff sable brush dipped in salicylic acid solution. The disease disappeared.

The only precaution seems to be rendered necessary by the inflammable character of salicylic vapour. It burns almost like olciant gas. The vapour as it enters the hive diffuses, and cools and condenses into minute crystals, which are wafted like dust moats into every crevice and cranny, and penetrate the whole hive in a manner much more complete than could be effected by spraying. The vaporised acid is extremely suffocating, and if inhaled causes slight chest pains for some time after.—F. CHESHIRE.]

COTTAGE BEE-KEEPING.—No. 6.

AFTER the lapse of several months I resume the subject of cottage bee-keeping where I left off. I brought my simple instructions up to a point which might well be postponed, as all I had left to say had chiefly to do with autumn preparations for coming winter.

If what I said in April has been attended to, all hives of bees intended to stand over as stock for the future will be now in first-rate order. After such a summer as we have had in these parts there cannot be a poor stock of bees that requires any considerable feeding; still, as these remarks may be read where the honey harvest has proved a failure, let me advise every bee-keeper who has any reasonable doubt as to the sufficiency of food in any of his hives to lose not a day in giving them what they require. For my own part I like to make assurance doubly sure, and always make a point of giving my hives all round a pint or so of strong syrup when the last warm days of the waning autumn are come. Then the bees will not have far to seek their food if any lengthened period of sharp frost should set in. How often does it happen that a hive well supplied with food in the remoter parts of the combs is found to have perished because the poor insects were too chilled to fetch it into their central nest? Now whatever is given them in late autumn is sure to be stored in their very midst.

As for modes of feeding, there are all sorts of ingenious devices in use, but none is simpler or better than top feeding over the central hole. Any kind of wide-necked bottle inverted over this hole will answer the purpose. A bit of lino should be tied over the mouth of the bottle, and then set the latter just over the hole with a bit of perforated zinc between it and the bottle. I hold a small jug or cup in my left hand, and invert the bottle into this first to catch any of the syrup which the sudden jerk may dislodge from the bottle, and when it ceases to drop it is quietly put over the hole. If there is no central hole at top of the hive (as in the case of the common skep) a deep soup plate full of syrup and covered thickly with straws can be set under the hive in a shallow eke of straw or hoop of wood, which must be the exact size of the skep. A pound of syrup or more can be thus given every evening after a warm day with the least possible trouble.

We are now come to the time when all extensive feeding should be in full operation; let not a day be lost. As for the supplementary feeding just referred to, it may be postponed to the last week in October, or even in mild situations till the beginning of November.

Let me again earnestly recommend a saving of all bee life by driving out the populations of all stocks that are going to be plundered, and joining them to the nearest stock to the right or left of where they stood. I gave full instructions how to do this last April (page 287), and need not repeat it here.

And now a few words about the wintering of hives. See that they are each and all thoroughly clean and dry, free from all cobwebs and woodlice, and warmly covered with any available material which will effectually keep off drip and damp. Hives are well wintered on their summer stands if proper care is taken to protect them from damp and high winds and the attack of their various enemies. None of the latter are more injurious than mice, and as these vermin can most easily enter any straw hive we have found in this one evil a sufficient reason for the disuse of straw; but care must be taken that all entrances to hives of straw or wood are so narrowed as to allow in the dead of winter for the passage of only half a dozen bees abreast of one another, say $1\frac{1}{2}$ inch wide and not more than three-eighths of an inch deep.

The other day I mentioned the case of a Dartmoor woman who plastered up her bees during twelve weeks or more from the latter part of December to the middle of March. Without exactly

following her example, which would be fatal in mild winters, I nevertheless shall take a hint from this good woman's practice, and I mean to prevent my bees from stirring abroad during all times of frost and snow and whenever cold and strong uncertain winds prevail. A simple block of wood the exact size of the entrance will be thrust in at dusk in the evening, with only a few tiny holes in the block covered with perforated zinc. Care, of course, must be taken to remove them on fine warm mornings at all times, and finally in the early spring according to the season. There are also many treacherous days during a continuance of stormy weather in March and even in early April, when they may be kept in for several days together, provided sufficient ventilation through perforated zinc is allowed them. At such times the loss of life in an apiary is very considerable. Thousands of bees have been blown away and chilled to death without a chance of their returning home. This accounts for the slow progress of hives in many a stormy spring time, and for the gradual dwindling away of many a weak stock, which could not nurture sufficient brood to make up for the daily loss of its population.

I need only add that bees are best let alone in winter. The quieter they are kept the better. All that is wanted is to look at the hives now and then to see that all is right. Meanwhile, the bee-owner can get ready for the coming season—making his hives, and putting all that are empty into a state of thorough cleanliness and repair.—B. & W.

THE HONEY SEASON IN SCOTLAND.

HAVING our bees home from the heather I am now in a position to inform your apiarian readers of the honey season in East Lothian. The year 1879 will be remembered by all bee-keepers as the most unfavourable that could occur. There were few if any skeps made as much honey as would keep themselves during the winter; in fact here we had to feed throughout the summer to keep the bees alive, and again to feed liberally this spring. Those who neglected to feed have lost the whole of their stock. Those who did feed have been well rewarded for the trouble and expense by a return from the Heather beyond the average of many years. A great number of supers have been secured, and the stock well supplied with honey besides.

This spring was not at all favourable for bees; though dry, it was often so cold that the bees could not work, and there was not much honey to be had from the flowers. At the end of June and in July we had a large supply of honeydew from the Pear trees on walls and from Oaks and Beeches, which gave a great impetus to breeding and made up the stocks with honey, but when it was stored in the supers it had to be taken out in many cases before they were sent to the Heather, its black colour injuring the sale of the Heather honey when mixed with it. Though the dark honey is good to the taste, we generally keep it here for feeding the bees in autumn and spring. Breeding had ceased in most of the hives before they left the Heather, as it had become rather cold. They are well stocked with bees, and most of them have begun breeding again since they were brought home owing to the fine warm weather we are getting. I don't expect more than 1s. 6d. per pound will be given to the bee-keeper for honeycomb in supers, the purchaser taking it away and selling it to the merchants. There is not much run honey sold here. Every endeavour is made to get them to put it into supers at from 10 lbs. to 15 lbs. of honeycomb in each; better prices are given for it in that way than in any other.—ALEXANDER SHEARER, *Yester Gardens, Haddington, N.B.*

OUR LETTER BOX.

Incubators (Chicken).—Write to Messrs. Thomas Christy & Co., 155, Fenchurch Street, London. Our "Poultry Book for the Many," price 6½d., post free, contains concise and reliable information on the different varieties of fowls and their management.

Fowls with Diseased Livers (S. P.).—The fowls are evidently suffering from disease of the liver, which at length kills them. This is often hereditary in poultry. Drive them out of the yard into the field. Keep them short of food, feed three times per day scantily. Let the fowl be ground oats or barley meal, slaked with water, and scattered abroad on the grass. Kill all the old diseased birds. Save the healthy and promising hens and pullets. Do away with all the cocks running with them, and turn in fresh ones in December. This disease often arises from overfeeding, especially with meal.

Spaces between Bars and Cover of Hives, &c. (Comber).—Half an inch space is decidedly too much to allow. A quarter of an inch is ample distance, as the only object of any space at all is to prevent crushing the bees when manipulating the bar-frames. The quilt will not inconvenience the bees, they simply avoid it. We have seen a quilt removed with hardly a bee upon it.

Keeping Honey (Idem).—Glass supers more or less filled with honeycomb will be best preserved by covering the mouth with a bladder or paper dabbed in white of egg—anything in short, that will keep the air from the contents. We have kept honeycomb in this way for a twelvemonth.

Pit for Stable Manure (T. C. A.).—There is no necessity for a tank for in the event of making a covered dung pit the liquid manure will be absorbed if led into it, and will prevent the dung from getting too dry, and with 8 or 10 inches of dry earth at the bottom the urine will be absorbed, and all may be taken out together. The pit may be made 12 feet wide, 15 feet long, and 3 feet deep, but it may be sloped off at one end for a cart to back into on the removal of the dung, &c. The covering may be of galvanised corrugated iron on pillars 7 feet up to the eaves, the covering to be 14 feet by 20 feet and spouted. The pit and covering may be made one-third less if the pit is cleaned out frequently.

Various (I. H.).—1st, In strong land pastures lying flat, if there are no small rushes amongst the grass, underground drains may do injury; only a surface trench or two would be sufficient. If, however, the strong land really requires covered drains, they should not be put in at a less depth than 3 feet and 2 rods apart, or perhaps placed at that depth, may answer by following the surface trenches if there are any, tiles not to be less than 2 inches in diameter. 2nd, Earth floors for horses if properly laid with dry screened earth rammed down with an iron-headed hammer will become nearly as hard as stone in a box where the horse is loose, and if the litter and dung are removed every day the earth will then last for years without renewal. If, however, the horse is tethered in a stall with earth floor properly rammed down on a dead level, or with a little fall towards the manger, the urine will then spread over the floor, and sink in equally over the surface, but the horses' shoes or feet will not disturb the surface; under any circumstances the earth in stalls will have to be removed when it is fully saturated and gives off offensive odours in the stable. 3rd, Concrete floors for cattle will do very well without litter, but better with litter; a pit behind the cattle with a sparrow floor over will take everything away without inconvenience if swept daily and strewed with gypsum, but earth or ashes should be placed in the pit every few days for absorption and for deodorising the manure. 4th, The thatcher's knife recommended is rather hook-shaped, and is used by them for cutting the eaves of thatch. A hay knife will not answer the purpose so well, unless the truss of straw is held down on a board to receive the edge of the knife after cutting through the straw. The articles in the Journal should be referred to for further details on these subjects.

REMARKS.

26th.—Very misty, canopy of cloud all day; calm and close.
 27th.—Hazy, good deal of cloud, but some bright sunshine in forenoon; calm and warm.
 28th.—Fog in morning, afternoon clearer with sunshine; fine evening.
 29th.—Misty early, fine bright warm day; misty again in evening and cooler.
 30th.—Fair calm day, with good deal of haze.
 1st.—Misty morning; fine bright day.
 2nd.—Early morning fine and bright, cloudy after 10 A.M., rain and wind after 3 P.M.
 Temperature very similar to the previous week, but the air damper, although there was little actual rain.—G. J. SYMONS.

COVENT GARDEN MARKET.—OCTOBER 6.

OUR market is now very quiet, prices remaining without any alteration. The supply of Pears from the Continent is short, though values are somewhat lower. There are large arrivals of American Apples this week.

A CHAPTER ON CHISWICK.

THERE is always something to be seen and learned in the Royal Horticultural Society's Gardens—something either new or useful—some hints or suggestions that may be profitably turned to account in other gardens; hence, without further preamble, I submit these notes.

DAHLIAS.—Worthy of notice at the present time is a trio of new Bouquet Dahlias, which are not only very distinct from other varieties in cultivation, but possess considerable decorative value. The first to notice is *A. F. Barron*, a bright clean sulphur-coloured flower, deepening to yellow in the centre. All the florets are quilled or incurved in the most regular manner, their interior being yellow, exterior sulphur. The flowers are about $2\frac{1}{2}$ inches in diameter, and being freely produced they have a fine contrasting effect with the foliage. *Deutscher Reich* is a remarkable flower, all the florets being distinctly three-lobed and slightly incurved. The prevailing colour is rich scarlet with a bronzy yellow under surface, which appears to stain through, and it shows very clearly on the point of each floret. The trio is completed by a variety named *Zogling*, a well-formed flower, peculiar by the outer florets being of a flesh pink colour, those in the centre being orange, imparting a novel appearance to the flower. These and some other varieties were sent to the Gardens by M. Deegen of Zurich. Although they do not possess the properties of high-class florists' flowers, they combine novelty with attractiveness, and are highly suitable for border decoration.

RICINUS DUCHESS OF EDINBURGH.—In a large bed on the lawn this *Ricinus* appears the best of several varieties on trial. The foliage is very dark, indeed precisely of the same colour as *P. Gibsoni*, but the plant is of larger and more stately growth than that variety, and for subtropical purposes is very effective.

HELIANTHUS ORGYALIS.—This old herbaceous plant grows 8 feet high and bears small clear yellow flowers. The foliage is very long, narrow, and drooping, and even when the plant is not flowering it has a very elegant appearance. As a bright late autumn flower for associating with shrubs by the side of carriage drives this species is worthy of notice. It is known also as *H. angustifolius*. It is a native of Carolina, and was introduced in 1789 by Thomas Watson.

AZALEAS.—A number of these valuable spring-flowering plants are in splendid condition, the result chiefly of their having been planted out during the summer in a bed of peat and leaf soil. They have recently been taken up and potted,

and have not "lost a leaf." Had they remained in pots all the summer it is not possible that they could be in their present satisfactory state. They were planted in a pit, and had the benefit of the glass lights for a short time, but throughout the summer the lights were removed night and day. A pit is no doubt an advantage, but planting out Azaleas in a prepared bed of soil in the open ground was practised with great success by Mr. Gower in the Tooting Nurseries, and there is little doubt that this Continental system might be adopted with excellent results in many gardens. The rich dark green insect-free foliage of the Chiswick plants, with the bold well-set flower buds, show conclusively the value of the mode of culture to which they have been subjected.

FRUIT.—This is nearly all gathered and stored in the capacious fruit room. Pears appear the most numerous, and are generally finer and cleaner than the Apples. There are a few very fine examples of the *Souvenir du Congrès* Pear that have been produced by a bush tree. The quality of the fruit is very good, but not quite equal to Williams' *Bon Chrétien* when in its best condition, and not equal, too, to another Pear about as large as *Souvenir du Congrès*—namely, *Vineuse*. In appearance this Pear is not attractive, but the quality is excellent—the best Pear in the room. *Beurré Hardy* is also now in season, the fruit being very juicy and possessing a honeyed sweetness. This Pear is a great favourite with small birds, which Mr. Barron states attack it persistently even before the fruit is ripe, and it is generally conceded that "birds are not bad judges of fruit."

The finest Apple in the fruit room is *Stirling Castle*, the grand symmetrically formed fruit showing with great prominence among perhaps a hundred other varieties on the central table. This is a kitchen Apple of great value, and for market purposes one of the best in cultivation. The most handsome Apple in the collection is perhaps *Uellner's Golden Reinette*, a fruit of medium size and in shape faultless. It is a dessert Apple of the King of the Pippins type, equal in quality, but much superior in appearance to that useful variety. *Cellini*, a free-bearing variety of good appearance and quality, is also represented by some excellent specimens. For home use this Apple is highly worthy of cultivation, but is less valuable for market purposes, as it is not a good traveller, showing as it does its bruises so prominently. It is a culinary Apple of the first quality, and "not bad" for dessert. Among the dessert Apples *Lucombe's Pine Apple* is attractive in appearance and of excellent quality when ripe during November and December; and there are good examples of a later, very distinct, and good variety, *Court Pendu Plat*. The flowers of this variety are late in expanding, and often thus escape the frosts of spring—a circumstance of some importance. The few Apples named may safely be included in all collections.

GRAPES.—In the large curvilinear vinery the crop is good. The berries are, perhaps, not quite so large as those of the crop of last year, but large enough to command the highest price in the market. Some of the Vines were prematurely defoliated by a sudden and severe frost last November, but they have not suffered to such an extent as might have been expected; some, indeed, do not appear to have suffered at all, while only on one or two is the injury they received apparent now. This proves pretty conclusively that those who are so unfortunate as to have mealy bug on their Vine leaves may remove them as soon as they assume their decided autumnal

tint, and thus remove a great number of the insects, instead of permitting the leaves to fall and the insects be left in the house. When the frost destroyed the leaves of the Vines in question they were quite green. The reason of the berries being so large last year was doubtless the result of the heavy rains of the summer and autumn. It is easy to water and mulch Vine borders, and those at Chiswick are liberally treated in this respect, but the majority of the roots of healthy octogenarian Vines are probably outside the border and extend to a great distance, and only the rains can give them adequate support. The fine Grapes of last year especially, and also this, prove to demonstration that Vines enjoy large supplies of water when the soil is well drained.

The young Vines planted last year in the long corridor have been more than once spoken of approvingly, and not a word too much has been said in their favour. They are in the most satisfactory condition; the fruit of Alicante is superb, and of Gros Colman very good; but the slight shanking of the latter on two or three Vines is a puzzle to all who inspect the house. There are a few Vines of Alnwick Seedling in this house that teach a lesson that cannot be too widely known. On every Vine of the other varieties the bunches are full and berries regular, half of those that set and more having been cut out. On every Vine of Alnwick Seedling the berries have failed to set. There is not a bunch "fit to be seen." All had precisely the same treatment, no artificial means having been resorted to in distributing the pollen. No doubt Mr. Barron could have produced a different result had he so desired, but he wisely left the bunches to share the ordinary natural treatment that suited the other varieties so well. He considers the Grape a valuable one, but it requires artificial aid in setting, and is worthy of it. Such aid, according to a report of his garden in the Journal, Mr. Bell of Clive House, who grows this variety so well, gives by an artificial distribution of pollen. It is important that this requirement of what is a valuable acquisition to late Grapes should be widely known, as many people have planted Alnwick Seedling who are not acquainted with its shy-setting character. At Syon House two Vines of it are fruiting, one having been received direct from Clive House. Both have set sufficient berries, but there were none to thin out. The results at Chiswick suggest the treatment that is requisite to have this fine Grape in satisfactory condition.

It may be mentioned that the remarkable condition of the Vines in this house is not due to an elaborately prepared border. Peach trees had been grown in the house for a number of years, and all that was done before planting the Vines was to spread 5 or 6 inches of fresh loam on the border, a little manure, and a sprinkling of half-inch bones, and trench to the depth of 2 feet. The Chiswick soil is evidently well suited for Vines, and had £100 been expended in making the border these young Vines could not have been in better condition than they are now.

VEGETABLES.—The largest space this year is devoted to Brussels Sprouts, which are grown from seed supplied by various firms. Probably all or nearly all the varieties, "strains," and "selections" in cultivation are represented. In due time, I presume, they will be officially examined and reported on, and it is not necessary to say more at present than that the plants generally are not buttoning well. This is not solely from any inherent fault possessed by the varieties, but the heavy rains following the dry period of August and September appeared to have forced the plants into a late and luxuriant growth, much resembling that of spring, when the tops commence elongating, and the side growths assume the open character of rosettes. Of Brussels Sprouts generally it may be said they cannot be grown in portions too open and exposed, overcrowding and anything in the form of shelter militating against the production of firm sound knobs.

The Egyptian Turnip-rooted Beet.—This Beet has lately been referred to in the Journal. It is grown largely at Chiswick with some of the long-rooted varieties. In quality the Turnip-rooted is the best of all, being the sweetest and most delicately flavoured, but some of the roots are not very deep in colour. By selecting roots of the best colour for seed-growing, produce of a uniform deep red might soon be insured. This is also the most productive of Beet, a greater weight of

roots of uniform and useable size being obtained from a given space than any other variety; and it probably exhausts the soil less than the stronger and deep-rooting varieties. The Egyptian or Turnip-rooted Beet possesses advantages not sufficiently recognised, hence this word in its favour.

Early Munich Turnip.—Early Turnips cannot be had too quickly in the spring. The variety named is decidedly the earliest of all. It is small, red, and flattish in outline. Grown by the side of all the approved varieties its precocity is apparent. For forcing, and the earliest crops in the open garden, it can scarcely fail to be useful, and in due time to become popular. It will no doubt shortly be included in all seedsmen's lists, and it is not unlikely that it will retain a position there for some time, which is more than can be said of all new vegetables.

COMPOSTS.—In one of the houses was a large heap of turfy loam, containing a liberal admixture of horn shavings. The fancy name for this fertiliser is, I think, Buffalo horn Manure. It was mixed like snowflakes in the soil, and the compost is found of great value for fruit trees in pots—indeed for all plants requiring generous food. The horn manure is a safe ingredient for mixing with soils, and its effects are quickly apparent, and at the same time long-lasting on the trees and plants to which it is applied. A heap of wood ashes may appear to some a very simple matter to allude to, but if it is worthy of having a place under glass at Chiswick it is worthy of being mentioned here. The value of a store of well-burnt garden refuse cannot be too strongly urged on all cultivators. At Chiswick all rubbish that can be burnt is submitted to the action of fire, and the residue is of great value. For Vines there is no better ingredient than wood ashes; for mixing with soil for plants generally it never fails to act beneficially, and for placing in drills and covering seed in the garden it has no equal for inducing free germination and promoting a healthy growth of the seedlings. If there are any who think a heap of wood ashes a mere trifle to dwell on, they may be reminded that those who attend to trifles of this nature are precisely those who achieve success; and, as a great man once observed, "Success is no trifle."—VISITOR.

THE ROSE ELECTION.

TEAS AND NOISETTES.

EVEN the great apostles of temperance must be delighted when they hear admirers of "the cup that cheers," and unfortunately often does the other thing, exclaim, "Well, after all there is nought so refreshing as a cup of tea!" And what says the Rose enthusiast to his special Tea? Is he the one whit behindhand in love for and admiration of the Rose Tea? I trow not. And truly, do we desire to see the queen of the parterre in her grandest attire, it is when she produces a really first-class exhibition bloom of these varieties. Not only is this production a beautiful sight for the eye to feast on, but the perfume of the Tea Rose is delicious and refreshing. Further, how tenaciously do these forms of our favourite flower retain their glories! how reluctantly do they yield them up! Here certainly, in this particular, the Perpetuals must hide their diminished heads. How rarely in them does the beauty of the day of gathering last to the following day! How few, if any, have ever dared to face the scrutinising glances of a judge at two succeeding exhibitions!

There is little question that were Teas and Noisettes better able to resist the influences of our somewhat ungenial climate they would be greater favourites than they now are; but they well repay the extra care bestowed upon them, and where tended carefully are often beautiful bloomers early and late. I have cut several very respectable blooms of Gloire de Dijon from a tree trained on a wall on the 1st of January, whilst a plant of Safrano that was in a corner of the garden in one of my former resting places often gave me many of its lovely buds before the Perpetuals were showing the faintest prospect of a future harvest.

In the present election the voters were not only limited to Teas and Noisettes, but they were also limited to general purposes. Practically, it seems to me, that you thus get really at the best varieties for general use. Each voter answers according to his own view, whether exhibition or garden; but the whole result shows us what are the most generally useful varieties. Anyway, I think all will agree that most of our best sorts are to be found in the first two dozen on our list, whilst the Roses that head respectively the thirty-six and the twenty-four polls are gems of

the purest water. The cream of these varieties has certainly floated to the surface.

In the thirty-six varieties poll Catherine Mermet heads the list, bearing out the remarks of one of the voters, who adds in a note enclosing his list, "I think Catherine Mermet quite the best Tea; it is excellent in every way, and hardly a bloom is produced that is not fit to show." Personally I would almost endorse his opinion were I not so devoted to the queen of the twenty-four varieties poll—Souvenir d'un Ami. Both are exquisite specimens, both fairly hardy, whilst a good bloom of either would be a great addition to any stand of any dimensions.

Only to new friends is it necessary to explain our table. The first column denotes the position of the Rose on the poll; then follows the name of the Rose, its character, raiser's name and the year of its introduction. Blanks occur here which I am unable to fill up; but I would here express my thanks to Mr. H. Curtis of Torquay for his kind assistance in supplementing many of my omissions. Then follow the columns A, B, and C, representing the number of first, second, and third-class votes each Rose has obtained, the simple letters being the amateur, and those with the asterisk the votes of nurserymen; the last column being the number of votes polled by all the voters collectively. Two Roses having an equal number of votes have their position settled by the number of first-class or second-class votes; if still equal they are bracketed together.

The following table represents the thirty-six varieties election:—

No.	Name of Rose.	Charac-ter. Age.	Raiser's Name.	Ama-teurs.			Total.	Nurse-rymen.			Total.	Grand Total.
				A	B	C		A*	B*	C*

* These Roses I find with both names, being in one place attributed to one raiser, in others to the other.

In all 120 Roses have been named by twenty-eight voters. Besides those tabulated, five other Roses obtained five votes; eight mustered four votes each; nine secured three mentions; thirteen have only two votes; and the honour of solitary notice is enjoyed by no fewer than thirty-three Roses out of 120; in round numbers one in five only received a solitary recommendation.

It will be seen that in this portion of the election the number of amateur voters and nurserymen are the same—fourteen in each; and the different value placed upon the Roses by the two different classes of growers is very interesting. Let us mark, for example, how amateurs appear to esteem Madame Berard, Jean Pernet, Perle de Lyon, Bouquet and Boule d'Or much more than the nurserymen do; while, on the other hand, the latter show a marked preference for Madame de St. Joseph, Isabella Sprunt, Safrano, and Céline Forestier. On the other hand, Triomphe de Rennes, Marie Guillot, and Moiré have the same number of votes from each class, and in the former the value of each vote is almost identical.

There is another point of great interest in the Teas, and that is their antiquity. The Hybrid Perpetuals are comparatively recent; few, very few, of those that have been tabulated in the election lists can go back twenty years. On the other hand, look at our present list. Out of fifty-two tabulated varieties nineteen are over twenty years of age, ten are over thirty years, and several are over forty years old. Indeed, if there were Rose exhibitions thirty years ago the Teas must have had it all their own way for beauty, the H.P.'s of that date being very third-rate according to our present notions. Often we complain of our H.P.'s being too thin. There are many blooms even of so grand a Rose as Charles Lefebvre that one would like to see with just a few more petals, but in the Teas it is often a complaint in the other direction—too much stuff, and under a breath of unfavourable times a somewhat churlish retort, "Well, then, I just won't open." Alas! this is too often the case. "Tis sad, 'tis pity; and pity 'tis, 'tis true."

The names of those who have kindly replied are these amateurs—Revs. H. B. Biron, E. P. Wellings, G. P. Hawtrey, and C. H. Bulmer; Messrs. I. T. Strange, W. Mount, J. H. Arkwright, Alfred Evans, W. Corp, J. Mayo, T. Laxton, Geo. Baker, Joseph H. Pemberton, and a lady, "A. M." Those of the trade to whom we are all indebted for their opinions are Messrs. Cranston & Co., George Paul, Keynes & Co., Curtis & Co., C. Turner, Davison and Co., George Prince, Rumsey, H. Merryweather, Ewing & Co., Mack & Son, Francis & Co., John Mattock, and Thos. Bunyard.

To all of these helpers I tender my grateful thanks. Next week I hope to give the twenty-four varieties poll, and to add also a list from our friend Mr. Ellwanger of New York for comparison.—JOSEPH HINTON, *Warminster*.

OLD v. GILBERT'S VICTORY OF BATH MELON.

ALL who have grown Gilbert's Victory of Bath Melon were, I should imagine, rather puzzled at the description given of it by such a practical man as we have every reason to believe Mr. Pettigrew to be. What he really described on page 326 was Gilbert's Netted Victory, and this he has confounded with the "improved" form of Victory of Bath, for which Mr. Gilbert is also accredited. When I first received the Netted Victory I was very much in hopes that it would be a netted, and, therefore, a really improved form of Victory of Bath. This was, I must admit, altogether supposition, as there was nothing to encourage the idea on the seed packet; and if Mr. Pettigrew still has his original packet, he, doubtless, also will find this to be the case. At the same time the name selected is misleading, and has had the effect, I believe, of causing many to be prejudiced against what is really a well-flavoured and very distinct Melon.

With regard to the identity of the two older varieties I may mention, that having also noticed the remarks on page 292, I alluded to them in my correspondence with an extensive and skilful Melon grower, who is also what but few gardeners are—a great Melon eater. He says there is a "very great difference," and that "Gilbert's are not such good doers; the fruit are smaller, with shorter footstalks, and the rind thicker than is the case with the old Victory of Bath. The latter is also nicely netted when well grown, but although of better flavour in the first instance, the fruit does not keep good so long after being cut as does Gilbert's variety." This to a certain extent agrees with Mr. Pettigrew's description of the old variety.—W. IGGULDEN.

FUNGI A RESULT, NOT A CAUSE OF DISEASE.

"It is a singular fact that fungus is so often said to cause disease. The Potato disease has repeatedly been attributed to it, so has Peach blister, and now we are told that it gives rise to the shanking of Grapes. In every instance the idea is erroneous." I have copied the foregoing from the beginning of my note on page 206, in order to make it quite plain to "S." that my statement was only "general" so far as it refers to these three forms of disease, and not by any means so sweeping or comprehensive as he appears to suppose. As to what I have advanced being merely "the unsupported opinion of one individual," the note of "AN

INTERLOPER," on page 333, will serve to convince "S." that I am not quite alone in my views. This attempt to show that it is the action of the mycelium which causes the leaf-discoloration is quite worthless because he gives no reason for it. Long and close observation enables me to say positively that the disease never attacks the foliage till its legitimate functions are ended; and I may usefully inquire of our "fungologist" why the fungus does not attack the foliage till, as I once more assert, it has ceased growing and incipient decay has begun? Will "S." kindly give his authority for the statement that *Peronospora infestans* was unknown in this country before 1845?

From the example of Peach blister in a well-sheltered garden to which "S." alludes, I am afraid he is not a very close observer, or he would be aware how worthless are all ordinary forms of shelter to screen the tender foliage from the high north-eastern wind which sweeps over trees and walls around hills and corners in the most tantalising manner. Let me give an instance of this from my own practice, for I have plenty of them, enough perhaps to convince even my sceptical opponent. Some eight or nine years ago I planted a fine vigorous young tree of Dr. Hogg Peach against a south wall near the west end of a vinery, thinking then, as "S." does now, that such a sheltered nook would suffice for its protection. It grew freely enough and in due course filled its allotted space, but every spring it was so badly blistered that its spring growth was crippled, and not one dish of good fruit could I gather from it. At length it was decided to cover this particular length of wall with a glass lean-to house. Then what a change came o'er the scene! I could exclude the cold spring winds, and blister vanished never to return. Ever since then the Dr. Hogg, in common with the other Peach trees in the house, has continued in perfect health and yielded an annual crop of its delicious high-coloured fruit. At the present time no tree could be in a more flourishing condition, and I may confidently point to it as one of many reasons for my "positive assurance" in this matter. As to Mr. Taylor's trees, it would be rash to attempt an explanation without knowing the conditions under which they were exposed more fully, but I should be disposed to say that they were what I long ago termed hardy varieties; for there are undoubtedly some sorts of Peaches and Nectarines that are much less tender than others, and it was the discovery of this important fact which induced me to beg raisers of new varieties to select those that had been found not to blister for cross-breeding, in view of obtaining a still more hardy strain of these popular fruits.—EDWARD LUCKHURST.

FLORISTS' FLOWERS.

AURICULAS.—These might now be in their winter quarters. Mine have been there for a fortnight, but in ordinary seasons the second week in October is time enough. Care should be taken that slugs do not harbour themselves in or about the pots, and if any traces of them are found they should be carefully hunted for at night. Green fly should be brushed off and all dead leaves removed. It is not well to remove leaves, even the yellow, until they are flaccid. I have had but little autumn blooming on my plants. This I in a great measure attribute to their having been potted very late, later than I ever recollect doing them before. They will now require very little water. Coverings should be ready in case severe weather comes on. Cleanliness and a dry atmosphere are the chief points to be secured at this season.

CARNATIONS AND PICOTEES.—This has been a very favourable season for the layering of these beautiful flowers. Layers when well rooted should now be taken off and potted either singly or a pair in a pot. Where they are grown in beds the beds should now be prepared and planted, but not until the ground is dry and in good condition; these heavy and continuous rains will prevent this being done at present.

RANUNCULUS.—The Turban varieties hardly come under the designation of florists' flowers, but they make a very fine display in the spring months. They ought to be largely grown. The white variety Hercules, and an edged flower, Commodore Napier, more like a Persian variety, but very hardy, ought to have a place with the brilliant scarlet.

GLADIOLUS.—It will soon be time to lift the corms; indeed the smaller seedlings may be lifted at once, and the general collection towards the end of the month. I know of no better plan of wintering them than placing them singly on shelves, placing the base in dry sand. This, I think, prevents them from drying up so much as when placed on wooden shelves only. Unquestionably if the corms come much into contact with one another they encourage the emission of roots, which cannot be good for the future well-doing of the corms. I hope, in giving some account of my garden experiences during 1880, to give, as your correspondent suggests, a list of the newer varieties which I consider worth cul-

tivating, for some excellent varieties have been added to our lists both at home and abroad.—D., Deal.

THE INTERNATIONAL POTATO SHOW.

IN a communication in the *Journal of Horticulture* of September 30th "A GARDENER" comments on the Show generally, and criticises the twenty-four dishes of Potatoes staged from here. Your correspondent refers to two dishes of Potatoes, the first White Emperor. This lot of Potatoes was, in my opinion, without doubt White Emperor, but in this exceptional season larger than usual, and showing discoloration, because being large the tubers were forced nearer to the surface than others. Shape in tubers goes for nothing; scores resemble each other exactly, but differ only in colour or markings. White Emperor is just like Blanchard in form and outline, as it is like many other rounds. I had no reason, let alone desire, to put up a dish of anything that was not true to name. In staging the twenty-four dishes the White Emperor was the last; and before finally deciding I submitted to my brother, who helped me to stage dishes of Rector of Woodstock, Porter's Excelsior, and Woodstock Kidney, and he thought White Emperor the best. Does that look as if an impropriety was intended? Further, I had left after staging all the collections ten spare dishes of various kinds, so it is not necessary to say more on that point.

Early Ohio is next referred to. Why does not your correspondent lay the fault of the remarkable similarity of sorts at the doors of the raisers rather than at the feet of the growers? Early Ohio is of the Beauty of Hebron family, but has dwarfier haulm, and the average type is rounder. My stock came to me through Mr. Lye, who had it from Mr. Quincey of Peterborough, and I have found that it produces handsome tubers. I was enabled to select when lifted a larger proportion of sample tubers than from the Beauty of Hebron. I regard the Early Ohio as not only fine in appearance, but I have found on cooking it that it was with me quite before any others of the Early Rose type in quality. It was because of these features I was so anxious to show it in the collection.

In dealing with the seedling Potatoes "A GARDENER" speaks disparagingly of our Lord Mayor as having rather deep eyes. That is incorrect. It is not deep-eyed, and it is fine and handsome; furthermore, it is as Mr. McKinlay, who came down here to see it lifted can prove, a wonderful cropper, whilst its quality is first-rate. It is the product of a cross between the Early Rose and Fenn's Early Market.

In another respect your correspondent's notes are not quite accurate—namely, in the varieties that were largely shown, and in the best condition. In white kinds he includes Jackson's Kidney, though shown in only two or three collections; Pride of America, which is but another Snowflake, and Yorkshire Hero and Edgcott Seedling, both being Lapstones. Surely Magnum Bonum and King of Potatoes might have been included in the list. In red Kidneys Mr. Bresee was shown only in three dishes, and Defiance about the same; both are very fine and handsome I admit, but it is not correct to class them as being "largely shown." In coloured rounds he omits one found in almost every collection—Radstock Beauty, whilst Fenn's Cricket Ball has never been sent out and never will be.

Another critic, Mr. J. Muir, takes exception to the cooking qualities of certain Potatoes named by him. It is curious, but none the less true, that very many growers have written in high terms of the quality of Beauty of Hebron, Snowflake, American Purple, Climax, and Early Vermont. Does not this show, that if not in Wales at least elsewhere, these Potatoes may be good. I can but say that here they are all very excellent. May we never have to eat worse. In criticising quality, however, it must be borne in mind that many varieties have been sent into commerce that have given large crops with little or no disease. When those varieties Mr. Muir so much praises give one-half or two-thirds diseased tubers, as has been the case in previous years, we cannot afford to be too nice as to quality. Yet the less raisers do not forget the element of quality, but they have always had to contend with this obstruction, the higher the tuber quality the greater the proportion of disease. As to Mr. Muir's stricture upon the donor of the prizes for the best-coloured kidney entering for the same, the responsibility is mine and not that of my brother, Mr. R. Dean. The object of that, as other classes, was to bring out the best representative of the section that could be found. I believed Mr. Bresee, the new red kidney, to be the best, and staged it; the winning of the cash was of the smallest moment.—ALEXANDER DEAN, Bedford.

THE JAMAICA HURRICANE AND THE BOTANIC GARDENS.—A letter from Mr. D. Morris, published in *Nature* of the 7th inst.,

thus describes the effects of the recent hurricane last month:—"At the Cinchona plantation, besides damage to buildings and sheds of about £650, nurseries and seed beds have suffered so much as to reduce the stock of available seedlings from something like 500,000 down to 80,000. At the plantations vegetation is so literally swept away that only here and there can we see a standing tree. There is not a leaf left on either the indigenous or Cinchona trees. After a careful inspection we have estimated that 20,000 Cinchona trees of all ages have been uprooted, or so severely damaged that they must be immediately barked. Out of the small garden at Castleton, covering only about 5 or 6 acres, fifty-five trees were destroyed, and ninety-eight severely injured. Out of the trees severely injured—i.e., probably blown quite down and put up again with trimmed limbs and supports, I found the Para-rubber Mangosteen, Tonquin Bean, Cam Wood, Olive, Cinnamon, Nutmeg, East Indian Mango, Chocolate, Liberian Coffee, &c. Even if they live we shall get no fruit from them during the next season, and we shall be unable to supply plants in great demand for some time. The Parade Garden, Kingston, felt the hurricane greatly, but as we had nothing there except ornamental trees and shrubs, we hope to recover our losses soon. The Cocoa Nut plantation at the Palisadoes had sixty-one bearing trees blown down, and forty-one rather young ones just coming into bearing. The Old Bath Garden has also shared in the general injury. The fine old Cinnamon Tree, the Camphor Tree, and the Pinus are down. The King's House Gardens and grounds have fortunately escaped much injury."

TUBEROUS BEGONIAS AS BEDDING PLANTS.

I HAVE not known the value of the Tuberous Begonia as a bedding plant until this summer. Having been successful I trust a few cultural notes will not be out of place in your valuable Journal. During the season the Begonias in my estimation have far surpassed the scarlet Pelargoniums in general effect, and now (October 6th) there is not a bloom on the Pelargonium, yet the Begonias are as gay as at any time during the summer. All the plants bedded out were raised from seed sown on September the 2nd, 1879, and January 2nd, 1880. I find no advantage from sowing in the autumn, as the plants thus obtained lose their leaves and rest for six or seven weeks, whereas those from the January sowing have grown on without rest, and were when planted out (June 8th) quite as strong and forward as those from the September sowing. My mode of culture is to sow in heat early in January, and when the seedlings are large enough prick them off into pans or boxes 2 inches apart, let them remain in heat until the beginning of May, when they may be gradually hardened off and planted out at the beginning of June.

The chief secret of success is, after the seed is sown never allow the soil to become dry, and keep all insects from the young plants, for if allowed to become infested with aphides the plants will never thrive until that pest is destroyed by the usual means. If the summer is hot and dry the beds must have copious supplies of water, as I find the plants are very impatient of drought. I strongly recommend the best varieties for pot culture, but for bedding purposes the more common drooping varieties are most suitable. If the old plants are required for another year they can be lifted and kept similarly to Dahlias, but they should be potted as soon as growth commences in the spring. I may mention that we place the plants in the beds about 6 to 8 inches apart, as in that case they help to support each other.—JAS. CHILD, *Garbrand Hall*.

TWO KENTISH GARDENS.

NOT grand show places—not places presided over by a grand gardener versed in all the "ologies," and doing everything on scientific principles—not gardens resplendent in all the glories of bedding-out and carpeting on the most approved or most fantastic principles—but gardens which owe their origin and their present beauty to the loving care of the owners, who have brought to their creation the culture of well-stored minds, of an intelligent sense of real beauty, and of a most thoroughly artistic taste; where at every step you see some novel feature, some glimpse of real beauty; where, not as in some gardens, a few minutes enables you to take in the whole at a glance; but where for a long day you might delight yourself with the varied efforts of thorough taste and love of Nature in her best and brightest moods. These are the gardens of which I would now write; and when I say that one of them is that of Mr. Harrison Weir, all who know him or who have had the pleasure of reading his many contributions to the Journal, will at once be ready to believe that I write in no spirit of exaggeration.

It was on one of those lovely September days with which we have been lately favoured that I accepted the oft-repeated invitation of my excellent friend Mr. Harrison Weir, a name so dear to all who love animals, and especially to the boys and girls of England who have rejoiced over his loving sketches of their pets. The invitation was accompanied by a message from Major Horrocks that I would visit him on my way, and in these two gardens I saw much that would delight any lover of a garden, and where I learned much of interest and value to horticulture, and which I should be glad if I could convey even a portion of to my readers. No two gardens could possibly be more distinct, although they are both guided by the same spirit. One is on a dead level, where all the effects are due to art; the other stands on a lovely hill, whose undulations have done much for it, and whose surroundings are those of real woodland beauty. And although I can give but a very imperfect idea of them both, yet I may perhaps interest some of my readers and encourage others who imagine that unless their gardens are favourably placed by Nature it is vain to attempt to make a beautiful garden.

Mascalls, the residence of Major Horrocks, is situated in the parish of Brenchley (where, by-the-by, *Gladiolus brenchleyensis* was raised), about a mile from the Paddock Wood station of the South-Eastern Railway. The house is an admirable adaptation of an old-fashioned farmhouse to the requirements of modern life. The character of the house has been retained, and the additions which have been made to it have been most judiciously effected. A very handsome dining-room and other rooms have been built at the back, but the front of the house retains quite its old character. When, thirteen years ago, it came into the possession of its present owner, it was simply a flat field with only a few trees on it; and although farm and orchard had been well looked after, gardening had been little thought about. Major Horrocks' first interview with the gardener, who has been some forty years on the place, was not encouraging. "There, I don't want you to come here a meddling with me!" was the response to some observations he had made; and yet this rough diamond has proved a veritable gem, with an excellent eye for colour, arrangement, and form, and has been a most valuable assistant to his master in carrying out his plans. The first question to be decided was, of course, how to lay it out. The high road ran at the bottom about a furlong off. This must be planted out, the space between must be arranged: but how? Ordinary gardeners would have said, and friends did advise, placing a number of flower beds close by the house, on which to look from the windows. Not so thought Major Horrocks. He pushed all his beds into the distance, and had a wide expanse of lawn before the house. By this means the view is not shut in, air and light are about the house, and the eye rests on the shrubs and beds on the distant part of the lawn.

On entering the place from the road we are at once arrested by a bed on which were four fine plants of *Brugmansia suaveolens*, 6 feet high, and most conspicuous by their fine foliage and lovely white flowers. Then on this same side of the house, from whence there is not, nor can be, any view, there is a very remarkable piece of rockwork, on which are planted a large number of the best varieties of Sedums and Saxifrages; and plunged in their pots amongst these very profusely a large number of remarkable succulents, Cacti, Azaleas, &c., which make, combined with one or two other plants interspersed here and there, a very remarkable bed. On the side of the drive up to the house one Agave was planted singly in small beds surrounded with *Cerastium* or other small bedding plants; while on the side of the house *Abutilons*, *Clematises*, and many handsome plants contributed to hide bare walls and to add colour and beauty to the scene. In a shed close by I saw two large plants of *Camellias* which, owing to some freak, were now in full bloom to the great disappointment of the owner.

As it would be impossible for me to give in detail the various combinations which Major Horrocks has made to give beauty of outline and colour to his gardens, I will just note one bed which I have called the Artichoke bed. In the centre of the bed there is a clump of Pampas Grass surrounded by four plants of *Ricinus* with its bronzy leaves, and five plants of the large Poppy, *Papaver orientalis*, which flower in June and then die down, when their place is taken by the *Ricinus*. Between each Artichoke (the Green Globe variety) are three plants of the tall-growing *Ageratum*, then a circle of variegated Iris and an edging of London Pride, with some plants of Geraniums of various colours at the back of the Iris; then there is a row of *Crocus* between the Iris and the London Pride. It will be seen from this arrangement that a continuous filling of the bed is provided for, and that as the earlier-blooming plants die down their places are supplied by others. Then there is another bed with a variegated Maple in the centre, and with a mixed collection of plants round it, which

are to be replaced shortly by a collection of the many beautiful varieties of Maple which have been of late years introduced from Japan. The belt at the end of the lawn has been excellently managed. It was necessary to shut out the road, so Laurels and quick-growing shrubs had to be planted. A wide belt was made for this purpose, but the Conifers of various kinds which were to be the prominent occupants of the belt were judiciously planted, and a broad edge of flowering plants placed in front; but as the Conifers grow the shrubbery is thinned out, the edging of plants is removed, and the turf is brought close up to the trees, which then sweep over the lawn. But I think the greatest triumph of all is the piece of water and its surroundings. There is a rivulet which comes down from the hills above, and which, skirting the farm, has been diverted here so as to form a very ornamental piece of water. It would not do to have it on a flat, and so a large quantity of earth has been brought here, banks are made all round and planted with hardy herbaceous plants and interspersed with some half-hardy plants from the greenhouse. On the water floated the white and yellow water Lilies, while on a wee island in the centre there was a clump of the double-flowering Arrow-head, *Sagittaria sagittifolia fl-pleuo*, which has sown itself on various places at the edge of the water. Amongst the plants used was the large-podded *Capsicum* with its brilliant red pods; this had an excellent effect dotted here and there over the banks. Now and then a bright bit of *Coleus* came in very effectively; and the effort had been made, not only to give a good general effect, but also to attract the eye with little bits of colouring which leave nothing to be desired in artistic arrangement. Then the trees, of which there are not many, are utilised, also creeping plants, *Aristolochias*, *Clematis*, &c., clothe their stems, while here is a standard *Jasmine* with a stem as thick as one's leg, and which must be very beautiful when its branches are clothed with their fragrant white flowers.

It might be supposed from all that I have said, and the quantity of plants that are used, that there must be a large number of houses wherein to shelter them, and I was surprised to find that only two, and they not very large ones, were required. Some of the hardier plants were sheltered in a shed, but the greater number were placed in these houses, which must be tolerably full when all are placed in it. Although no bedding-out in the strict sense of the term is practised here, yet bedding plants, *Pelargoniums*, *Coleuses*, *Calceolarias*, &c., are used to a good extent, and this involves propagation, which had been already completed; but I fancy that these will be less and less used, the desire of Major Horrocks being, as he expressed it, to get subtropical effects without subtropical plants.

I am writing about the garden, or else I should like to have said something about the orchard, which is one of the best examples of fruit culture I have seen for a long time, and where I saw more Pears than I have seen altogether this year in the places I have visited. And here, alas! I am at the length of my tether. I have only lightly touched on some of the many notable things in Mascalls, and I have said nothing about Weirleigh; and there as I mount the hill I see the burly form of farmer Weir shaking his fist at me, and telling me that luncheon is waiting; so I must part company with Major Horrocks and his very interesting garden, and reserve my notice of Weirleigh for a future issue. —D., *Deal*.

WELLINGTONIA GIGANTEA.

IN your issue of the *Journal of Horticulture* for September 23rd, Mr. Moss, on page 283, refers to the remarkable growth of *Wellingtonia* planted in 1863, the circumference of which at 6 inches from the ground is 9 feet 7 inches. Your correspondent also apprehends the wood of the *Wellingtonia* would be useful for building purposes. The growth referred to is certainly remarkable, and if the wood were hard and durable it would be a very profitable tree to plant extensively; but within the last two years I have cut down four or five of these trees, ranging from 25 to 40 feet in height, and found when having their trunks sawn into lengths that the wood was very soft, coarse-grained, and spongy-looking. It also soon decays. The relative girths and height of these trees, although of the same age, is also remarkable—for instance, a tree 53 feet in height is 9 feet 6 inches in circumference round the trunk at 6 inches from the ground, while another 30 feet in height at 6 inches from the ground also girths 9 feet 6 inches, and another tree 51 feet in height at the same distance from the ground is only 8 feet in circumference round the trunk. As an ornamental tree the merits of the *Wellingtonia* are well known, and if planted on soil that suits it its fine pyramidal habit will make quite a feature. It will not flourish on poor, stony, shallow soil, but will become a fine tree on a deep rich loam. As an evergreen avenue tree it has a noble appearance. A straight drive here half a mile in length,

with trees each side from 30 to 50 feet in height, has a grand effect; a curved carriage drive similarly planted does not look so well.—A. HARDING, *Orton Hall*.

MORE ABOUT POTATOES.

I AM not surprised at hearing that those who grow largely for the market hold *Champion* and *Magnum Bonum* in high estimation. The object they have in view—namely, to grow those crops which will afford them the best return with the least amount of risk, has naturally led them, after the experience of the past few seasons, to select these varieties as meeting their requirements best; and, provided that the bad seasons continue, and that the growers mean to give in, confessing that the disease has defeated them, and that they must have poor Potatoes or none at all, such a course would seem to be the wisest.

I am not prepared to give up the fight in this way, nor do I believe in continual bad seasons. I have taken the trouble to make inquiries among the principal growers in this neighbourhood, and find that although for several years their patience and their pockets have been sorely tried, they have this season been rewarded with an extraordinary crop. The disease has been practically nil, and the yield of all varieties enormous. Potatoes are ridiculously cheap. The common varieties have, I hear, been sold for as little as 2s. 6d. per sack of 160 lbs., which is less than a farthing per pound. The present price ranges from 6d. to 1s. per 20 lbs.

The varieties most in favour among market gardeners here are for a first crop *Myatt's Improved Ashleaf*, followed by *Gloucestershire Kidney*. Nothing has yet been found to supersede these old well-tried varieties. From personal experience I can speak well of them. *Myatt's* slightly sprouted in heat, and, planted in the open ground without any protection in January, was fit to dig on May 26th. *Early Rose* does not seem to meet with general approval. There appears to be a prejudice against this Potato, owing to the pink tinge which sometimes pervades it when cooked. In wet seasons, or when grown on heavy land, this defect often occurs. I grow it largely and consider it a most valuable early kind. This year the colour is excellent, and some tubers grown on light peaty soil are as white as snow and floury to the centre. The crop is quite double that of *Myatt's* and perfectly free from disease. Many people complain of not being able to grow this variety on account of its being so liable to disease. Even in the worst of seasons I hardly ever lose any from it, as by planting properly prepared sets sufficiently early, it is all dug and eaten or sold by the end of June. But, then, this is Devonshire, and I live on the top of a hill, and have hardly ever known the frost cut my Potatoes, although down in the valley half a mile away they are frequently blackened in May. *Snowflake* is another variety almost discarded by market growers. Like other white-flowered first-class Potatoes, it is undoubtedly very liable to suffer in wet seasons; but it is a splendid Potato, almost without a fault besides, and there is none that finds a more ready sale or commands a higher price in the market. I have kept to it; and though last season I only had half a crop, this year I have been rewarded with a magnificent yield of the finest quality with scarcely a diseased tuber among them.

Late Rose is another good variety very little grown about here. I find it to be a grand cropper, a good keeper, and second only to such as *Snowflake* and the old *Lapstone Kidney* for quality. The yield is at the rate of 12 to 14 tons per acre, quite free from disease. It finds a ready sale, and, being beautifully white and mealy, gives general satisfaction.

Among late Potatoes *Magnum Bonum* and *Champion* are the present favourites. The crop of the former is enormous and quite free from disease. The quality is barely second-rate, but the appearance of the tuber is good and helps to make it sell well, though not at the best price. In my opinion it is neither a garden Potato nor a Potato for a gentleman's table. A friend who has a large establishment and grows a great many Potatoes for home consumption asked me a day or two since to have a look at his field where four or five men were engaged in lifting. The principal crops were *Rocks* and *Magnum Bonum*. The crop of the latter was excellent, but he said, "I don't like them, they are waxy and the flavour is poor." My experience of it, as grown in rather heavy soil, is the same.

The open market is the finest test of quality that exists. Buyers are always willing to pay a good price for a good article. There I find that among kidneys the old *Lapstone* and *Snowflake* always head the list, commanding the highest prices; and though the superabundance of inferior varieties affects the price of the best considerably, there is still a good margin between them and such as *Magnum Bonum*.

Seotch Champion has been largely planted here as elsewhere. The crop is large and almost free from disease. From what I see and hear it is likely to prove a useful stopgap until another novelty turns up with fewer faults. The markets tell a tale as to its general appreciation for table. All the talk in the world will not get over the stubborn fact that Victorias and Regents are making from £5 to £6 per ton, while Champions are being given away for £3 10s. "AN IRISHMAN," "W. J. M.," and Mr. A. Barker think that the true Champion cannot be fit to eat in August. Some of mine were planted at the end of January and were quite destitute of foliage by the first week in August, owing to the hot dry weather, after being six months and a half in the ground. Others planted in April have just been lifted (September 20th). Surely this is long enough for even the latest Potato to arrive at maturity.

Individual opinions as their being white and mealy must be taken for what they are worth. There are relative degrees of

both. I have seen a flock of sheep appear beautifully white against the green grass; but the next day, after a fall of snow, they seemed to have changed to a dingy drab. Put a few good Victorias or Snowflakes into a dish of Champions, and the same effect will be produced. As to their being always good, whether boiled or baked, this may be so; I have never denied it. Except for their being rather too solid and rather coarse in flavour they may fairly be described as good; but there are three degrees of comparison—good, better, best, and Champion must be content with the positive. But my object in making these remarks is to record my opinion that growers should be careful about giving up old well-established varieties, and taking to these coarse novelties merely from fear of the disease. In the report of the Crystal Palace Show I observe that many varieties are mentioned of which I have no experience; but I like, and no doubt most others do, to try a few promising novelties every season if possible.

Fig. 62.—BELLE JULIE PEAR.

It would be a boon if any disinterested person who has grown them would give their experience. Vicar of Laleham, Woodstock Kidney, Radstock Beauty, and Pride of America are repeatedly mentioned. Who can tell us anything reliable about them? —R. W. BEACHEY.

BELLE JULIE PEAR.

OCTOBER and November Pears are so numerous and so good that no one would be warranted in adding another variety to the already rich list unless such variety possessed really good qualities. Belle Julie is a great and certain bearer; the fruit is distinct from all others by its warm hazel-brown colour, and its flavour is excellent. Last year a pyramid at Chiswick was perhaps more heavily laden with fruit than any tree in the garden, and this year the same tree has produced another excellent crop. Tested with such varieties as Marie Louise and Louise Bonne of

Jersey, the fruit of the variety in question was at the least equal to either, and some judges thought it superior. This variety is described as follows in the "Fruit Manual":—

"Fruit medium sized, long obovate, even and regular shaped. Skin rather rough to the feel from the large russety specks with which it is covered. The colour is dull brown, somewhat like that of the Brown Beurré; and on the side next the sun it has a warm reddish-brown glow, like a gipsy's blush. On the shaded side, where the skin is not covered with russet, the green ground colour shows through. Stalk an inch long, brown, and woody, inserted on one side of the fruit under a fleshy lip. Eye clove-like, wide open, with long segments, and set almost on a level with the surface of the fruit. Flesh yellowish, tender, buttery, melting, and very juicy. The juice is rich, sugary, and vinous, with a fine perfume. A most delicious Pear; ripe in the end of October. This ought to be more extensively cultivated."

As was stated last November Mr. Barron has also a high opinion

of this Pear, indeed on account of its uniform productiveness and good quality he esteems it one of the most serviceable Pears in cultivation. It is in commerce, but not yet possessed in quantity by all nurserymen. The figure represents a fair example of the fruit as grown at Chiswick, and the variety is submitted as likely to give satisfaction to those who grow it.

CULTURE OF THE PERSIAN CYCLAMEN.

It is generally recommended to sow Cyclamen seed in the beginning of spring with the view of having flowers the following winter; but with a warm pit, greenhouse, or vinery, in which the young seedlings will not be exposed to frost, there is no particular reason why it may not be sown any time. If you have saved some seed it can be sown now. Any pan, shallow box, or flower pot will do, employing a compost of loam, sharp sand, and good drainage. Those who have but limited time and space, and often have not patience to wait a year for nursery seedlings, would do well to purchase the flowering corms when they are beginning to grow, and they will have flowers from Christmas onward. My plants in a rather warm moist plant pit are now a mass of flower buds, and the leaves are pushing rapidly. A few days since in Dublin a lady showed me a frame full of Cyclamen in various stages of development. The older tubers were resting in their pots previous to being repotted, and the seedlings of last spring were preparing to flower. If a lady thus, with only a few yards of a town garden, a frame, and a southern parlour window, can have Cyclamens so good there surely cannot be any great difficulty in their culture.

I should remark for the information of those who have no other appliances than a frame, that if they could put in some stable manure to make a hotbed, which would last, say, three weeks, supposing it to be only 6 or 8 inches thick, in that time the seed would probably be started if the temperature rose to 70° or 75°, and when frost appeared, say six weeks hence in Ireland, the seedlings could be removed to a parlour or warm sitting-room, kept moist, and transplanted in spring. Last year a friend of mine raised as healthy seedlings in this way as ever I saw; from a packet of Suttons' Giganteum variety he had at least one hundred plants. In transplanting it is important that the little tuber be not sunk beneath the soil; if it is, the leaves will be likely to damp-off. I once found my tubers scooped out in little hollows here and there underneath by what I found to be a small maggot that is common in some soils. I think the easiest remedy is to throw boiling water over the soil some time before you use it, or if you do not fear the dissipation of the moisture or ammonia, place the soil into an oven, or in its absence into a close pan or pot. Overpotting should be strictly avoided; and if the soil gets hard into a firm compact mass, if you cannot readily soften and loose it shake out and repot the plants. I never wholly dry-off my plants, nor do I put them out to have their perennial rootlets dried up and desiccated. Ripen on a moist surface, with the plants and pots plunged, if in no other material, in common garden soil, and the beneficial treatment will be quickly apparent.—W. J. M., *Clonmel*.

INJURIES AND LOSSES SUSTAINED IN THE WINTER 1879-80.

—The Royal Horticultural Society, being desirous of obtaining trustworthy information as to the effects of the late exceptionally wet summer and severe winter on trees, shrubs, &c., would be glad to receive reports from gardeners, florists, and others. Schedules for recording such injuries as may have occurred will be forwarded to anyone who may be willing to assist the Society. About twenty-five returns have been received; but as it is desirable to render the report as complete as possible, it is hoped that every county in the British Isles may be represented by at least one return. One or at most two reports have been received from the following counties, &c.:—Arran, Bucks, Cornwall, Derbyshire, Dorset, Dumfriesshire, Essex, Gloucestershire, Herts, Roxburghshire, Kent, Kilkenney, Leicestershire, Middlesex, Midlothian, Somersetshire, Suffolk, Surrey, Sussex, Sutherlandshire, Warwickshire, Wicklow, Isle of Wight, and Yorks. Address to Rev. G. Henslow, 6, Titchfield Terrace, Regent's Park, N.W.

— AT a General Meeting of the ROYAL HORTICULTURAL SOCIETY held on Tuesday last, Col. R. Trevor Clarke in the chair, the following candidates were elected Fellows—viz., Dr. R. Abud, George M. Bell, Ebenezer R. Butler, M.D., Henry Cosier, Arthur Hibbert, Mrs. Cavendish Taylor.

— WE have received from Mr. Rivers of Sawbridgeworth a fine example of the GROS MAROC GRAPE. The berries are very large, nearly oval in shape, and in colour a bluish black of great intensity. In appearance this is an imposing Grape, and in quality is particularly sweet and refreshing—not of a nature to cloy the palate. The Vine is a good grower and bearer, succeeds well in a house with Black Hamburgs, and the fruit keeps for a considerable time after it is ripe. Since the above was written the Fruit Committee of the Royal Horticultural Society have awarded a first-class certificate for this Grape.

— "ORCHID GROWER" writes—"A very fine variety of VANDA TRICOLOR is now flowering in the Orchid house at Kew. The markings of the sepals and petals are very distinct, whilst the lip is a bright rosy lilac. The plant is bearing two fine spikes of flowers, which emit a delicious perfume. Dendrobium formosum giganteum is flowering freely in the cool house. Two good spikes of flowers proceed from the apex of the pseudo-bulbs. The flowers are pure white, with a blotch of lemon yellow at the base of the lip. It is growing on a block suspended from the roof, and evidently enjoys the treatment it receives by throwing out its long white roots in search of moisture. Near the above-mentioned plant is Epidendrum purum in flower. The flowers are creamy white, and densely packed in a drooping inflorescence a foot or so long."

— MR. IGGULDEN writes as follows on LOPHOSPERMUM SCANDENS:—"It forms one of the most attractive climbers imaginable for a temperate house, and is now in splendid condition in Capt. Jackson's garden at Meopham. The plants are growing in a low span-roofed house, are potted into 8-inch pots, and from these the roots are allowed to extend into an old, levelled, and well-trodden Melon bed. They are trained directly over the pathway along three of the topmost wires, and present a most brilliant appearance, the branching growth being clothed with innumerable crimson trumpet-shaped flowers. Plants are easily raised from seed, are useful for cutting from, and can be used very effectively in vases."

— IN the same garden Mr. Phillips grows TUBEROUS-ROOTED BEGONIAS remarkably well. Some of his seedlings are particularly fine, although scarcely distinct from many in commerce. So well are a number of seedlings growing and flowering that are pricked out in the above-mentioned Melon bed, that the question arises, Why not plant them out in the conservatory beds? They would undoubtedly well repay the little trouble necessary, and might easily be lifted and stored away during their resting period. Planting appears to intensify their generally bright colours, and strong loamy soil especially seems to suit them.

— "A BEAUTIFUL plant" writes "W. R.," "for the stove is ÆSCHYNANTHUS GRANDIFLORUS. I have a specimen now bearing two large umbels of bright orange-scarlet flowers, with a band of brighter scarlet round the entrance of the tube. The flowers are about 3 inches long and of great substance. This is really a grand species, and should be in every collection of plants however small."

— WE have received some pods of CARTERS' CHAMPION SCARLET RUNNER BEAN grown by a Leicestershire cultivator. They are very large, fleshy, and crisp, and are excellent examples of this well-known good variety.

— WE are glad to learn that the SHREWSBURY SUMMER SHOW, that was fully reported in our columns, was a great success,

and resulted in a profit to the Society of £500. Notwithstanding the loss arising from the Rose and Autumn Shows, the Committee are able to add £350 to the reserve fund, making the total of that fund £1200.

— THE Metropolitan Board of Works have arranged for holding a CHRYSANTHEMUM SHOW IN FINSBURY PARK. The display will be arranged in a temporary glass structure by Mr. Cochrane the Superintendent, and will be open to the public on the 23rd inst. The plants are in very good condition.

— MR. CROSSLING'S seedling TOMATO GLAMORGAN, which has been referred to approvingly in these columns, will, we learn, be distributed by Messrs. Osborn & Sons of Fulham.

— ON Saturday and Monday last an EXHIBITION OF GLADIOLUS AND DAHLIAS was held at the Royal Aquarium, Westminster. The blooms were tastefully arranged in vases and ornamental glasses on a table about 150 feet in length, and the combination of bright colours produced a pleasing effect. Messrs. Carter and Co., Holborn, exhibited collections of Potatoes; and Messrs. Lane and Son, Great Berkhamstead, contributed samples of Grapes.

— MESSRS. CHRISTY & CO., Fenchurch Street, have received a consignment of the Chinese reputed remedy for skin disease, known as Tong-pang-chong, and believed to be the product of RHINACANTHUS COMMUNIS. Specimens of this drug were sent to Kew about three years ago from Hong Kong, and were subsequently described by Sir Joseph Hooker as resembling portions of a woody root. In comparison with specimens of Rhinacanthus in the museum a great similarity was observed, but no doubt the true source will now be definitely settled.

— IN Mr. B. S. Williams's nursery at Upper Holloway several beautiful and useful Orchids are now flowering, and perhaps they are especially noticeable owing to the comparative scarcity of Orchid blooms during October and November. THREE GOOD ONCIDIUMS for attractiveness and their late-flowering habit are *O. aurosum*, *O. Forbesii*, and *O. ornithorhynchum*. The first has a rather short dense panicle of yellowish medium-sized flowers; *O. Forbesii* bears a panicle of handsome large flowers marked with yellow and a rich brown or chocolate colour; while the charming *O. ornithorhynchum* has compact branching panicles of small rosy purple blooms. A specimen of the latter is suspended from the roof of one of the Orchid houses, and the seven or eight pendent inflorescences render it extremely attractive.

— A BEAUTIFUL and comparatively rare Orchid—namely, *LÆLIA WOLSTENHOLMÆ*—is flowering in the same nursery. The petals and sepals are narrow, tinged with purple, and edged with a slightly darker shade of the same colour, the labellum having a centre of extremely rich purplish lake. It is one of the best forms of *L. elegans*, and was named in honour of Mr. Day's sister, Mrs. Wolstenholm.

— NEAR the above is a specimen of *PERISTERIA ELATA*, the Dove or Holy Ghost Plant, the *El Spirito Santo* of Panama. This charming Orchid is comparatively well known in most large collections, but it deserves the attention of those who can only afford space for a few. It produces a spike of roundish deliciously fragrant creamy white flowers, with fleshy sepals and petals, the labellum being spotted with pale lilac or blue.

— MR. G. LEE of Clevedon communicates the following relative to his SEEDLING ASTER that we referred to last week:—"There are ten stems on the plant, but which are as upright as their branches will allow. The extreme height of the stem is 3½ feet. The height of stem to lower branches 2 feet. The length of lower branches is 1 foot 3 inches. The number of branches on one stem twenty-five. The advantages of this seedling over other varieties are its lengthened period of flowering and its profusion of bloom,

the size of the flowers, and their bright colour. It commences flowering towards the end of August, and continues till the end of this month—quite nine weeks." Mr. Lee states this variety is a seedling from *A. novi-belgii*, but it appears to be intermediate between the two good varieties of *A. novæ-angliæ*—*pulchellus* and *roseus*, and is one of the most beautiful varieties we have seen.

— WE are requested to state that Mr. H. G. SMYTH has removed his establishment for garden requisites from Nos. 10 and 12, Castle Street, Endell Street, Long Acre, to more extensive and convenient premises, at 17a, Coal Yard, Drury Lane, London, W.C.

— WE are informed that Messrs. Stevens & Pinches' ACME TREE AND PLANT LABELS, figured by us in January last, can now be had with the names of 850 Roses and 550 fruits struck with a die, and raised above the opaque surface, consequently they are ineradicable and durable.

LIFTING UNRIPE POTATOES.

PERHAPS I may sound a note of warning to the inexperienced against lifting their Potatoes too soon. A year or two ago I read an article by, I think, Mr. Luckhurst, advising the lifting of all Potatoes when still in a growing state and before the disease had taken hold of them. I had six varieties planted, and I had every Potato uprooted forthwith, and very clean and pretty they looked. I took the greatest possible care with their tender skins and stored them thinly in a dry room, locked them up and felt happy. In a week or two after my neighbours began to complain of the dreadful disease. I smiled very blandly, and told them they ought to have them up and out of harm's way, and invited some of them to come and see my Potato room. I proudly flung open the door. But why linger over a tale of horror? I commenced to buy Potatoes a few weeks after.

This year I have saved upwards of one hundred measures of Myatt's Kidney, and have stored the tubers at seven distinct and separate times, noting down carefully the circumstances and conditions under which each lot were stored. The result is, that in the lots lifted last, and consequently when the tubers had attained their full growth, there is scarcely one diseased, whilst in those first lifted very many have become mere hard dry decayed husks. This has proved to my mind more than any amount of theory that it is a mistake to lift the tubers until they are quite ripe. It is too late for my experience to be of benefit to others this year, but could we not arrive at some conclusion before the season of 1881? I have this year grown (the second year from the berry) a distinct new variety much darker and better shaped than the Skerry Blue, which I hope to prove next year.—A. K. B.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 12TH.

THE meeting of the Society's Committees on Tuesday last was exceptionally well attended, and the exhibits in fruit, vegetables, and plants were sufficiently numerous to produce a good display. Fine collections of Apples from Messrs. Veitch and Lane occupied considerable space in the Council-room, Messrs. Veitch, Cannell, Williams, and the General Horticultural Company contributing a number of Orchids, fine-foliage and flowering plants. The Dahlia blooms from the Society's gardens formed the chief feature among the exhibits of flowers, and well indicated the beauty the Pompon race of Dahlias possess.

FRUIT COMMITTEE.—John Lee, Esq., in the chair. Messrs. Osborn exhibited a dish of their new Fig, called Osborn's Prolific. It had been grown on the back of a cool house, and was excellent in flavour; but the Committee, considering it was shown so late in the season, and having been produced under unfavourable circumstances, expressed a wish to see it again. Messrs. Rivers & Son of Sawbridgeworth sent a dish of their new late Plum Grand Duke. It is a large dark Plum, in appearance like Diamond, but much superior in flavour, and very valuable for its lateness. It was awarded a first-class certificate. Another seedling, No. 15, was similar in appearance, but not so good as the former. No. 8 is another large dark oval Plum, similar in appearance to the two former; but it was not equal in flavour to Grand Duke, though superior to No. 15. Messrs. Rivers also exhibited a bunch of Gros Maroc Grape, very handsome, and well set with large berries, and finely coloured. This was highly appreciated and much admired by the Committee, and was awarded a first-class certificate. Mr. R. Gilbert, The Gardens, Burghley, exhibited a bunch of each Black Alicante and Abercainey Seedling Grapes. The former was quite unripe; the Abercainey was in fine condition, but on inquiry they were found to have been grown in different houses. It was arranged for it to be exhibited again at the meeting in December,

when it will be compared with other varieties with which it is most like. Mr. Woodbridge, The Gardens, Syon, Middlesex, exhibited fruit of a Banana called *Musa Rajah*, which was introduced by Mr. Burbidge from Borneo, where it is grown for use at the tables of the wealthy. The flavour was inferior.

Mr. R. Gilbert exhibited specimens of his Cabbage Broccoli, which was certificated last year. Some of it was cooked, and highly approved by the Committee. Mr. Muir, The Gardens, Taibach, also exhibited specimens, which were identical with Mr. Gilbert's. Mr. Iggulden, The Gardens, Orsett Hall, Romford, exhibited specimens of his strain of Cabbage Broccoli. It differs from the former in being more loose in the head, and consequently not so much blanched. This was also cooked, and considered by the Committee more delicate in flavour than the former, which were both strongly flavoured.

Mr. Wildsmith, gardener to Lord Eversley at Heckfield exhibited six specimens of Pitmaston Duchess Pear, remarkably handsome. They weighed in the aggregate $7\frac{1}{2}$ lbs. A cultural commendation was unanimously awarded. Mr. Barron exhibited the following Pears from the gardens of the Society at Chiswick:—*Souvenir de la Reine*, a medium-sized yellow Pear, with crisp flesh and a good flavour; *Souvenir du Congrès*, a large and handsome Pear, but inferior in flavour; *Vineuse*, a large Pear and with a rich flavour and a high perfume, a very deliciously flavoured Pear. It was awarded a first-class certificate. *Poire de Berrays*, inferior in flavour. Mr. George Swinerd of Minster, Kent, sent a dish of the Thanet Quarrenden Apple, raised from seed of the Devonshire Quarrenden in 1859. The fruit is larger than the old Quarrenden, and exactly like it, but not so highly coloured, nor is it stained in the flesh as the old Quarrenden is. The flavour is sweet but the flesh is woolly. Mr. R. Gilbert exhibited a seedling Apple called *Barnock Pride*, a good-sized and highly coloured Apple with a very tender briskly flavoured flesh. Mr. C. Noble, Sunningdale, sent a small seedling Apple, but it had not much flavour. Mr. Dean of Ealing sent branches of *Swan's Egg* and *Seigneur Espere* Pears laden with fruit. Mr. Carmichael, The Gardens, Nowton Court, Bury St. Edmunds, exhibited a handsome fruit of his *Victory of Bristol* Melon, and a seedling *Stirling Castle*, which was over-ripe. A third variety, called *Victorious Hero*, a red-fleshed sort, was well flavoured, but it was too late in the season for it. Mr. Mann, The Gardens, St. Vincent's, Grantham, sent a seedling Melon, the flavour of which was inferior. Mr. Charles Ross, Welford Park Gardens, Newbury, sent a seedling Melon raised between Sutton's Horticultural Prize and Eastnor Castle. It was of good flavour but not remarkable. He also sent one "No. 2," raised between Colston Bassett and Read's Searlet. It is a fine, rich yellow, smooth-skinned ribbed Melon, with a pink flesh, and very richly flavoured. It was awarded a first-class certificate, and received the name *Welford Park*. Messrs. Rivers sent a specimen of *Prescott Rock* Cantaloup, grown under a handglass, but it was inferior in flavour.

Mr. Hinds, gardener to Lord Wimborne, Canford Manor, sent a dish of *Hind's Improved Trophy* Tomato, a fine plump even-surfaced Trophy, similar to *Stamfordian*, but more ribbed and not so good. Mr. Clark, gardener to Lord Hastings, Melton Constable, sent specimens of *Carter's Golden Drop* Turnip, and specimens of this and *Jersey Lily* also came from the Society's gardens at Chiswick.

Mr. D. Wilson, gardener to Earl Fortescue, sent five Smooth Cayenne Pines and three *Charlotte Rothschild*. The heaviest of the Cayennes weighed 8 lbs. 2 ozs. and $7\frac{1}{2}$ lbs.; *Charlotte Rothschild* weighed $6\frac{1}{4}$ lbs. They were awarded a silver Banksian medal. Mr. Goodacre, The Gardens, Elvaston Castle, sent two bunches of each of twelve varieties of Grapes. A letter of thanks was awarded. Messrs. Lane of Berkhamstead exhibited seventy varieties of Apples, and Messrs. Veitch & Sons exhibited ninety varieties of Apples. Each was awarded a letter of thanks.

Messrs. Freeman & Freeman of Norwich offered two prizes for collections of vegetables to be the produce of seed supplied by that firm. Only one collection was staged, but that was an exceptionally good one; the exhibitor, Mr. J. Clarke, gardener to Lord Hastings, Melton Constable, East Dereham, Norwich, easily securing the handsome first prize of £25. The collection included over forty varieties, well grown and in admirable condition generally. Some of the most noticeable were the following, all sent out by Messrs. Freeman:—*Improved Dark Red Beet*, very even and fine; *Earliest Ashleaf* Potato, even and of moderate size; large *Summer Cabbage*, very fine; *Yard Long* Cucumber, *Prolific Vegetable Marrow*, *Defiance Celery*, and *Champion Cauliflower* very large. Some good examples of *Trophy* and *Greengage* Tomatoes were also shown, with Carrots, Onions, Savoy, Leeks, Peas, and many others very fresh and clean.

FLORAL COMMITTEE.—Dr. Denny in the chair. Although the plants submitted to the attention of the Committee were not unusually abundant, yet there was a brightness and interest in what was staged that was very satisfactory. Messrs. Veitch & Sons, Chelsea, exhibited a number of Orchids and other plants, three pans of the lovely *Pleione lagenaria* being especially noteworthy; one pan about 2 feet in diameter was a mass of flowers, upwards of a hundred being fully expanded. A cultural commendation was awarded. Specimens of *Stevia glandulosa*, a New Granadan plant bearing numerous heads of white *Eupatorium*-like flowers were shown; the plant is fairly compact in habit with acute bright green leaves, and it flowers very freely. *Lilium longiflorum verum* from the open ground was also shown, having one fine flower. *Odontoglossum Andersonianum* with two

fine racemes of flowers, *Oncidium varicosum*, *Pachystoma Thompsoni*, and several *Cypripediums*, with other Orchids described below, were interesting and pretty.

Mr. H. Cannell, Swanley, Kent, exhibited a box of *Pelargonium* blooms comprising twenty excellent varieties; *Lizzie Brooks*, W. B. Miller, Guinea, and Mrs. Strutt being particularly fine. The arrangement of these flowers deserves notice, the *Pelargonium* blooms being placed in rows alternately with Violets on a bed of *Stoncrop*. Some fine *Tuberous Begonia* blooms were staged, also leaves of *Chilian Beet*, the leafstalks, and midribs varying in colour from pure white to yellow, pink, red, and crimson. Flowers of *Abutilons* grown out of doors were also exhibited in fine condition. A vote of thanks was awarded for the collections.

Mr. B. S. Williams, Upper Holloway, contributed several new plants. *Nephrodium plumosum* is a graceful species, with fronds about 2 feet in length, pinnate and arching. *Cypripedium Haynaldianum* has flowers of medium size, the labellum small and greenish, the petals and sepals similar, but tipped with purple and spotted. *Gymnogramma Alstonii* has neat bipinnate fronds 6 to 8 inches in length, and bright golden colour beneath. *Croton Stewartii* was represented by a fine specimen 4 feet in diameter and nearly the same in height, the obovate or oblanceolate leaves being dark green and richly veined and marked with bright yellow. A botanical commendation was awarded for *Saccolabium denticulatum*, a diminutive plant with a tiny raceme of yellowish flowers. A specimen of Williams' *Superb Cockscombs* was shown with enormous finely formed and richly coloured head. The strain was commended. *Nepenthes Hibberdii*, a form with small neat pitchers streaked with red, was also noticeable.

The General Horticultural Company sent several new plants, among which were *Draena Countess of Lathom*, neat in habit, the leaves 2 or 3 inches in diameter, green, broadly striped with red; *Aralia Chabrierii*, a species with linear leaves 8 to 10 inches in length, very dark glossy green with a fine red midrib—the habit of the plant was rather graceful; also a *Cyperus*, which is described below.

From the Society's garden, Chiswick, large collections of bouquet and single-flowered Dahlias were exhibited, which from the brightness and diversity of their colours attracted great attention. The majority of the varieties were of Continental origin, but the English-raised forms were also well represented. Some of the best varieties were the following—*Guiding Star*, white, and neat in form; *German Favourite*, crimson shaded, neat; *Olga Kreutzburg*, bright yellow, good form; *Ich bin so Schön* (I am so pretty), very diminutive, rosy crimson; *Schönste der Schönen* (Fairest of the Fair), very bright red; *Bild der Anmuth* (Picture of Grace), pale lilac, extremely symmetrical; *Pure Love*, pale lilac, globular in form; *Frau Schneider*, peculiar chrome yellow, florets quilled; *J. C. A. Stanze*, yellow with a rosy tinge, very neat; *Rother Riesi* (Red Giant), very small, rosy purple, good form; and A. F. Barron, an exceptionally handsome flower of a pale sulphur tint, the florets having the margins infolded.

Messrs. James Carter & Co., 237 and 238, High Holborn, sent five seedling Coleuses—namely, *Fair Maid of Kent*, *Rosy Morn*, *Burning Bush*, *Commander-in-Chief*, and *Excelsior*, the two latter being distinct and pretty. Mr. H. Eckford, gardener to D. Sankey, Esq., Sandywell Park, Cheltenham, also sent several handsome seedling Coleuses, *Montargis*, *Venti Miglia*, and *Dijon* being especially fine and distinct.

First-class certificates were awarded for the following plants:—*Cyperus laxus variegatus* (The General Horticultural Company).—This is a very attractive plant, and will prove useful for decorative purposes. It is about a foot to 15 inches in height. The leaves and bracts are 4 to 6 inches in length, about half an inch broad, very prettily striped with white and green.

Angræcum Kotschyi (Veitch).—An epiphytal species from Zanzibar, with short and broad leaves and a long raceme of flowers, which are creamy white in colour, with pendent twisted spurs 6 or 8 inches in length.

Cattleya Marstersoniae (Veitch).—This is stated to be a hybrid between *C. Loddigesii* and *C. labiata*, and for neatness of form it is one of the best in cultivation. The sepals are narrow, of a delicate pale purple tint; the petals similar in colour, but rounded. The labellum is white in the throat, with a tip of bright rich purple.

Lilium longiflorum verum (Veitch).—This is a Japanese form, with narrow dark green leaves and long pure white wax-like flowers, the sides of the petals being scooped out so as to give a peculiar and very distinct appearance to the flower.

Dahlia William Rawlings (Rawlings Brothers).—A show variety of great beauty. The bloom is deep and symmetrical in outline, but the centre is rather flat. The colour is a deep rich glowing tint of crimson purple.

AT the usual meeting in the afternoon for the election of Fellows the Rev. G. Henslow delivered a short but interesting lecture upon the plants exhibited. He first alluded to the beauty of *Pleione lagenaria* and the peculiarity of the genus, consisting in its dwarf habit and in flowering before the production of leaves. The peculiar *Angræcum Kotschyi* was also referred to, the lecturer stating that he did not know another species of Orchid that had a similarly twisted spnr. He suggested that it was probably of some service to the plant, being possibly similarly sensitive to some tendrils, and aiding in the support of the rather heavy inflorescence. This led to a description of *Angræcum sesquipedale*, which is well known in connection with Mr. Darwin's

remarkable observations concerning the necessity of there being some insect with a sufficiently long proboscis to reach down to the bottom of the spur where the nectar is secreted, which was afterwards found to be perfectly correct, though the insect was unknown at the time the observation was made. The colouring in the leafstalks of the Chilian Beet and the foliage of Coleuses was also briefly noted, Mr. Henslow stating that he hoped to make some progress in investigating the subject by aid of the spectroscope. Concerning the Coleuses he remarked that recently when in Switzerland he had noted that they were very commonly bedded-out, but although the varieties were numerous they were very dull in colours and devoid of beauty that characterise so many English-raised forms. The collections of Dahlias from Chiswick gave occasion to some remarks concerning the

history and development of the genus. The first introduction of the Dahlia, or Georgina, as it is often called on the Continent, was by the Marchioness of Bute, who received it from Madrid in 1789. The plants perished, and a second introduction was made by Lady Holland in 1804. These also perished, and it was not till 1814 when it once more became established, this time from France, where it had been cultivated in the hope of its tubers proving edible. They were too acrid either "for man or beast." The principal species under cultivation is *D. variabilis* or *superflua*. This has given rise to innumerable forms large and small. *D. coccinea* is perhaps best known in the single state, and does not appear to have contributed much to floral display. *D. glabrata*, *D. coccinea* were both represented from Chiswick, as well as *D. Cervantesi*, which did not appear cursorily

Fig. 63.—HIBISCUS SYRIACUS.

to differ much from *coccinea*. The lecturer then explained the nature of "doubling" in Compositæ, and pointed out two forms on the table—one, the ordinary kind, where the folded corollas were flat, another in which they approximated the "quill" type by being nearly cylindrical tubes. A third variety had each petal deeply cleft twice, revealing the origin of the corolla, in that it is composed, as in all "ligulate" florets (excepting the tribe *Cichoriaceæ*) of three petals, in consequence of the suppression of two in the change from a tubular to a ligulate corolla.

At the conclusion of the lecture a vote of thanks was accorded to Mr. Henslow. Col. Trevor Clarke drew attention to a healthy plant of *Oncidium ornithorhynchum* growing in moss in a small pot. He stated that he had employed moss placed in the pots very firmly for

several other Orchids, and they succeeded equally as well as in peat. It was announced in conclusion that the next meeting of the Society will be held on November 16th.

HIBISCUS SYRIACUS.

IN the search for something new and novel the merits of the old and good are sometimes overlooked. As may be seen by the engraving of some sprays which are represented precisely as they were gathered a month ago, this is one of the most beautiful autumn-flowering shrubs in cultivation. In some districts it is largely grown, and imparts a most cheerful aspect to shrubberies

and pleasure grounds; but in others miles may be traversed and a hundred gardens visited without seeing any specimens of the Syrian Hibiscus, or, as it is commonly known, *Althæa frutex*.

Hibiscus syriacus has long been known, as it was introduced nearly three centuries ago. It was described by Gerarde, also by Parkinson, but at that time was not considered hardy, as this old and very precise writer observes—"These woody kinds of Shrub Mallows have somewhat large, long, and divided leaves set dispersedly on the whitish hard or woody stalks; their flowers are large like unto a single Rose or Hollyhoke, in the one being white with purple spots in the bottom; in the other of a deeper red colour, or else of a paler purple with a deeper bottom, and with veins running in every leaf; they are somewhat tender, and would not be suffered to be uncovered in the winter time, but kept in a large pot or tubbe in the house, or in a warme cellar, if you would have them thrive."

The old author's description is very accurate; but whatever the shrubs needed two hundred years ago they do not need a "tubbe" and warm cellar to have them thrive now. They are perfectly hardy, but to have them in the best condition they should have positions fully open to the sun, so that the growth becomes mature and a floriferous habit is induced. Specimens 10 feet high and through, bearing hundreds of flowers, are surpassed by few flowering shrubs, and equalled by none that are established in our gardens and flower in August and September. There are several varieties, some with variegated foliage and others with double flowers, but the two ordinary forms figured, the purple and white, are as free and effective as any; and, as the planting season is approaching, these old and good flowering shrubs should not be forgotten.

FUNGI ON POTATOES.

I THOUGHT it was an undisputed fact that the fungus was the cause of the Potato disease, and not a result. I have always found the spots spread from a minute centre either on the leaf-stalk, tuber, or fibre. Again, I have often found that plants in the most confined sheltered spots are attacked first either in the field or garden. I have often noticed this, and if the weather continues dry the fungus does not spread beyond its original first patch; and again, if those first affected are carefully removed at an early stage of its appearance you save the surrounding crop; otherwise if the weather is favourable it spreads from these centres most rapidly, whereas if the weather continues very dry or the first attacked patch is carefully removed, I have found it has not spread for weeks. I ought perhaps to say that almost invariably the under part of the leaf is affected first. I say, Almost invariably, for sometimes the very centres of the young growths are affected, on the edges of the leaves on the upper sides, under sides, or wherever the spores, according to my view of it, first fix themselves. My reason for this is that such parts are the most tender in tissue, and therefore the most favourable to the growth of the fungus. My impression is that the spores are carried upward from the earth by evaporation, and after a shower the under part of the leaf will be found quite wet long after the upper part has been dry, so that they more readily fix themselves to the wet tender parts. Again, as to the stem, it will be found, I think, that the most fleshy parts if screened by leaves are those affected first. Examine the fibres: if a fungus is not the cause why is the extremity, as also that attached to the stem, perfectly sound, and the other part, just a spot of a few lines or an inch or two, quite perished. As to the tubers, I think all are agreed that the largest are the most likely to be affected. Now, why is this? I think it is because there is more space for the spores to grow than on the smaller tubers; and again, why are some tubers affected in six or eight or more places, some only in one? Another argument, "if I may be allowed the expression, to prove that fungus is the cause and not the result, will be found in a variety of Potato being planted in different soils, say one well drained and dry, thoroughly exposed to the air, and not rich, and the other in a well-drained but moister soil, such as Cabbages or Broccoli would delight in. In the summer in the one you get a sturdy growth, especially if about equal space is given to each set in both situations. In the rich soil the Potatoes grow luxuriantly with disease early and far-spreading both in top and tuber, whereas in the poor soil the plants possibly escape disease altogether. Now why is this, except that the tissues are more tender and therefore more readily attacked by the spores which more readily germinate on the tender tissues?

With regard to the tubers after they are lifted, I well remember about twenty-five years ago I lifted some old Ashleaf Kidney that I intended for seed. Part of them were removed at once to a loft and spread not more than three deep, the others were left on the

ground two or three weeks. The latter were mostly diseased, quite 80 per cent., while those in the loft had only about a dozen diseased Potatoes out of several sacks. How is this to be accounted for if the development of spores is not the cause of disease?

There is one more fact I wish to state—namely, give your Potatoes sufficient room between the rows for all haulm to be laid between them, and secured so that no part shall rest on the rows where the tubers are underneath, and the result will be, that although you cannot save the tops from the attacks of disease, you do save the most of your crop large and small. I cannot account for this except that the majority of the spores that fall from the tops get fixed to the soil underneath where they fall, and the most of those that rise into the air are borne away, and do not settle on the plants. I think it might as reasonably be argued that dry rot in timber is not the result of the attack of a fungus. It does not matter much how healthy and vigorous a tree is, bring dry rot into contact with its wood, and you will find that it will soon and effectually do its work. I could give many more illustrations.—GEORGE LEE, *Clevedon*.

THE EFFECTS OF ELECTRICITY ON VEGETATION.

SPEAKING of atmospheric electricity, and having described electricity as an attracting and repelling force, it will be very difficult for the non-scientific reader to at all realise the conception of an existing attraction surrounding him which he can neither see nor feel; yet such is the fact, and hence it will be desirable to suggest a very simple experiment by which it may be made evident. For this purpose, however, we may have recourse in the first instance to magnetism, the attractions of which are precisely the same. Procure a small horseshoe magnet and place it upon the table without its iron keeper; or, what is preferable, set a thick book up endwise, and lay it across the top so that the two ends may project beyond it. Now hold a small key or the soft iron keeper, which has no magnetism itself, a short distance in front of the pair of ends, but without touching them, and it will at once become a temporary magnet. Hold a fine sewing needle to the keeper and it will cling to it, and after the two have been removed it is probable that the hardened-steel needle will have been converted into a permanent magnet, whilst the soft iron will have parted with its magnetism altogether. An electrical atmosphere surrounds the magnet which can neither be seen nor felt, and can only be made apparent by its effects. Some iron filings sifted on to a piece of thin paper stretched tightly on a frame and placed over the magnet, and the frame then tapped, they will arrange themselves in beautiful magnetic curves and lines, which must be seen to be comprehended.

Corresponding to this the earth has also an electric aura enveloping it in the same manner, and consequently all objects within it will be affected in some one way or other. But to make this attracting atmospheric force recognisable a somewhat different arrangement will have to be adopted, for instead of magnetism we shall now have chemical action as the result.

Procure an ounce phial and a piece of copper wire just long enough to be enclosed within it, as in fig. 64; put in dilute sulphuric acid (one to ten) to one-half the depth or less, and cork it up with the wire as represented; very soon the upper part of the copper will begin to appear damp, and after a time the whole upper part will have become quite wet. Then minute granules will be seen studding nearly the whole of the exposed portion of the metal, and these ultimately will develop themselves as the very beautiful intense blue crystals of sulphate of copper. Now, if we put a second portion of the same wire and acid into another phial, so that the whole of the metal may be submerged and out of contact with the air, as in fig. 65, it will be seen that little or no solution of the metal will have been effected, as evidenced by the absence of colour in the acid; and therefore it is a proof that the dissolving of the metal is owing to the partial contact of the latter with the atmosphere contained in the phial. Here, then, is the very remarkable fact of substances being attracted (or repelled) upwards in direct contrariety to the ordinary law of gravitation. But there is another feature far more significant and important in its bearing on our present subject. By referring to fig. 66, which is the wire of fig. 64 enlarged, it will be seen that the copper has been eaten partly through just beneath the lower edge of the crystalline deposit. This, however, is the portion that was located just above the surface of the acid (A, fig. 64) and hence it was exposed to the lower surface of the atmosphere, where the acid and the air meet. It will be within the knowledge of most persons that wooden posts and railings are rotted off just above the surface of the ground in the same manner, so that our experiment represents precisely the same result that occurs in nature. It has always

been attributed to "the damp;" but this alone will never suffice, for it is well known that wooden posts and timbers and ancient canoes have lain for centuries buried within the earth, and when subsequently exhumed have been as solid as they were at first. As suggested by Faraday, "we must infer the unknown from the known." Trees and plants being situated in precisely the same manner—part in the damp earth and part exposed to the atmosphere—it is therefore a legitimate inference that a similar result must follow. Every gardener knows full well that the collar or neck of a plant which forms at this meeting of the air and the earth is the vital part of the plant, and where it is most easily killed, and which is thus explained; it is here that the food is converted into sap, which sap then flows upwards and becomes distributed all over the plant.

In the grammar of physical science there are various laws and rules that are never infringed, but are invariably followed to the letter; thus, in electro-chemical action fluids are always passed to the negative. In the decomposition of water oxygen invariably makes its appearance at the positive, whilst hydrogen is evolved at the negative. Alkaline salts, metallic deposits, and crystallisations of every description form at the negative; but acids, being

Fig. 64.

Fig. 65.

Fig. 66.

negative, accumulate at the positive electrode. The distinction between electro-chemical and ordinary chemical action is that in the former the resulting compound is attracted and drawn away from the point where it was formed to some other locality, as in the sulphate of copper being repelled upwards; but in ordinary chemical action, as in the mixture of an acid with an alkali, the combined elements remain where they are placed, there being no attracting or repelling power to enable them to shift their position, moisture in all cases being indispensable.

Respecting the nature of electricity this, from whatever source it may be derived, is always the same. It has this peculiarity, that in its active state it consists of two opposite forces, like one force polarised or divided into two; the attracting power being confined between themselves, each one repelling its like. Scrape some sealing wax on to a piece of paper, and then rub the same piece of wax on the coat sleeve, and although it will then attract small feathers or scraps of paper, it will have no attraction for its own scrapings, because they are of the same electric condition as itself.

By the law of induction, like magnetism inducing magnetism, it is impossible to have one condition of electricity without the other being present in like proportion of quantity and intensity. This is a very important point to be remembered, as it constitutes a leading principle in most of the phenomena of life and culture. Thus, if we excite increased action at the roots, an equally increased action in the plant must follow of necessity provided the plant be in a condition capable of responding, otherwise, like the excess of oxygen upon the seeds and from rusting iron, the balance will be destroyed and death speedily follow. Then, again, whenever an electrical condition is thus induced, it is always of the opposite character to that by which it was so induced. From this law of induction, and the earth being negative, the atmosphere becomes normally positive. These two relative conditions are essential to vegetation, or, if both be positive or both negative as was the atmosphere and earth in the plant-case previously alluded to, ordinary plants cannot possibly flourish; but a different character of growth altogether makes its appearance. As this, however, belongs more especially to the production of mildew and the cultivation of Mushrooms, &c., it must therefore be left for the present.

In order to enable us to comprehend the way in which oxygen is made subservient at the collar of the plant, it will be needful to explain the precise manner of its operations in connection with the copper wire. The lower portion of the latter, by its immersion in the negative acid, is at once rendered positive, whilst the upper portion by the positive atmosphere surrounding it is at the same time rendered negative. The next step is that this upper negative portion becomes damp on its surface as previously stated. The wire, being positive under the part so wetted, attracts and combines with the oxygen from the atmosphere, when the thin film of acid immediately dissolves and becomes saturated with it, and in its journey upward deposits it in crystallisation. It will be observed that the copper wire, after it has been a long time in the acid, has been less and less acted upon in proportion as it becomes more deeply immersed, and consequently further from the air-surface. This fact affords a good illustration of the advantage of roots being near the surface so as to be well within atmospheric influence.

In the rotting gatepost we have a corresponding action, but with somewhat varied results. The union of the oxygen with the carbon of the wood produces a soluble compound—carbonic acid; but which, not being crystallisable by ordinary means, and there being no organisation going on in the wood to effect its utilisation, it disappears into the atmosphere, and the post becomes lessened in its bulk imperceptibly, and without the usual discoloration of ordinary decay. In the latter it is the carbon that is left; but in this case it is the carbon itself that is appropriated and carried away by the oxygen, but which in the plant is absorbed and carried into the system. There is, however, another special arrangement for accomplishing this end in the best way. Instead of the fluid being carried up on the outside of the stem, as it is on the exterior surface of the copper wire, and where in the plant it would speedily be dried up by the sun and the wind, provision is made for its passing up inside among the cells and tissues within. Procure a few seedlings of any kind, from a half to an inch or more in length, and wash them for a minute or less in water coloured with a few drops of Judson's magenta dye, and then having rinsed them in clean water place them in a drop of water between two pieces of glass, and if they be now examined with a pocket lens it will be seen, that whilst the stain has almost instantly coloured the roots strongly, the colouring ceases abruptly at the neck or collar, and is then only very slowly absorbed in streaks and lines into the stems and leaves. There will thus be an abrupt division between the parts within the soil on the one hand, and those above it exposed to the atmosphere on the other. This process of staining is a most delicate test for chemical affinities or otherwise of electrical condition. The dye takes readily in all negative fluids, whilst it is rejected by all such as are positive. Let it be applied to the seed in its earliest stages of germination, and it will be found to be equally demonstrative, showing that the seed has a polar construction, and hence it is that it was enabled in the experiment with Cress seed to respond to the electric influence when reversed, and was thus compelled to an inverted position, or heels upwards. The roots are here shown to absorb readily an oxygenated pabulum and to pass it onwards; but the cross-action at the collar causes it to unite with other matters thus introduced and to become nutrient sap, so that it thus leaves this part in a different state to that in which it entered at the roots. If a seedling be grown in sand or in crushed brick, its rootlets when pulled up will be found clinging to the grains in clusters. Liebig has spoken of stones found in Wheat fields whose surfaces are covered with minute grooves, and in some instances near the roots of trees these grooves have been occupied by rootlets. Now these rootlets are strictly feeding upon the mineral, and have been the agents in electro-chemically dissolving out the said grooves. Flint glass and the most insoluble substances can be acted upon thus very readily by the battery, and when it is remembered that many or most of the tissues of plants are thickly studded with crystals of lime, or "raphides," and the stems of canes and grasses are covered with a coating of silex or flint, it is easy to see where and how the plant has acquired them.

Place a strip of bone, such as the handle of an old toothbrush, in acid instead of the copper wire, and it will undergo a very similar change. The lime will soon begin to appear above the acid, and crystallise upon the exposed surface. But there is another peculiarity. On the side away from the light the lime will travel much higher up than it does on the side exposed to the light, a fact quite in accordance with Nature. Oxygenation and the production of sap, or in fact the growth of a plant, takes place chiefly at night or in the dark, just as the digestion of our food and the production of chyme, manufactured in our stomachs, is carried on in the dark.

But to have a more perfect imitation of plant crystals take a small strip of sheet zinc and solder it on to the end of a similar piece of sheet copper, and immerse the zinc end up to the joint in a solution of chloride of lime, and the copper will soon become studded with minute acicular crystals, exactly similar to others to be found in plants. If the sap be viscid the crystals assume a globular form, and are then termed "spheraphides." These have been produced electrically in great abundance by using white of egg to thicken the solution. Such, then, being the means provided for the preparation of the plant's food at one end, the next point will be the consideration of those arrangements which effect its conversion at the other end into the various products and tissue of the system.—W. K. BRIDGMAN, *Norwich*.

Errata.—Page 304, eighteenth line from the bottom, first column, for "3d. per foot run" read 9d.; page 305, twenty-eighth line, first column, for "nitrogen" read "hydrogen."

THE STAPLEFORD ROSES.

I THINK "D., Deal," on page 299 too hasty in his conclusions about Mr. Bennett's hybrid Roses; there has scarcely been time to thoroughly ascertain their good or bad properties. The short time since these Roses were distributed, and their absence with the exception of one or two varieties from the various Rose shows of 1880, may afford some grounds for "D., Deal's," conclusions. I was more surprised when he stated that the heads of a well-known London firm should also speak against them. It seems strange that nearly all nurserymen, or their representatives, should praise these varieties so highly when first offering them, and then before being well known condemn them. I cannot say at the present that the Stapleford Roses will ever surpass such a variety as La France, which I consider one of the most useful Roses in cultivation.

"D., Deal," must bear in mind if these Stapleford Roses never become famous as exhibition varieties they may prove of much value for many other purposes. I do not altogether judge a Rose upon its merits in the exhibition tent as regards its form and beauty, but upon its general use for all purposes. What I have seen of the Stapleford Roses so far, they appear to possess advantages which will be highly prized by gardeners who have Roses to produce in quantity during the worst months of the year. No one can say they are not floriferous in their nature, every small shoot producing a bloom and continuing to do so in succession for months. Every small plant, when only 6 or 8 inches high, will commence flowering, and I believe when well tried these small plants will be most welcome amongst the many plants used for room decoration.—WM. BARDNEY.

KITCHEN GARDEN.

CLEAR off all exhausted crops so as to have the ground in readiness for digging or trenching, but where large fruit or other trees are growing in or near the garden it is well to defer turning up the soil until the leaves have fallen. Before digging or trenching, a dressing of quicklime at the rate of about a peck per rod will be beneficial in the destruction of slugs and their eggs. Manure, except in a crude state, is best applied in early spring, especially for trenched ground. Trenching should be practised not more distantly than every third year, and when the soil is of a retentive character it should be turned up in ridges of about 2 feet at the base, so as to expose as much surface to the action of the atmosphere as possible during the winter.

Root Crops.—The main crops of Carrots, Salsafy, Scorzonera, Beet, &c., should now be taken up on a dry day, and placed in an airy shed to become moderately dry before storing away in moist sand in a cool place. Do not pare the tops too closely, and in taking up Beet be careful not to cut or break any of the tap roots, as in that case the colour will be much deteriorated when cooked.

Cauliflowers will now require considerable attention to protect the heads in case of sudden frosts; sufficient at present will be attained by breaking down a few leaves over those most advanced, and it assists in keeping the heads clean and white. Complete the planting of Cabbage for spring use, and a number of strong plants placed a foot apart on a warm border will come in early and prove useful as

Coleworts. Early crops should have a little soil drawn around the stems to steady them against wind, also dusting with lime or soot as a deterrent to slugs.

Forcing Department.—A hotbed of fermenting material should at once be made about 2 feet in height, well trodden or beaten down, the frame being placed on, and the bed covered with about 4 inches depth of light rich soil. When the soil is warmed through sow Radish seed, and as soon as the seedlings appear above the surface withdraw the lights until the Radishes are well advanced in growth, when they will bear being kept closer. Wood's Frame is the best long variety; Scarlet and White Forcing Turnip, with French Breakfast, are the best for forcing in pits or houses. Late crops of French Beans in pits or frames will require considerable attention to prevent them damping off, ventilating constantly, maintaining a temperature of 60° to 65° at night and 70° to 75° by day. Make successional sowings in 9-inch pots, employing rather light rich soil, and keep the pots well up to the light. Commence periodical sowings of Mustard and Cress. Where Seakale is required very early, strong plants with well-developed crowns may now be lifted and have the leaves carefully stripped off or cut-in with a knife, placing the roots in rich moist soil in a Mushroom house or similar place where there is sufficient heat and means are taken to exclude light. A fermenting bed will facilitate the growth, the top heat ranging from 60° to 65°.

FRUIT HOUSES.

Melons.—The season, as regards dung-heated pits and frames, may be considered at an end; we may therefore dispense with any further instructions in this department for the present. To have Melons late plenty of both top and bottom heat must be at command, and where these exist Melons will still form part of the dessert. Atmospheric moisture will require to be sparingly furnished after this, especially in dull weather, affording very moderate supplies of water at the roots, about once a week being often enough. Remove all superfluous laterals and thinning out the old growths and foliage, so as to give the fruit the benefit of the autumn sun. A temperature of 70° to 75° should be maintained artificially, falling to 65° at night. As opportunity offers a quantity of rather strong loam cut with its turf about 4 inches thick should be secured and stacked grass side downwards, adding about a bushel of quicklime to every ten of loam. This allowed to lie over winter will be an excellent compost by the time it is required in spring. Cow dung, if it is likely the loam will need enriching, should be collected and kept dry.

Cucumbers.—Place out the plants intended for winter fruiting at once on raised hillocks or ridges as near the glass as the form of the house admits. Let the autumn-fruiting be regularly cut over twice a week, removing all tendrils and male blossoms, maintaining a night temperature of 75°, falling to 65° in the morning, 70° to 75° artificially in the daytime, and 80° to 85° with sun heat, admitting a little air upon all favourable opportunities. Continue keeping the evaporation troughs filled, and damp the floor at about 7.30 A.M. and 3.30 P.M., ceasing syringing over the foliage now; and if mildew appear dust well with flowers of sulphur, fumigating if aphides are seen. Reduce the supply of water at the roots, but not so much as to cause flagging. Keep the glass thoroughly clean to admit all the light possible.

Cherry House.—The lights which were removed need not be replaced for another month or six weeks; in the meantime have them repaired and painted. If any removal of the trees be intended it should be attended to as soon as the leaves commence falling. Trees not in a satisfactory condition should have their roots examined, and the soil must be removed, carefully lifting the roots to within 2 or 3 feet of the stem, and, after seeing that the drainage is in good order replace them with as little delay as possible in fresh compost. Turfy loam, with about a sixth of road scrapings and a twelfth of old mortar rubbish forms a suitable compost. It should be employed rather dry and rammed well down, giving a good watering at once. If fresh trees have to be introduced select those that have been trained to a wall for about four years, and if carefully lifted and planted they will give good results the first season. The varieties most suitable for growing under glass are Black Tartarian, May Duke, Elton, Governor Wood, and Frogmore Early. It is essential that the border be

efficiently drained, and above them 12 inches of rubble, covered with a layer of turves grass side downwards, and about 24 inches of compost as above described, allowing 9 inches more for settling. A border 6 feet wide is ample, and should be entirely within the house. Trees in pots must be examined, and such as require larger pots can be shifted into those 2 to 3 inches larger. Where it is not considered desirable to increase the size of the pots the trees should have a few inches of soil removed from the base of the balls, the roots being cut back, and all the loose surface soil removed; supplying fresh soil, to which has been added about a fourth of well-decomposed manure. Water thoroughly, and plunge the pots in ashes to the rims in a sheltered situation, where they may remain until removed to the house.

ORCHARD HOUSE.

The trees having been attended to in potting or surface-dressing as may be required, they should remain under glass until most of the leaves have fallen, when they may be moved into the open air, placing them on ashes in a sheltered situation, surrounding and covering the pots with that or some other protective material. In this position they may remain until December or January, the trees being benefited by the exposure. If, however, potting and surface-dressing has been delayed it should be attended to at once. Trees allowed to root from the base of the pots should have the roots cut off close to the bottom of the pots, and the surface soil with the roots or fibres it may contain must be scraped out to a depth of at least 3 or 4 inches at the sides of the pots, and supply turfy loam rather strong, adding a fourth of well-decayed manure and a twentieth of bone meal, which can hardly be rammed too firmly. Planted-out trees requiring root-pruning should be attended to whilst they are in leaf, and those not thriving satisfactorily may have the roots laid bare, the old soil removed, lifting the roots carefully to within a short distance from the stem, the drainage being put right, and the trees replanted in fresh compost, spreading the roots out carefully. Maiden loam, strong rather than light, suits all fruit trees. The ventilators must be kept open by night as well as by day, but in case of the wood not ripening well the ventilation may be lessened in the daytime to secure a higher temperature, allowing, however, a circulation of air, and ventilating fully at night. If there is means of heating, the heat may be turned on in the morning and off at night.

FLOWER GARDEN.

The late tempestuous weather has nearly destroyed the beauty of flower gardens, hence anything that it is desirable to protect should at once be attended to. Some of the plants now employed for outdoor decoration are of great value for furnishing conservatories, halls, &c., provided they are lifted before they become damaged. Aralias, Abutilons, Chilian Beet, Cannas, Dracænas, Melianthus, Solanums, Grevillea robusta, Acacia lophantha, Wigandias, &c., lifted carefully with good balls, potted, and placed in a close moist atmosphere, and if syringed they will soon become well established and prove useful for general decoration where it would be running great risk to employ choicer but not more effective plants. Succulents of the half-hardy type, such as Aloes, Agaves, Echeveria metallica, E. metallica rubra and E. secunda glauca, Sempervivum tabulæforme, S. arboreum variegatum, S. canariense, S. Donckelaari, Kleinias, and Pachyphytums, should at once be taken up, potted in good open soil, and placed in a dry warm house or pit until established, when they may be moved to cooler quarters with advantage. All Pelargoniums when housed should have a dry atmosphere, damp being their greatest enemy. Verbenas, Calceolarias, Petunias, and similar plants will do well in a light airy house where the temperature is not allowed to fall below freezing point. Alternantheras, Coleus, and Iresines should have a minimum temperature of 55° to winter them satisfactorily.

As soon as the frost causes a general lifting of stock, a speedy clearance should be effected preparatory to filling the beds for the winter, either with spring-flowering plants, bulbs, or evergreens. Of shrubs suitable for this purpose may be mentioned Erica herbacea carnea, E. herbacea alba, Laurustinus, Andromeda floribunda, A. Catesbæi, Euonymus radicans variegatus, E. japonicus albo-marginatus, E. japonicus aureus and aureus marginatus, Aucuba japonica limbata, A. longifolia, A. japonica vera nana, A. japonica mascula,

Cryptomeria elegans and var. nana; Hedera arborea vars. aurea, elegantissima, Rægnieriana, and fructo-luteo; Osmanthus ilicifolius and vars. aureus and variegatus nanus, Skimmia japonica, Thuja aurea, Thujopsis borealis, Retinospora plumosa and var. aurea, R. obtusa aurea nana, R. ericoides, Pernettya mucronata; Cupressus Lawsoniana and vars. nana glauca, alba variegata, and erecta viridis; Ligustrum japonicum, Juniperus Sabina variegata, Myrtle-leaved Portugal Laurel, Buxus suffruticosa argentea marginata nova, B. sempervirens aurea, Vinca elegantissima, Gold and Silver Hollies, and Golden Yews. Grounds, lines, or edgings of Gold and common Thyme, Pyrethrum Golden Feather, Ajuga reptans rubra, Stachys lanata, Cerastium, Sedum corsicum and S. glaucum, Sempervivum arachnoideum, S. calcareum, and S. montanum, and Saxifraga granulata and hirta, will render the garden cheerful in the duldest months; and if some of the earliest flowering bulbs, as Snowdrops, Seillas, and Crocuses, with Arabis alpina variegata argentea, Hepaticas, Daisies, Primroses, &c., be introduced a very effective spring display may be secured. Beet and the many coloured variegated Kales may be used with good effect.

The mixed or herbaceous border should now be examined, and any of the strong-growing plants having outgrown the spaces allotted to them they should at once be reduced. Most herbaceous plants require good soil, and where any have stood long on the same ground an entire removal and replanting will be found of great benefit, as the strong-growing species soon exhaust the soil immediately surrounding them. By replanting early in the season the plants have time to become re-established before severe weather sets in. Prior to replanting the border should be trenched as deeply as there is good soil, and at the same time adding some well-decomposed manure, leaf soil, or well-reduced vegetable soil, working it well in.

Planting evergreens may be done now, also deciduous trees and shrubs as soon as the foliage begins to fall; and the ground being comparatively warm and moist the plants will commence making roots at once, which cannot be the case when deferred until the ground is cold. All alterations should be pushed forward at this season instead of putting it off until spring, when more important matters will be pressing. Sweeping and cleaning up will entail constant labour for some time to come.

PLANT HOUSES.

Greenhouse.—A few plants of Cytisus racemosus superbus that have been ripened well and early, if now introduced to gentle heat and kept near the glass, will come into flower quickly, and be very useful for conservatory and cutting. Some of the earliest Epacris may be forwarded by placing them in a house with a temperature of 50°, and a similar temperature will be required for Monochætums that have well ripened through the autumn, and will shortly flower. Lasiandra macrantha floribunda, to induce it opening its violet-purple flowers freely, should have similar treatment, also Tree Carnations, Libonia floribunda, Cyclamen persicum vars., and Bouvardias, as they do not flower freely in winter in an ordinary greenhouse temperature. Witsenia corymbosa will now be opening its lovely blue flowers, and as its leaves are inclined to become bad at the points these should be removed with a sharp knife so as to improve its appearance for the conservatory. Heliotropes that have been well grown and fully exposed during the summer, with the flowers constantly pinched off, will flower for a considerable time in a temperature of 45° to 50° artificially. Crowea elliptica, C. latifolia, C. saligna, and C. stricta, bloom for six weeks to two months continuously at this season, their starry pink flowers being very pretty, and if kept rather warmer than an ordinary greenhouse their flowers will be finer. Correa cardinalis, C. Brilliant and C. bicolor, will bloom with little attention to the end of the year, also many Ericas. Laehenalias will now be growing, and should be potted and assigned positions near to the glass.

Orchids.—Many attractive species and varieties will yet be blooming, and the practice of removing them to a drier atmosphere should be followed, the temperature ranging from 50° to 55°, the flowers lasting longer than in a very moist atmosphere. Oncidium macranthum, O. flexuosum majus, O. tigrinum, O. incurvum, O. aurosum, and O. bicallosum are among the best for autumn and winter flowering.

Vanda cœrulea, Odontoglossum grande, and Pleiones can bear a dry cool temperature, giving them just enough water to prevent the plants from suffering, thus prolonging the blooming period. Calanthes now throwing up their flower spikes should have every encouragement of heat and moisture, keeping the leaves clean by frequent spongings. Dendrobiums and Cattleyas which have completed their growth will now require very little water. Phalaenopsis must be very carefully supplied with moisture, for should the leaves be overcharged at this season they are very liable to decay. Zygopetalums starting into growth should be repotted, the pots being three parts filled with potsherds, filling up with good rough peat, and growing in a moist atmosphere. The temperature of the East India house should have a mean of 70° by day and 60° at night; the Cattleya house 65° by day and 55° by night; and the Odontoglossum house 55° by day and 45° by night. The atmospheric moisture must also be reduced, and syringing overhead discontinued, except to prevent shrivelling, and for newly imported plants. Very little ventilation will now be necessary except when mild, when a little air may be given. Let the woodwork and glass be thoroughly cleaned, taking advantage of every opportunity to give the plants a thorough cleaning. Slugs are very destructive to the growths and roots, they should be sought after with a lamp at night. Plants sometimes become shrivelled from the roots decaying, in which case shake out and cut away all dead roots, washing the remainder with tepid water, repotting and giving very little water until fresh roots are pushed, keeping a moist atmosphere and syringing frequently. Syringing will be all that is necessary to restore shrivelled pseudo-bulbs to plumpness, the roots being healthy, but water lightly at the roots.

TRADE CATALOGUES RECEIVED.

William Paul & Son, Waltham Cross, Herts.—*Special Catalogue of Roses, Fruit Trees, Shrubs, &c.*

Cranston's Nursery and Seed Company, King's Acre, Hereford.—*Catalogue of Roses.*

Boulton & Paul, Norwich.—*Illustrated List of Ornamental Iron Fences and Gates.*

Osborn & Sons, Fulham, London, S.W.—*List of Trees and Shrubs.*

John George Hill, Merriott Nurseries, Crewkerne, Somerset.—*Catalogue of Fruit Trees, Nursery Stock, and Bulbs.*

John Jefferies & Son, Cirencester.—*Catalogues of Roses, Trees, and Shrubs.*

** All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Apples for Orchard (*P. Gravel*).—If you will state the number of trees respectively of dessert and culinary varieties that you require, and the district for which they are intended, we will publish a suitable selection.

Leucadendron argenteum (*John Sheppard*).—The silvery leaf you sent is that of the handsome Silver Tree, or Leucadendron argenteum, of the Cape of Good Hope, where the colonists also know it as the Witteboom. The tree was at one time in great request there to furnish a supply of firewood, and that led to the destruction of so many that it is now comparatively scarce.

Tropæolum speciosum (*P. P., Dublin*).—We know of no reason whatever "why this plant will not succeed in Ireland," and your failure to establish it does not prove that it will not grow there. We think there are plants growing in Ireland, and we know many persons have failed to establish it in England, while several have succeeded, and the plants grow and flower freely. It appears to like a cool position and an abundant supply of water.

Name of Tree (*Winchester*).—Please send us another spray, and also leaves of the different forms to which you first alluded; none of those sent were lobed. We think on examining the leaf variation we shall be able to give you the correct name and some information relative to the tree.

Camellia Culture (*D. T.*).—There is no pamphlet published on Camellias. If you send 3½d. in postage stamps to this office, and ask the publisher to send

you No. 994 of the Journal, you will find notes on their propagation and culture that will possibly be of service to you. If you need special information on any particular point relative to these plants we will readily supply it through our columns if you will state your requirements fully and clearly.

Wintering Alternantheras (*Kingston*).—You cannot preserve them in your cool greenhouse from which "frost is only just excluded." They are stove plants; and like many others that must have a warm house in winter, Colenses for instance, they succeed well in the open ground in summer. A temperature of 60°, or 55° as a minimum, is essential to the preservation of Alternantheras through the winter.

Anemone japonica (*A Subscriber, Warwick*).—The plant to which you refer was probably a chance seedling, and there is considerable variation both in the size and shades of colour of plants raised from seed. We have seen many flowers as deep in colour and better in form than yours; still the variety is a very pretty one and worthy of preservation.

Grapes not Colouring (*J. E.*).—The great number of small berries indicate that the flowers were imperfectly fertilised, possibly owing to a low temperature and moist atmosphere during the flowering period, which prevented the dispersion of the pollen. Want of colour is generally the result of overcropping. The "black stalks" to which you allude indicate that the Grapes are shanking, which is frequently induced by overcropping or defective root-action. Not knowing the age and condition of the Vines, with the weight of the crop on each rod, we are unable to give a more explicit reply.

Rose for Wall (*Stirling Castle*).—Few Roses give more satisfaction for covering space on a wall than Gloire de Dijon, which flowers early and late, and occasionally produces blooms suitable for exhibition. If you prefer a dark Rose probably Duke of Edinburgh will suit you. It is a free grower, and affords richly coloured blooms, several of which under good cultivation are fine for exhibition. Charles Lefebvre is also a good pillar and exhibition Rose. The Pear sent is the English Caillot Rosat, the Apple Gloria Mundi. It is good, but we have received some larger specimens this week. Your Lord Suffield is above the average, but we have seen larger examples.

Camellia Buds Abnormal (*J. C.*).—The plant was either too exhausted by excessive flowering last year or its roots received a check, possibly by drought, at the period when fresh growth was being produced. If all the growth terminals are similar to the one you have sent the plant will not recover without some pruning, or at least it will be brought into a satisfactory condition much sooner by the judicious aid of the knife. All the shoots should be shortened to parts where healthy buds are apparent; and if there are no such buds we should cut the plant down much after the manner of pruning a Pelargonium, as no plants break more freely from the old wood than do Camellias. The pruning should be done in spring, and the plant placed in a warm moist house and be syringed frequently, when it will in all probability produce fresh growth freely, and become as healthy and vigorous as a young plant.

Inarching Vines (*Correspondent*).—We would rather inarch or graft the Madresfield Court with the Buckland Sweetwater than the Gros Colman, as on the latter, which is a very strong grower, the Grapes might be liable to crack. The Duke of Buccleuch we should inarch with Gros Colman, and the Canon Hall Muscat with the White Tokay. We cannot account for the unpleasant flavour of your Grapes except on the supposition that you have watered the Vines with liquid manure after the Grapes commenced ripening. This does not always affect the flavour, but it does occasionally, and the practice is not a safe one, and is not adopted by good cultivators.

Hautbois Strawberry (*Tyro*).—The old Hautbois is a very small fruit, pale in colour and with prominent seeds, and has the peculiar flavour of the wild Strawberry of the woods, *Fragaria vesca*. It is scarcely worth cultivating. Prolific Hautbois is larger with purplish fruit, and is richer in flavour. The Royal Hautbois is much larger than either of the preceding, the fruit being rosy purple in colour and rich in flavour. It is by far the best variety of Hautbois. You say the Hautbois is not so "much as mentioned" in the work you quote, but if you look carefully you will find it under the name of *Fragaria elatior*. All the varieties of Hautbois are totally distinct in appearance and flavour from the ordinary dessert Strawberries, and are much smaller. The peculiar flavour is agreeable to some palates, but not by any means to all. You had better obtain a dozen plants of the Royal Hautbois, and try the fruit before planting the variety extensively. We can only answer your second letter through the post, and for this purpose your full address is essential.

Trees for Churchyard (*A Yorkshire Curate*).—We apprehend that you require evergreen trees for your churchyard on the East Yorkshire coast, as those you have tried are Conifers. *Thujaopsis borealis* (*Cupressus Nutkaensis*) is a most graceful Conifer of erect habit, forming a beautiful conical tree, very hardy; indeed it is never injured by frost, and is naturally a coast tree, being found on the north-west coast of North America—viz., Nootka Sound, Observatory Inlet, and on the island of Sitka. It emits a fine balsamic odour, and is the tree of trees for your purpose, and we should employ it exclusively. *Pinus pumilio* is a trunkless spreading bush, very hardy, and is from the Alps beyond the highest limit for growing trees. *Pinus austriacus* forms a dense spreading tree, and sombre in aspect. *Pinus insignis sempervirens* is also very valuable for seaside planting. Of deciduous trees the Red-twigged Lime (*Tilia sanguinea*), *Ulmus campestris*, *Ulmus campestris fastigiata*, Beech common and weeping, *Platanus occidentalis*, and Weeping Birch. Evergreen Oaks also succeed well, but are liable to have the leaves browned.

Flowers for Front Garden (*A Reader*).—If Roses thrive in your district you might have a half-standard in each bed, La France and Général Jacqueminot being good garden varieties. No flowers succeed better in towns, and none are more suitable for mixed beds than the old scarlet Glove, the flowers of which are both beautiful and sweet. White and other common Pinks would also be suitable. Perennial Candytufts would precede these. Sweet Williams are excellent for small mixed beds, and are readily raised from seed sown in the open ground in June, so also are Antirrhinums, two or three plants of the flowers named to be planted towards the centre of the beds; and nearer the margin Pansies and Polyanthus, which also may be raised from seed, and still closer to the edge double Daisies and Thrift. Those would do as permanent occupants; between them a few Stocks and Asters planted in May, and seeds of annuals sown in March and April, such as Mignonette, Nemophilas, Saponarias, dwarf Convolvulus, Lupins, and Clarkias, with a patch or two of *Linum grandiflorum* and Venus's Looking-glass, would render your beds both gay and sweet. For flowering in autumn plant *Anemone japonica* with its variety alba. For such gardens bulbs are indispensable; and Winter Aconites, Crocuses, Snowdrops, Tulips, Hyacinths, and *Anemone fulgens* should be planted at once. If stout neat pegs are firmly inserted to mark the positions of the bulbs, these may remain in the beds as permanent occupants, and the soil being suitable they will grow and flower each year.

Small's Admirable Apple (*G. B. V., Co. Down*).—In all probability the very mode you have adopted to render the tree fruitful has had an opposite effect. You say you have "pruned regularly summer and winter," and yet your tree produces little blossom. We advise you to try another mode. Thin out the branches if crowded, and do not prune at all except to prevent overcrowding of the growths. This Apple has a tendency to produce blossoms on the ends of the shoots. We have seen trees that have been pruned systematically comparatively barren, while others that were seldom touched with the knife laden with fine fruit. It is a very good Apple.

Wireworms (*Under Gardener*).—You have been rightly informed that "the wireworm is not a worm at all, but the grub of a beetle." This beetle is called *Cataphagus lineatus* by some entomologists, and *Elatér segetis* and *E. striatus* by others. It is very appropriately called *Cataphagus*, from the Greek word signifying to devour, and *lineatus*, or lined, from the brown lines along its wing-cases. The larva, or wireworm, of this beetle is a pale dirty orange or tawny colour, having six very short legs. The body is formed of twelve scaly rings besides the head. Two different kinds, the offspring probably of different species of this genus of beetle, are represented in the annexed cut. In the same appears the *C. lineatus* magnified, and the line by the side shows the natural length of the insect. It is of a dull brown colour, with a greyish down over it; head and thorax black. The lines on the wing-cases are in pairs, united at each end, and the legs and antennae dull red. The beetle may be found under moss in hedges and elsewhere throughout the year. Its larva preys upon the roots of almost all cultivated plants. In the garden those of Lettuces, Turnips, Carrots, Potatoes, Cabbages, Irises, Pinks, Lobelias, Anemones, Ranunculuses, Carnations, and

Fig. 67.

many others are destroyed by this vermin. Digging gaslime into the soil has been recommended for driving it away, and the root of the white Mustard is said to have the same effect. Other remedies are to grow plants for which they have a greater fondness near those we wish to protect. The roots of the double Daisy are such a lure for them, and from a row of these grown to protect Carnations, &c., two thousand wireworms are recorded as being taken in one season. Soda ash dug plentifully into the soil is also said to destroy them, but their most effectual exterminator is the mole.

Planting Tulips (*J. E. D.*).—The best planting season is about the beginning of the second week in November, as near the 9th of that month as the weather and the state of the ground will permit. This rule applies to all the country north of London; perhaps in the milder climate of the southern counties a week later would be better. Offsets may be planted a little sooner or later, as may be convenient. The tallest growers should be in the centre of the bed. This renders it necessary to plant them in rows lengthways of the bed, and not across it. This being determined upon, let the soil be levelled, then with a hoe draw a drill the length of the bed as nearly 2 inches deep as possible. As soon as the drill is drawn bring out all the tall growers, and plant them 5 inches apart at the bottom of the drill, giving each a gentle pressure. When the row is finished thrust in at each end a strong stick to mark where the row of bulbs is when covered up. Cover up the bulbs by the aid of a short-toothed rake. After that let the soil on each side of the planted row be stirred up with a three-pronged fork. Then set the line at the right distance from the centre (we mentioned that the beds should be 4 feet wide, which would allow 9 inches between each of the five rows, and 6 inches next the edging); the line then must be set at such a distance from the centre that the next row of bulbs will be exactly 9 inches apart from the centre one. Draw the drill the same depth as the first, and plant the next tallest flowers in it. Then mark the row with a stick at each end, and so proceed till the whole is finished; the lowest growers will then be next the paths all round the bed. Each variety must be numbered.

Early Cucumbers (*C. S.*).—You ought to have been more explicit in your inquiries with regard to the "best time to start Cucumbers and Tomatoes for fruiting in March," as so much depends upon the means at your command. Supposing you have a Cucumber house with the proper amount of top and bottom heat, the seed may be sown during the first week in January. It would germinate if sown earlier, but the seedlings obtained would, during the dull midwinter months, become drawn and weakly, and be more liable to be infested with red spider and other insect pests than are those raised at the time named and grown without any check. The Cucumber seed may be sown singly in 3 inch pots, using light loamy soil, and plunged in a brisk but not over-moist bottom heat, as excessive moisture, either from the bed or administered, will destroy the seed. The seedlings should receive as much light and air as possible, and will require to be lightly supported with stakes. In order to have them as strong as possible at planting time, shift them into either 6-inch or 8-inch pots, and from these transfer to beds or heaps of soil previously prepared, so as to become thoroughly warmed, performing the operation in each instance before the plants are much root-bound. The subsequent treatment given being favourable, no difficulty ought to be experienced in obtaining fruit, say about the middle of March. It is a mistake, however, to force very hard or to crop young plants heavily, both being very weakening in effect and tending to shorten the duration of the crop, the ultimate gain thus being very doubtful. The most popular variety with the market growers is Rollisson's Telegraph; and another very prolific and suitable variety is Kelway's Paragon.

Early Tomatoes (*Idem*).—To have ripe Tomatoes in March you ought to have strong plants well and finally established in either beds, boxes, or large pots (giving the preference to the latter for early work) by the first week in January. These should be kept growing briskly, the pots being near to the pipes, and the temperature of the house ranging from 60° to 65° by night, and 10° higher in the daytime. Train to single stems, rub out side shoots, carefully impregnate the first blooms, give abundance of liquid manure, and cut the fruit on the first signs of cracking. If these strong plants are not to be had, do not attempt to secure ripe fruit in March; far better will it be to sow early in January, and thereby secure strong plants from which heavy crops may eventually be taken during April and May. For treatment of these see reply to "R. D.," page 269 of this volume. Hathaway's Excelsior and Earley's Defiance are two very suitable varieties for the work. Conqueror is a very heavy cropping variety, but the colour, unfortunately, injuriously affects its sale. If, however, it is really imperative that ripe Tomatoes be had in March, we should advise the attempt being made with one of the smaller varieties, of which probably the best is Vick's Criterion. From single plants of this variety fruited in 8-inch pots comparatively heavy crops may be taken, which need not, and in your case should not, interfere with the growth of the main crop of heavier and more saleable varieties.

Early in December, or even earlier, sow seed thinly in well-drained 6-inch pots, using light sandy soil and plunging in heat if possible till the seeds have germinated. Before the seedlings are much drawn transfer them to warm shelves near the glass, and when in rough leaf pot off singly in 3-inch pots, placing the plants down the sides of the pots and carefully filling in the soil up to the seed leaves. If returned to bottom heat they will more quickly recover, but should, as soon as this is found to be the case, be again placed on the shelves, the aim being to keep them sturdy. When well established shift them into the fruiting pots. The soil used may consist of two parts of turfy loam to one of well-decomposed manure, which previous to using should be thoroughly warmed. From this time the best place to grow and fruit them is on the front staging near to hot-water pipes. Train to upright stakes, rub out side shoots as they appear, and stop beyond the third cluster of bloom. When the bloom is set give moderately strong liquid manure at each watering. These miniature varieties, are well adapted for growing on the end stages and back shelves of early vineries, Peach, and other forcing houses.

Names of Fruit (*F. D., South Wales*).—The Pear is Caillot Rosat. (*G. B. C.*).—The Plum is Sandall's, a variety much grown in the market gardens of Middlesex. It certainly is not what it was intended for. (*K. E.*).—1, Waltham Abbey Seedling; 2, Holland Pippin; 3, Old Orange Pippin; 4, Lewis' Incomparable; 5, Norfolk Bearer; 6, Loan's Pearman. (*W. A.*).—Red Autumn Calville. (*H. J. F.*).—Tower of Glamis.

Names of Plants (*W. K. B.*).—The spray was much crushed, but we think the *Bouvardia* is *Humboldtii corymbiflora*. *B. jasminiflora* has much larger flowers, at least when the plant producing them is well grown. (*W. C. B.*).—1, *Pleopeltis percuta*; 2, *Gymnogramma L'Herminieri*; 3, *Platyloia rotundifolia*; 4, *Gymnogramma peruviana argyrophylla*; 5, *Selaginella caesia*; 6, *Davallia dissecta elegans*. (*Newton, Bristol*).—*Tacsonia mollissima*. (*O. P.*).—1, Quite insufficient for identification; 2, *Fuchsia microphylla*; 3, *Polystichum angulare*; 4, Probably *Escallonia macrantha*, but specimen very small. (*G. B. C.*).—1, An *Asplenium*, but the specimen was so very stunted and imperfect that its name could not be determined; 2, *Adiantum macrophyllum*.

POULTRY, PIGEON, AND BEE CHRONICLE.

ROTATIONS FOR CROPPING LIGHT SOILS.

(Continued from page 338.)

WE have referred to the rotation of cropping a light land chalk hill farm with water meadows, &c., attached, and calculated for keeping a large breeding flock of sheep. We will now consider a farm without meadows, and consisting of arable land only, but situated amongst the chalk hills. We will discuss the system of cropping adapted to it when cultivated with the view of maintaining a large flock of breeding ewes or of store wether sheep. To illustrate the rotation of cropping, &c., we will again describe a farm of 450 acres, and as there will be neither meadows or down land for the sheep to fall back upon at certain times of the year we must make it a four-course rotation, excepting 50 acres, which will be laid into Lucerne and Saintfoin; 10 acres to be laid down with Lucerne for a permanency, and situated nearest to the farm premises; also 40 acres to be laid into Saintfoin for four years, which will then be broken up for tillage, and exchanged for the same extent of land taken out of one of the Grass or Clover lays of the rotation. We have then to deal with 400 acres of arable land. 1st course, Wheat; 2nd, green crops and roots; 3rd, Lent corn; 4th and last course, Clovers and Grass sown in the Lent corn. Now, one of the chief features of this rotation is the adoption of the growth of Lucerne and Saintfoin, which must be considered practically as the substitute for meadows and down land. The first course will consist of 100 acres of Wheat, the preparation for which will be described more particularly in the last course. The second course will also consist of 100 acres, 50 acres of which will be cropped with green fodder crops, such as Rye, Trifolium, Vetches, &c., followed by Swedes and common Turnips. The other 50 acres of the foulest land will be autumn-fallowed, so that the seed for root crops, especially Mangolds, may be drilled without spring ploughing—not only because the seed may be gathered earlier, but because the working of the scarifier only in the spring retains the moisture, so essential to the

successful growth of roots upon such light dry soils as compose the chalk hill farms.

The feeding off these root crops in good time is of the highest importance, in order that the Lent corn may be sown early, which in the case of a dry flock like wether sheep may easily be done, because larger numbers may be kept for a time, and then the numbers of the stock may be adjusted by sale to the food. Not so with the breeding flock, in consequence of its being necessary for a profitable result to retain the lambs and off-going ewes until certain periods of the year when they are at maturity for the markets in which they are to be sold. On some chalk hill farms at a great elevation, or more than usually exposed, it will be necessary to leave out the Mangold crop, because under such circumstances, particularly in the north midland and western counties, it cannot result in a full crop. We have therefore to recommend that, in the absence of Mangold, Swedes be substituted in the root lain, of varieties which will not only stand the winter without injury better than many others, but can be preserved to a later period in the spring—namely, the green, white or bronze varieties. Either of these will do when we can obtain them of a deep yellow colour inside and a clean growth, for if the seed is sown after the 10th of June they will retain their feeding value under treatment during the last half of the month of April and the first half of the month of May, which is a matter of so much consequence that we have on various occasions resorted to the plan of crowing down, after the greens have run up about 12 or 15 inches, by cutting off these close to the root. In this way we have retained the roots in the land into the month of June; nevertheless, if a full stock of ewes and lambs are maintained on the farm the lambs, when allowed to run in advance of the ewes, will sometimes pick off the greens and keep the roots in good feeding condition without extra labour. About 10 acres of Swedes reserved in this way will enable all the Lent corn to be sown in good time, and will only diminish the lain to 90 acres; we have therefore, after the Swedes are fed off, to crop this 10 acres in another way, and so that it may fall into the Wheat lain in the next year. Our plan is, as fast as the Swedes are fed off to plough and sow immediately a mixed crop of 1 lb. of Rape seed and 2 bushels of Italian Rye Grass seed of foreign growth per acre, mixed and sown broadcast. We prefer this plan to sowing Turnips after the Swedes, because this Grass and Rape will give abundance of food in the autumn, winter, and in early spring, after which it is laid up and cut for hay, then ploughed, and pressed, and drilled with Turnips to be fed off, and the land sown with Wheat.

The third course will be Lent corn, &c., 100 acres, 90 of which will be seeded with Clover and Grasses in the Lent corn, 50 acres with Red Clover Alsike and Giant Saintfoin for hay, and 40 acres with Dutch Clover and Italian Rye Grass for feeding, this seeding to be reversed in the next rotation. The Clovers, &c., will be cut twice for hay, and the land be dunged and sown with Wheat after one ploughing and pressing. The 40 acres sown with Dutch and Italian Grass will, together with the 10 acres of Grass and Rape above alluded to, make up 50 acres, to be ploughed and pressed at midsummer, and sown with Turnips to be fed off by sheep, a liberal dressing of superphosphate having been drilled with the seed, and a good allowance of cotton cake allowed the sheep whilst feeding will not only answer the purpose as profitable management of sheep, but will be a judicious mode by which the land is made rich enough to carry a full crop of Wheat, the whole of the farmyard and stable manure having been applied to the 50 acres of Clover lain. Thus it will be clear that we have 190 acres of cereal crops, and one of the largest provisions for a breeding flock of sheep which can be advised upon a cold hill farm of the given area or farm of 450 acres. The rotation as just concluded refers more particularly to a poor chalk soil in an elevated position.

We shall, however, now consider a rotation for a farm on a chalk soil, which although very thin and light is of a kind, soft, and malmy texture, and situated in the southern or south-eastern counties. We will again take a farm of 450 acres for illustration, although it actually represents the system pursued by one of the oldest and most practical farmers within our acquaintance. He follows a system peculiar to himself, whereby he is enabled to keep a very large quantity of stock, and to take three corn crops in six years. The foundation of his system is keeping the ground constantly in action, and growing great quantities of good sheep food whilst bringing the land into the best possible condition for cereal crops. This farm consists of 900 acres; but in order that the home farmer may more easily compare the system with those which we have given before, and those to which we intend to refer hereafter, we will take an acreage of 450 acres. On this farm is a capital pasture or down on the high ground, and the best managed of any we have ever seen, which is done

by taking the produce without close feeding on the open down system, the sheep being allowed only to feed on it within shifting folds, similar to the ordinary plan of folding off green crops or roots, and in this way the Grass is never eaten out so bare as to injure the herbage or finer Grasses. We will call this pasture 30 acres, which will leave 420 acres, which under a six-course will give 70 acres in each. The rotation may be described as—1st, Wheat; 2nd, Barley; 3rd, Turnips, Swedes, and other roots; 4th, Barley; 5th, Clover and Grass; 6th, old Clover and Grass lea. The courses or lains will then consist of 70 acres each. The first course Wheat will be sown after Clover and Grass having laid two years in part, the other part being after Turnips, grown after the Grass lea ground had been ploughed and pressed at midsummer, the Clover lea part being dunged from the farmyard, the other part being fed off with Turnips, and the sheep eating cake, corn, &c., then forms a full and well-tilled course prepared for Wheat. The second course is Barley, clean-ploughed and laid up for the winter, so that it may not require ploughing in the spring, the scarifier only being used to obtain a tilth, except in the case of a field being foul, it is then fallowed in the autumn. Now, the Barley grown is drilled with artificial manures, and yields corn of capital malting quality, and far better than it could be as a rule when taken after roots, because it can be earlier sown, but not on account of the treading of the sheep, for the soil we are speaking of does not suffer by treading, but rather the reverse. The third course will be root crops, the whole 70 acres being seeded in the autumn for green crops, such as Rye, Trifolium, and Winter Vetches; these after being fed off by sheep eating cake, &c., upon the land, give a good preparation for roots, Mangolds following Rye, for it must be remembered that on this soil, the climate being favourable, Mangolds succeed very well. Swedes follow the Trifolium and the earliest-fed Vetches, the remainder being sown with hybrid and common Turnips. The fourth course is Barley, or the latest cleared land is sown with white Waterloo Oats or drege. Half this course is seeded with 8 lbs. of Broad Clover, 4 lbs. of Alsike, and 2 bushels of Giant Saintfoin per acre; the latter takes extremely well, in consequence of there being no regular Saintfoin course as pursued on some farms, and this mixture not only affords hay of capital quality, but an excellent layer for the second year. The half of the lain is sown with Dutch and Alsike Clover seed, in admixture with Perennial Rye Grass, Italian Rye not being approved on this farm, where constant feeding is going on, it being said that the sheep do not so well in feeding off the second and third foldings of Italian Rye Grass, and often refuse it. This is a strong argument against it, as in this case the Grass is fed off by sheep for at least eighteen months, and although it is not often done we think that Giant Saintfoin in mixture with the Grasses for feeding would be an improvement. It is, however, held that if Saintfoin formed part of the Grass seeding it would not take so well in the next course, when the land would come in for seeding with the Clovers and Saintfoin in admixture. The sixth and last course will be Clover and Grass lea, the latter being broken up in summer and cropped with Turnips, as the preparation for Wheat, as above stated. It will be noticed on this system of cropping that half the arable land will be in cereal crop, two-thirds of which will be Barley, and it must be admitted to be judicious that it is so arranged, for this soil is as well adapted as any we could name for producing a malting quality. The other third is cropped with Wheat, and although under the system adopted only one crop is taken in six years, and although the Wheat grown is generally a full crop, yet it has for some years been exceeded as an acreable money return by the Barley crop. Taking this system as a whole it exhibits great practical knowledge and judicious management, and we can recommend it with great confidence to the careful consideration of the home farmer.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—This has been greatly relieved during the period since harvest by the judicious employment of steam power in the cultivation of land intended for early cereals and root crops next spring. Not only has a vast deal of the heavy work of cultivating been done, but it has been effected within the shortest time that is possible for autumn preparation of the land, and particularly as we never can reckon beyond a certain number of days in the most favourable seasons. We have not only the certainty of the autumn rains commencing during the month of October more or less, but the practical fact that the seed time for the autumn-sown Wheat must during that month receive a large share of attention. By steam power, however, the ploughing and pressing of four or more furrows upon Clover lea ground can be done at one pass of the plough in ridging up the land for Wheat. This circumstance also enables the home farmer to continue the autumn cultivating to a later period, in consequence of the great amount of work in ploughing and pressing

for Wheat after the autumn rains have commenced; in fact, upon any dry soil the weather scarcely ever hinders this work on lea ground, even at the latest period for sowing winter Wheat. The selection of seed Wheat is now, as ever, a matter of primary importance, not only of the varieties to be sown but the quantity of seed per acre. The latter, however, is not so much a vexed question as it was some years ago, as it has now resolved itself into a question dependant upon the time of sowing. The earlier Wheat is sown the less seed may be sown: the state of the land and nature of the soil will have its effect. In ordinary cases the quantity may be said to vary from 2 bushels to 3 bushels of seed per acre, the latter quantity to be used after the middle of November.

The varieties of Wheat raised and cultivated for the purpose of being sold for seed are more numerous, and much more pains and trouble are used in their cultivation and selection than at any previous period; for we have excellent varieties as pedigree corn offered us by Major Hallett, and these are well worth attention, especially as it is now the fashion to drill at 10 or 12 inches between the rows. All the superior selected sorts will bring larger ears, and consequently yield better at a wider distance or fewer plants to the rod. We have also a capital collection of varieties offered by Mr. E. Y. Oakshot, seed merchant of Reading, Berks, and also fine varieties offered by Messrs. Webb. The former of these seedsmen are selling capital samples of their Champion white Wheat, also the long-eared and square-eared rough chaff white Wheat. We have seen this year 14 sacks and upwards of the latter grown upon thin light land; in fact, the home farmer should obtain a catalogue of seed corn from the vendors, and he will soon see from the testimonials the varieties which are most likely to suit the soil he has under his care. Although these well-selected varieties are sold much above the ordinary market price of millers' corn, yet by sowing a sack or a quarter only the increase will put him in possession of a considerable quantity of seed Wheat another year. This has been our practice, and we recommend it. There are various specifics now for cleansing seed Wheat from smut, and also deterring birds and insect enemies from attacking the young plant, worth attention, and should not be omitted in preparing the Wheat for seed.

Hand Labour.—This will now be required in assisting the taking up and storing Potatoes and also Mangold. The Potatoes are more or less tinged with the disease, therefore on taking them up they should be assorted, those affected to be used immediately for feeding milch cows and store pigs. The size just under the best market tubers may be saved for seed; but these and the marketable tubers should be stored away in a heap and covered with straw in readiness to be examined again at the end of four or five weeks, before being finally heaped and covered securely for the winter. Seaweed, border grass, short straw, &c., is best to place next the tubers before being thatched and earthed over. Some farmers advocate the earth being put next the short straw or seaweed and the thatch on the outside of all the materials used for covering the store heaps. In the light work of sorting and moving Potatoes the women ought to take part, for we have always found that willing hands will do more than the men at this kind of labour. The Mangolds should now be taken up and stored daily, for we have always found them keep best in heap when put away as fast as they are taken up. The leaves are a valuable green fodder, and analysis proves them more nutritious than the outside leaves of Cabbages. Shepherds in the northern and midland counties will find the ewes of all the long-woolled tribes offering freely to the rams, and it is well to number and stamp the ewes every week—No. 1 and 2 representing the first and second week—as fast as they are seasoned during first, second, and third week, and so on, in order that at lambing time the animals may be specially cared for and separated for special care in accordance with the time of lambing. The horned Dorset and Somerset ewes are just now ready to lamb, many of them being due in a few days. These will require special attention, as they rear so many twins, some of which are frequently weak whilst young. Dairy cows with young calves should now be bought for yielding a supply of milk in the winter months. Fattening oxen in the boxes and stalls must now live at full head, receiving a liberal allowance of cake, bean meal, &c. These should always be given in the meal state and mixed with cut roots, Cabbage and Carrots being ripe first for use. Fattening pigs should now be pushed on, and the cheapest and most profitable way we have found to be by pulping the roots, and mixing the barley meal, maize meal, &c., with the roots (using no water), Cabbage, Carrots, and Mangolds in succession, gradually reducing the roots and increasing the proportion of meal as the animals approach nearer to maturity.

FORTHCOMING POULTRY SHOWS.

NEVER a week passes without some of our readers and poultry correspondents writing to ask our advice about where they can show their birds to advantage. We are always pleased to explain to novices the special attractions which particular schedules offer for their special favourites. For instance, a breeder of some rather rare variety wishes to know where they can best be introduced to public notice. We at once explain that a schedule must be sought where the residuum for the variety class is necessarily small, and where Malays, Leghorns, Black Hamburgs, Silkies, and other well-cultivated kinds do not all come into it. Such

information is absolutely needed by the uninitiated. More than this it is not our province to give, and we frequently now decline to recommend shows. Where we see specially good arrangements we always commend them, and where carelessness and confusion we always fearlessly expose it. To do more than this is not the work of a newspaper. We will, however, attempt to give a short summary of the schedules of the many forthcoming shows by which exhibitors may be helped in making their selection. We do trust that none will from over-ambitious desire of prizes attempt to show the same birds at even half the places where tempting schedules are put forth. It is most impolitic to wear out the constitutions of good birds with much showing; but worse than this, it is cruel.

From now till Christmas there is at least one large and well-known exhibition fixed for every week. As our pages are preparing for the press well-classified exhibitions are being held at Merthyr-Tydvil and Stratford-on-Avon. We do hope that no other committee will follow the strange arrangement of the latter Show, where all the exhibits had to be delivered by noon on Monday. Some similar arrangement, but not on Monday, was once tried at Oxford, caused much inconvenience and delay to the Judges, and failed. That such a plan should be attempted, not in a central and accessible town, but in an out-of-the-way place on a cross-line of rail, seems to us most unwise. On Saturday in this week and on Monday in next comes off the Burton-on-Trent Show for Pigeons and cage birds, with good classes and eight prizes in each. We pity the Judges! On the 21st and 22nd will take place a splendid show of Pigeons, Bantams, and cage birds in the Southport Pavilion. We say a splendid show without knowing anything about the number of entries in each class, but a show where the classification is so good cannot fail to be fine. So many subvarieties of Pigeons are commonly mixed together in a single class that young fanciers are quite puzzled; but where no less than nine classes are offered for Carriers, the same number for Barbs, nineteen for Owls, ten for Jacobins, three for oriental frilled Pigeons, nine for Tumblers, ten for Dragoons, and thirteen for Antwerps, a beginner may gain more practical Pigeon lore in a day than by much reading. Other shows that are pending will be referred to in a future issue.—C.

THE ROSS POULTRY AND PIGEON SHOW.

THIS Show was held on Tuesday in last week in the Town Hall, a building admirably adapted to the purpose. The exhibition of Pigeons was extremely good, that of poultry by no means such as could have been wished. We think that in the case of poultry the Committee made a mistake in offering four small prizes instead of two of larger amount. The cost of carriage is heavy, and exhibitors like other people must think of £ s. d. Pigeons pack closely, and are light, and so many entries are often found even when the prizes are quite nominal. *Brahmas* had but one entry in each class, *Cochins* a few more; the first Buff hen was a handsome bird and would win in better competition. *Dorking* hens were better than the cocks; we admired the first dark bird, and the second Silver-Grey was large though poor in colour. *Game* were better; the first and second cockerels *Black Reds*; the first pullet of the same variety was a stylish bird; second and third, too, very fair *Brown Reds*. *Spanish* there were none, but a good pair of *Black Minorcas* did duty for them and took second prize. *Hamburgs* were few; the Duke of Sutherland's Silver-pencils were by far the best pair, the cockerel very clear in colour and neat in all points. Fair *Houdans* were first and second in the French class. In the Any other variety classes cocks were conspicuous by their absence, but some good Silver Poland hens won. The chicken classes were much better, and better filled; Mr. Bloodworth's two Buff *Cochin* pullets being beauties. The first *Brown-Red Game* cockerel, too, was a bird worth looking at. *Bantams* seem the special fancy of the district. There were no less than thirty-one *Game Bantams* entered, and some of the winners were very handsome birds, though the failing of the present time seems size; many of the best *Game Bantams* we see as to form are immense, doubtless from having no remote relationship to large *Game* fowls. The *Black Bantams* were of course good at Ross, Mr. Phelps' birds taking first and second; the cock in the second pen was a most diminutive real Bantam, but the beauty of the first cock's tail won the pair their position. The class for *Bantams* of Any other variety brought a beautiful collection. First were *Cookoos*, as perfect in colour as we have ever seen any; second, nice *Black Booted*. There were some fair *Sebrights* in the class, but far too large. Two magnificent *Bronze Turkey* cocks were very even, the first slightly the most massive bird.

Geese were represented by one pair of Grey Chinese, which are certainly a very pretty variety. Why people commonly call them *Spanish* we do not know. *Ducks* were a good class; *Rouens* first and *Aylesburys* second. As usual now a large array of *Pekins* appeared.

PIGEONS made a very different show. There were nearly three hundred birds, and the quality was as good as is seen at any but the very best shows. *Carriers*.—As usual Mr. Baker won first with a *Black*, second with a *Dun*, both very good birds; the form of the

first specially struck us. *Pouters*.—The three first were good birds, the rest not remarkable; the first a Red-pied, very slim in girth and all round a fine bird; second a Blue, third a Black. *Barbs* were one of the most remarkable classes we have ever seen at any of the smaller shows; first a magnificent Yellow, second and fourth fine Blacks, third a good Red. *Tumblers*.—Short-faced.—The winners were chiefly Almonds; first very good in head. *Muffed*.—First a Rose-wing, second a Black Beard, third a Blue. *Long-faced*.—First a good Red Mottle very rich in colour, second a Silver Bald. *English Owls* were a large class. First a Blue, particularly deep and good in colour, and with good head properties too; second a beautiful Silver, third a Blue with a very good frill, a point in which many birds were deficient. *Foreign*.—First, second, and third White, the first winning easily; fourth a Black. *Fantails* were few; the first and second were very fair birds and in fair condition. The Judge did not award more prizes, as the rest were deep in moult. *Jacobins*.—Red or Yellow.—All the winners were Red, the first good all round with a short beak; second good too, but less blooming in condition. In the Any other colour class a beautiful Black was first, failing a little in colour, but perfect in hood; second and third pretty Whites. *Turbit*.—Blue or Silver.—A remarkable class; several birds generally in the prize list had to be content with high commendations. First a Blue very remarkable in head properties, second another Blue good in head and frill, third a fine Silver, fourth a Blue. Any other colour.—First a Red, a grand bird all round; second another very good Red, and third a Black. *Magpies* were a capital and very large class. First a Black, extremely rich in colour and clear cut; second and third good Reds. *Archangels* were a fair class, but in a very poor light. The Judge had to carry them two at a time to the light for comparison. First was very good in both Black and Bronze, and second not far behind. *Trumpeters* were capital. First a Black in good healthy condition, with a most symmetrical rose and splendid foot feathering; second, third, and fourth all mottled, with very little to choose between them, all fine in rose but not equal to the first in foot feather. *Dragoons*.—A class of twenty-two. First a long rich-coloured Blue, the only one in the class with a really good dark eyelash; second a stylish Blue, a smaller type of bird; third a Yellow. *Antwerps*.—Short-faced.—A most superior class, the winners all very fine in head. Long-faced, too, were little behind them, first and second winning easily. Any other variety was a most excellent and interesting class. The Judge awarded an extra fourth prize, and considered many birds worthy of very high commendation. First was a Blue Priest, second a Blondinette, third a Satinette, fourth a Blue Pigmy Pouter, and extra fourth a particularly frilly Red Frillback. A good Blue Swallow, a Fire Pigeon, and a Black Priest all deserved their notices. The day of the Show was unfortunately a damp and dull one, after a drenebing night, and the attendance of visitors was very poor.

The Judges were for poultry, the Rev. Grenville F. Hodgson, and for Pigeons, Mr. O. E. Cresswell. There was a pretty show of cage birds, which Mr. P. R. Spencer of Hereford judged.

VARIETIES.

NEW BOOKS.—We have received the following books from the *Bazaar Office*:—*Notes on Game and Shooting*, by J. J. Manley M.A., an attractive and admirably finished volume of nearly four hundred pages, which pleasantly tells much that is interesting about game furred and feathered, and will be welcomed by sportsmen. The author writes learnedly on his subject, and combines with much technical knowledge an agreeable mode of expression. In addition to the table of contents the book ought to have had an index. *Stock-keeping for Amateurs*, by W. H. Ablett, a neat volume of 186 pages, treats concisely and well on the management and diseases of the various farm animals. *Rabbits for Prizes and Profit*, by Leonard U. Gill, is similar in size and style to the foregoing; it contains illustrations of the different varieties of Rabbits, and gives reliable information relative to their management and diseases. On gardening subjects we have the *Hardy Fruit Book*, by D. T. Fish, who has given a great deal of useful and interesting matter in the 276 pages. *Popular British Fungi*, by James Britten, F.L.S., an excellent little work, both useful and instructive. *Orchids for Amateurs*, by the same author and W. H. Gower, contains descriptions and illustrations of the most popular Orchids, with brief but sound cultural details. *Greenhouse Management*, by W. J. May, refers to the ordinary routine of culture of plants usually grown in greenhouses.

— **THE PRICE OF MILK.**—The wholesale price of milk varies with the season, though the public seldom gain the benefit of a reduction. The farmer usually sells his milk by the "barn gallon," as it is termed—that is, seventeen pints to the gallon, or half a pint over-measure at each imperial gallon. Many of them are not aware that it is illegal to sell by such measures, and we would refer them to the Weights and Measures Act, 1878, 41 and 42 Vict., c. 49, sections 15

and 19. The selling by a barn gallon is, of course, an old custom, in which the extra pint was thrown in—for the same reason that extra lbs. of cheese are thrown in at the cwt., and extra ozs. of butter at the lb.—in order to improve the bargain to the buyer. At first these additions were part of the bargain, but they soon became a custom. Other farmers, again, sell their milk at so much "a dozen"—that is, a dozen quarts; this custom is not illegal, but it is rather clumsy. A few sell by the standard imperial gallon, which we think is the best. Milk is generally cheapest in the months of April, May, and June, when the price the farmer receives, less the carriage, is 1s. 4d. per barn gallon. In the following three months he gets 1s. 5d.; in October and November 1s. 8d.; in the next three months 1s. 9d.; and in March 1s. 8d. These are the actual prices contracted for by one who has been in the trade many years, but they are subject more or less to variation in different cases, in different years, and in different localities. The carriage from the midland counties to London is usually 2d. per barn gallon, the empty cans being returned free of charge.—(From "*Dairy Farming*," by Professor Sheldon, for October.)

— **POTATOES IN AMERICA.**—The Potato crop of the country will, it is believed, reach 125,000,000 bushels this year, valued at 100,000,000 dollars. New York, as usual, leads in the cultivation of this esculent, producing not less than 25,000,000 bushels. Illinois comes next with 12,000,000 bushels, and Iowa next. The six New England States produce about 25,000,000, Maine taking the lead in this direction. Her crop of Potatoes last year was estimated worth 4,100,000 dollars. The Early Rose is now confessedly the popular Potato throughout the country; neither rot nor beetle has impeded its march. Its cultivation began in the eastern and middle States about ten years ago. Another Potato, the Prolific, is also sought for on account of its good flavour and evenness of surface. In the New York market the Mercer and the Peachblow at present dispute the palm with the Early Rose, but the last-named commands the highest average price. The Peachblow seems better adapted to a warm climate than the kinds previously named.—(*Prairie Farmer*.)

— **THE ISLINGTON DAIRY SHOW.**—The show of dairy stock and produce which opens at the Agricultural Hall on the 26th of the present month promises to be one of unusual excellence. The entries are largely in excess of those received for the exhibition of 1879 there being forty-six more cows and forty-one more goats, besides a large increase in the quantity of utensils and produce. In the department for Dutch butter and cheese the entries have been so large that the Committees have decided upon awarding extra prizes, and also to still further subdivide the classes, in order to embrace the various makes that are to be exhibited from Holland.

— **CHESHIRE CHEESE.**—A cheese fair was held at Chester on Saturday, at which from 45 to 50 tons were pitched, mostly of medium quality. The prices for the commoner sorts ranged from 50s. to 60s. per cwt., while medium fetched 70s., and a few prime dairies 74s. The demand was rather slack, and as a consequence prices showed a decline on those quoted at the last fair of from 3s. to 4s. per cwt.

— **AGRICULTURAL PROSPECTS.**—Another spell of excessive rain-fall has brought outdoor operations to a standstill, and in many districts of the midlands the damage done by floods has been very serious. Prior to this latest deluge the land was working exceedingly well, and seldom have the stubbles turned up in better form. Now, however, all the clays are very wet, and preparation for Wheat-sowing must be delayed. Portions of the late harvest still remain to be secured, and must now be considered of very little value. Disease appears to be showing itself amongst Potatoes in Durham to a serious extent. This crop in the later districts is now being secured as fast as weather will permit, and it is everywhere spoken of as an unusually heavy one. Pastures are now very full of grass, and both grazing and dairy stock are doing well. Flocks are not well spoken of by the majority of our correspondents, and there is a great want of confidence amongst purchasers in most of our important English fairs.—(*Mark Lane Express*.)

— **AGRICULTURAL DISASTERS IN KANSAS.**—Under the above heading a daily paper has published the following:—In New Mexico

and Southern Colorado no rain has fallen for thirteen months. River beds that have never run dry before are without moisture for hundreds of miles; the grass has ceased to grow, and nothing but the *Caetus* is to be seen on the plains in the way of vegetation. As a consequence the cattle and sheep, which formerly found a capital living here, are dying by hundreds. Unwilling to risk further loss by waiting for rain, the stockowners have determined to transfer themselves and their stock, numbering 200,000 head of cattle and 250,000 sheep, to a more favourable district. The exodus began last April, when a drove of 8,000 cattle and 12,000 brood mares, belonging to Judge Hilton, the "cattle king" of San Luis Valley, New Mexico, set out for the Black Hills country. They arrived at Fort Fetterman in the beginning of September. Other droves belonging to other owners followed in rapid succession, and it is said that from Powder River in the north, to the Rio Grande in the south, there was for some weeks, an almost continuous line of cattle and sheep.

FOUL BROOD.

AFTER all my experience with foul brood I am still at as great a loss as ever to say what is the cause of it. Like some of your readers I thought it was caused by the introduction of the Ligurians into my apiary, but then I had it previous to that time; and besides, a neighbour had it in his long before we ever heard of a Ligurian bee. I am as convinced as ever that chilled brood is not the cause, but one thing is certain—it can be cured, though only with much trouble. For a number of years I had been experimenting with it by partially cleaning the skeps by washing them in hot water and soft soap, and boiling all the honey before I gave it to the bees, and taking away all the old comb every year, leaving only the new; but with all my care my stock was decreasing every year. I at last resolved that I would adopt similar means to those of the late Mr. Woodbury. I began by burning every piece of old comb and everything not connected with the hives themselves, which consisted of the Woodbury hives and some *Stewartons*.

All those which were empty of bees I boiled in a large copper for three or four minutes—skeps, broods, bars, and everything connected with the hives, taking the precaution to do it in a cold frosty day in winter, so that there could be no chance of any bees coming near me. When the operation was going on a man stood with a fork keeping all down in the water, and it boiling all the time; they were then washed in clean water but not so hot, and at last in cold, and then they were dried thoroughly and kept in a shed in which they had plenty of air by day. Some of the skeps were made with straw sides and tops, as *Woodburys*. Those after being dried I painted over the straw with white lead; and in passing I may remark that the bees do as well in those painted as in the wood or the straw without paint. In case of failure in cleaning the old skeps I obtained some new common straw ones, and put swarms in them the same season, 1878, that I put the swarms into the boiled *Woodburys*, which gave me two chances: if they were not clean by boiling, they might be cleaned by putting them into new straw hives. It was giving me two strings to my bow. When fed they had nothing but pure sugar. All my old honey and combs I had destroyed. When they were examined in the autumn I found the *Woodburys* were all clean except one. Why that one I cannot tell, they were all treated alike in every way. The straw hives we could not be so certain of as we could not see all the cells, but we thought they were clean, and found it to be so this spring when we broke them up after they had swarmed and all the bees driven out. In the beginning of June this year I shook nearly all the bees from the *Woodbury* skep which had the foul brood into a clean *Woodbury*, placing the skep with the foul brood, combs, and bees into a vinery for twenty-one days to hatch out the brood. The skep was lifted out of the vinery every good day, that the bees which could fly might have an airing, and kept in the dark while in the vinery. As soon as they were hatched they were added to the one they were taken from, and all the comb immediately destroyed, and the skep sunk over the head in water.

I confess I was afraid the experiment would be a failure, and that it would not be free from foul brood; but after a careful examination of every comb the other day I am glad to say there is not a single cell of foul brood in my twelve stocks; they are now in as good condition as I ever saw them. That same skep gave me a super of 21 lbs., and has 50 lbs. in the skep still. It will be seen that I followed very nearly the course Mr. *Woodbury* recommended, with the exception of placing the bees in a clean skep for two or three days before they were placed in the skep they were to remain in. Had I failed I would have adopted

that plan before I finally gave it up, as it was a matter of some consideration to burn about twenty otherwise good skeps and start with a new lot, when they, too, might have foul brood.

A neighbour here many years ago cleaned his in the same manner as I have attempted to describe, and was also successful. He has now fifty stocks, and has had a hundred in former years, and all perfectly free from the malady.—ALEX. SHEARER.

ANTI-ROBBING PORCH FOR HIVES.

DURING the last two or three years I have had abundant opportunities of testing the working of a simple arrangement I have often recommended to check or cure robbing—that trouble of early spring and late autumn, or indeed of every season when bees can fly but gather nothing. I have so often proved its thorough efficacy, that I have now begun to adopt it as an integral part of my hives, the draw doors of which it replaces. The usual narrowing of the hive mouth, although very helpful to an attacked colony, is not by any means uniformly sufficient. Robbers that have gained confidence by success present themselves with so much assurance that they often slide past the guards and get into the wider opening lying behind the doors before they are known to be intruders. This happening continually will allow a hive after the narrowing of its mouth, if thinned or intimidated before the siege has been noticed, to still suffer from the attack, which will only more slowly, though quite as surely, work its ruin in spite of the precaution taken. If, however, the mouth be not only narrowed but have the form of a tunnel given to it, the would-be thieves are placed at a tremendous disadvantage; they have to pass guard after guard, and the moment they are challenged by one, others are at hand to close with them to do battle or commence the work of ejection. The combatants fill the aperture in the tube-like opening; and the tussel, which by its excitement gives in ordinary arrangements opportunity to sneaking watchers to slip in, bars effectually all ingress. The defenders gain courage; and the marauders, finding it all fight and no booty, in an hour or two seek some new field for their energies. I now cut two pieces of wood about three-eighths thick, 2 inches wide, and 5 inches long. One of these is nailed to the end of another about 1 foot or 14 inches long, and also 2 inches wide. The unfixed piece, now sliding backwards and forwards under the two, gives the size of the opening to the hive as they stand together on the alighting board. The opening is altered in a moment to suit season and size of stock, and has this great advantage, that when robbing begins and it is needful to make the entrance very narrow, it is still the one known to the proper inhabitants, to whom it in consequence does not add the disadvantage of a bewilderment at the very moment home has to be defended against an enemy. The skep as well as the frame hive may be very easily furnished with this before-described form of entrance, which would certainly reduce the chances of stocks being robbed out to a minimum, while those who know how often the cottager loses his "stances" from this cause will not think any help in this direction to be disregarded. Last year I had an opportunity of saving for a primitive bee-keeper a stock from destruction, before which, he said, "the bees was always a-fightin." I found in the somewhat rugged pathway two pieces of thin tile, one of which I broke in half, and placed the parts in front of the skep mouth with the newly separated edges, about a third of an inch from each other. The other piece, by being put over these, formed the protective tunnel at once.

Uncontrollable robbing, it is true, points to some error in management or defect in condition in the hives themselves, and in the apiaries of uninstructed bee-keepers robbing is sometimes a blessing in disguise, as two stocks, each singly too poorly provisioned to winter, will first fight and then fraternise, and deport the whole of the stores from the hive to be deserted to that of the attacking party; but this, though true, but represents the exception. In all well-cared-for apiaries robbing is not only a nuisance but a loss, for which not one shred of countervailing advantage can be pleaded. The importance of preventing rather than curing robbing is enhanced by its tendency when commenced to rapidly increase until honest labour seems to be forgotten in the hurry to get booty from others. Its annoyance where many bees are kept is felt in the savage ill temper it infuses into all stocks alike. The wasp, which this season has been unusually troublesome, would find the kind of entrance I am now recommending a bar to progress by no means to his liking.—FRANK R. CHESHIRE, *Acton*.

A FIGHT WITH FOUL BROOD.

I AM truly glad to find that our old friend Mr. Pettigrew has given such an emphatic warning of the danger of trifling with

this dread disease. While others are scoffing at it as "imaginary," and doing their best to quiet alarm regarding it, Mr. P., as the result of life-long experience, declares that once it gets a hold it never lets go till destruction ensues. My experience during the past season has been so singular, and I venture to hope so instructive, that I shall break through reserve and tell my tale.

On several previous occasions I have had experience of foul brood, but only in an occasional stock, generally a purchased one, and I had never failed to effect a cure at the expense of the combs and a mere weakening of the stock. A two-days quarantine, a clean hive with comb foundation, and subsequent feeding with salicylic acid in the syrup, had been usually a certain cure. My experience this season seemed to set the results of all previous experience at defiance. Not an isolated stock, but half a dozen at a time, began in early summer to develop traces of foul brood notwithstanding that the acid was being used in the food of all. At first I was alarmed; then I began to doubt if it could be foul brood at all, owing to the fact that the bees were generally clearing out the putrid grubs instead of sealing them over as I had formerly observed. I observed also that many grubs were dying before they were sealed over at all, and others after they had passed into the nymph stage. These appearances led me to think that the trouble was caused by the food, that the grubs were poisoned with salicylic acid. The acid was stopped, but the disease went on. The affected hives were decreasing in strength, and there remained nothing for it but to transfer the swarms after quarantine into clean hives. Suspicion being aroused all other stocks were examined, and most of them exhibited traces of the disease, a few being very bad. All were now treated alike, having a clean shift, and such a melting-up of beautiful combs I never saw. The hives being valuable were used again after a thorough scalding and washing with permanganate of potash.

I now fancied that though I had ruined my prospect for honey I should have no more trouble from disease; but I was grievously mistaken. As the honey season was just fairly in I once more found half a dozen affected stocks. At my wit's end, I resolved to let these take their course till the time for winter packing should arrive, when I might unite the bees of several condemned stocks into one on clean combs. In despair I was almost resolved to apply the brimstone match as a radical cure. All this time I had been keeping a strict look-out among my neighbours' bees, and endeavouring to discover whether any besides my own were affected. Only one did I discover, and it did well after I transferred it. I fancied I knew the condition of every stock within a mile and a half of my own, and this made my case all the more mysterious. I had, however, neglected or forgotten to examine the "laird's" bees about a mile off. Only a few days ago I was reminded of this, when a message reached me from the lady requesting me to examine the bees and see if I could discover why they could get no supers this year. Suspicious of foul brood, I asked for an empty skep into which I might drive the bees of two others to be taken for their honey. The only unused skep on the place was pointed out to me lying on its crown in an open shed, double eked, and full of black ugly comb. On tearing out the latter I was horrified to find it putrid with foul brood. Before waiting an explanation I ordered a grave to be dug into which corruption itself was trampled. The gardener now gave me the history of that skep, and at the same time the solution of my mystery. The stock had dwindled in spring and been robbed out at last. To give free scope to the robbers the skep was set on its crown; a very small remnant of an early swarm had then been introduced among the empty (?) combs. It lived only about five weeks, perishing from foul brood. The limits of the old and new deposits of corruption were very easily observed in the combs. Again the skep with its modicum of fresh honey and renewed putridity was inverted for the benefit of all comers. That my bees had their full share of it was evident from the number of my Ligurians even then working on the Mignonette that grew near the grave where I had just buried as foul a relic of old times as I ever hope to see. I need not say I came away vowing that I would henceforth "heckle" every candidate for Parliament with the query, "Will you vote for a Bill to make the provisions of the Contagious Diseases (Animals) Act applicable to bees as well as sheep, cattle, and swine?"—WILLIAM RAITT, *Blairgowrie*.

OUR LETTER BOX.

Age of Eggs for Sitting (*P. L., York*).—We prefer eggs not older than a fortnight. Eggs much older have produced thrifty chickens, but it is certain, as a general rule, that the older the egg the weaker its progeny. To keep the eggs until you are ready for them put a box in a dry place in your kitchen, not too near the fire; partition the box, so as to hold separately the different eggs of the various sorts; let bran be well dried in the oven and put into the partitions, and cover the eggs with the bran as they are placed in; and this should

be done soon after they are laid. In this manner they will be prolific from a fortnight to three weeks. Always mind to place the thin end of the egg downwards, so as to stand upright. Set your hens in a dry warm place in cold weather, or you will find your mistake out when you look for chickens.

Fattening Fowls (*Housekeeper*).—Oatmeal and barley meal alternately mixed with milk, and occasionally with a little dripping, is good food. The feeding troughs, which must be kept constantly scoured, should be placed before the birds at regular intervals, and when they have eaten sufficient it is better to remove them, placing a little gravel within reach of the coop to assist digestion. Oats and rice are far inferior to oatmeal in their flesh-forming properties. Keeping the birds without food for some hours after they are put up frequently induces them to take it more readily afterwards, but sufficient attention is rarely bestowed on the various details of preparation and supplying the food; hence complaints of the fowls deteriorating in the fattening pen are far from uncommon. Access to water should be allowed at all times. Fattening must be completed in from ten to twenty days, for after that period they begin to lose weight.

Scurf on Head of Cockerel (*W. J. B.*).—Rub the scurfy part with compound sulphur ointment. You will also do well, while this appearance keeps on, to give occasional doses of castor oil—a tablespoonful twice per week. Lettuces are also beneficial, especially those going to seed. Be careful not to injure the blood feathers. The injection of a little hot water will cleanse the ears; you may use a syringe for the operation. Your other birds are suffering from cold. It is enraging; the administration of some bread and ale twice per day, and allowing them to drink very little, having no water by them, but only being allowed to sip morning and evening.

Acorns for Cows (*A. R.*).—Acorns will answer for dairy cows, but they answer better for horses, young cattle, breeding sows, and store pigs, because they contain principally flesh-forming and heat-producing properties. They should, however, if given to dairy cows be either cracked or bruised by the root-pulper, as in that case they will be the more easily digested; horses and pigs can masticate them uncrushed. We do not like to venture to give dairy cows more than a quart of acorns at one time, and not oftener than twice a day, but always in admixture (after being crushed) with roots, meal, or chaff. They will also prove a good mixture with linseed cake or cotton cake properly mixed.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

- 3rd.—Very fine, bright, cold day; starlight evening.
4th.—Misty dull morning, rain from noon.
5th.—Excessively warm damp morning, stormy with heavy rain during the day.
6th.—Overcast showery day; heavy rain for short time in evening.
7th.—Dull all the forenoon; very fine with sunshine in afternoon; bright lightning from 10.30 P.M. till 5 A.M. (8th), with thunder at 4.30 A.M.
8th.—Rain in forenoon; fine pleasant afternoon and evening; rain after 9 P.M.
9th.—Wet day throughout; high wind with heavier rain in evening.
Considerably colder, with frequent heavy rain.—G. J. SYMONS.

COVENT GARDEN MARKET.—OCTOBER 13.

No alteration this week. Market quiet. Prices remain the same.

KEEPING GRAPES.

YOU would find out your mistake if you tried that plan at our place," said a good old-fashioned gardener of more than average experience, on seeing some labourers deluging the inside borders of a house containing Grapes which had finished colouring, and this, too, on an autumn day, which could not be considered a fine one. When the visitor was assured that such work was commonly done on days which were too wet for outside work to be proceeded with his surprise was evidently great, and he made up his mind that Grape-growing was an easy matter excepting in the one locality where he had the misfortune to reside. In the Grape-room, where there was nothing but the natural soil for a floor, the same idea was uppermost. "How could it be possible to prevent the moisture rising and settling on the fruit?" And, again when a house containing ripe Grapes has to be filled with bedding plants, how is the decay of the fruit to be prevented?

It may be useful at the present time to enlarge a little on this subject, as cutting and preserving Grapes by inserting in water a portion of the stem on which the bunch is grown has become almost a general practice, and I think there is a tendency to resort to it unnecessarily early. There are great advantages, of course, in clearing a house of Grapes as soon as they are ripe. The fruit can be kept in a smaller space, and the house can be used for another purpose; but the principal advantage in my opinion is, that the Vines can be pruned as soon as the leaves have ripened, and the process of exhaustion attending the carrying of a crop of fruit, as well as the subsequent bleeding resulting from late pruning, is prevented. The latter advantages, which I put as the principal, can be attained by cutting the Grapes in December, and this I contend for all Vines which are not to be forced is sufficiently early, while for late thick-skinned Grapes, which are to be kept till April or May, the first week in the new year is soon enough. If the fruit is severed from the Vines while there is still a vigorous circulation going on the change is too great, and the fruit will not keep so well as if it had been allowed to hang till some of the foliage had ripened and fallen. As for a dry atmosphere being necessary for keeping or ripening fruit, I thought that idea had been long ago exploded; but old notions die hard, and it may be that others besides my visitor still adhere to it. There would, I imagine, be no insurmountable difficulty in keeping Grapes over the full tank in the Victoria Regia house at Kew, provided I had the control of the heating and ventilating.

The keeping of Grapes in the manner indicated is simplicity

itself when understood. Never allow a very low temperature; and when a high one is unavoidable, give all the ventilation possible before the rise takes place, and condensation, which is the chief cause of damping with fruit, flowers, and plants, will be prevented. It may be said that the more moisture the more danger there is. Perhaps so, but I have never seen a room so dry that condensation would not take place sufficiently to cause injury if you allowed the temperature to rise 10° or 15° very quickly, and I question if a moderately moist atmosphere which is not stagnant is not quite as good for keeping fruit as a dry one. If a fixed temperature anywhere between 35° and 45° could be maintained with a buoyant atmosphere, I imagine nobody would have any difficulty in keeping Grapes; but in the western counties especially we are subjected to great and rapid fluctuations during autumn, and it takes a considerable amount of skill and practical experience to be able to guard against any evil effects from them.

It may be of use to some of your readers if I tell them that it is immaterial which end of the Vine shoot is inserted in the water. Sometimes a bunch is produced so close to the main rod that sufficient stem cannot be cut behind it to allow of its being inserted in the water. When this happens there is always sufficient length of wood beyond the bunch for this purpose, and it will make no difference to the keeping of the Grapes if the wood is placed upside down. I had at least a dozen bunches of Alicante inserted in this way last winter, some of which were the very last to be used, and that was on the 12th of May. I was led to try this plan on hearing that my friend Mr. Wildsmith, at Heckfield, had caused one of his Vines to grow the reverse way by pegging the top down, and when rooted to cut off its end which had the original roots.—
WILLIAM TAYLOR.

COCOA-NUT FIBRE REFUSE.

SINCE old Donald Beaton first made the value of this substance known to horticulturists through the columns of the *Cottage Gardener* many years ago, hundreds of cultivators have proved its worth in various ways. Much was published relative to its merits some twenty years since, but latterly little reference has been made to it in the horticultural press, consequently there are many amateurs and others who are not now well acquainted with the uses of this material. To such an extent is this the case, that a firm which manufactures this refuse largely—Messrs. Chubb, Round, & Co., of Millwall, and who advertise it in the columns of the *Journal*—have received so many inquiries that they have found it necessary to adopt special measures for giving information on the subject. A gardening journal, however, is appropriate for circulating information of this nature, and especially the *Journal* which was the means of introducing the material to the horticultural public.

Now that bulbs are being potted and plunged to induce root-action, it will not be inopportune to direct attention to this valuable garden requisite. For amateurs generally, and those who have gardens in the vicinity of towns particularly, this article is indispensable. It is the best of all substitutes for leaf soil for mixing in composts for potting where a light ingredient is required; as a medium for plunging potted plants in it has no equal; and for propagating purposes it is employed largely and with the best possible results. Most of the Hyacinths, Tulips, &c., that secure the prizes at the principal

London shows pass their first stage under a thick covering of this material, which is preferred to ashes or any other medium. It harbours neither worms nor grubs, retains a uniform moisture, is clean, light, and altogether beneficial, and, further, being so extremely cheap it is surprising that a supply of it is not provided in all gardens. Yet this is by no means the case. It is cheap enough for incorporating with the strong soils of gardens, and rendering them not only more easily workable but more fertile; indeed it was the striking results of its use in this respect that induced Mr. Beaton to test its value for plants in pots, the results of which he communicated to your columns for the benefit of the public. The soil of the then Experimental Garden at Surbiton was so strong, unfertile, and difficult to manage, that it occurred to the clever manager and quick-witted observer, that a few loads of the huge pile of vegetable refuse that inconvenienced the owners of a cocoa-nut matting manufactory at Kingston would improve the staple of his garden. He was readily given as much as he liked to cart away, and as he did nothing by halves he spread it on the ground a foot thick or more and forked it in. The effect was astonishing; the flowers and vegetables that before could only be grown with difficulty now grew luxuriantly, and the value of the refuse was established.

Mr. Beaton has written, "My own garden, which was a poor black sand, is now one of the most fertile in Surrey by mixing two parts of the stuff to one part of the black sand to the depth of 18 inches; but I have it mixed twice that depth. Use it like leaf mould, or in lieu of peat; mulch and mix with it all kinds of soils. Even clay can be made into potting loam by mixing twice its bulk of the refuse with it in two seasons. When mixed spread out as thin as possible to get it well frosted and sunned, and when it is quite dry in July or August run a roller over it, and then give it another frosting and summering, and it will be ready for use. This fibre is free from any acid, saline, or tannin principle. Worms do not like it, and snails and slugs cannot well crawl over it, as it sticks to them, the surface of it being as dry as powder when the weather is anyways dry. It is the best mulching stuff, and 2 inches thick of it on a Vine border would keep the surface of the border as moist as need be a whole season, with no danger about keeping the air or the heat of the sun from the soil. Every plant, bush, and tree over the roots of which a few inches of it are placed, will root up into it in one season, and every root will 'fox-tail' in it, as being so very porous, so retentive of moisture, and so free from taste, smell, and qualities which roots dislike, they run freely in it and feed abundantly on the moisture it holds. The more recent or fresh it is the longer it will last, and the better it is for all the purposes for which it is used."

For Ferns, Camellias, and Orange trees it has been found valuable; it is best and neatest of all mulchings for flower beds in summer, and it is useful for placing over the roots of tender plants in winter, also for surfacing the beds of Pinks, Pansies, and bulbs; in fact, its uses are manifold, and a supply ought to be at the command of every gardener.—A NURSERYMAN.

[We have received samples of the cocoa-nut fibre refuse from those who advertise it in our columns, and in each case the substance is of excellent quality. We have used it for various purposes with the best results.—EDS.]

THE STAPLEFORD ROSES.

As the merits of these Roses seem to be up for discussion, it would be interesting to many if one or two of our amateur Rose-growing friends would favour us with their experience.

One of our leading nurserymen (Mr. B. Cant), whose knowledge of what a Rose is and should be I think none will dispute, says in his catalogue, page 13—"Bennett's new hybrid Tea Roses have with me turned out perfectly worthless. It will be as well to give them a trial another year before throwing all of them away, which I anticipate will be their ultimate fate."

At the dinner upon the occasion of the Rose Show at the Crystal Palace we had as guests two eminent nurserymen and Rose-growers from the United States. They were very decided in their opinion as to the unsuitability of these Roses for outdoor culture, but spoke well of them for forcing.

If the constitution of Mr. Bennett's Roses is such that they will not open in our moist climate, and are only suitable for pot

culture, our best thanks are due to our worthy friend "D., Deal," for his seasonable remarks, which will have prevented many from ordering, thereby saving much disappointment next season.—M., Chester.

LIFTING UNRIPE POTATOES.

To the accusation of "A. K. B." on page 351, that he has been misled by any statement of mine, I emphatically plead not guilty. Never has any article been written by me "advising the lifting of all Potatoes when still in a growing state," but for many years I have repeatedly urged upon your readers to lift the Potatoes *as soon as growth ceases*, and before the disease has touched them. Not only have I so taught but so acted, not with invariable success, for, as has so frequently been explained, nothing can save Potatoes from disease in a wet summer; but given a few fine days at that critical time when growth has ceased and the ripening process begun, and the tubers are lifted, housed, and invariably saved. But mark this, they are never put in the store sheds and left for long; on the contrary, they are examined frequently for about six weeks afterwards, and the discovery of a single diseased tuber is the signal for an immediate and thorough overhauling of the whole of them. For the closest observer may overlook traces of incipient disease at the time of lifting; a single shower while we are asleep may have brought it, and then it is only by the exercise of great watchfulness and care that the crop can be saved.

This year, as was stated, the entire crop was lifted and placed in the store sheds early in August. Since then the whole of the tubers, nearly 200 bushels, have been handled and closely examined five times. They are now perfectly dry and sound, well repaying the pains and care bestowed upon them after the lifting. Had "A. K. B." so acted, he would have had no "tale of horror" to tell. Again I say to all, Lift early, store thinly, keep your eyes open and your wits about, and do not hastily condemn a well-tried plan simply because you do not understand it.—EDWARD LUCKHURST.

THE failure of "A. K. B." detailed on page 351 has, I am convinced, arisen from some error in management, and is not the fault of the system that has been practised successfully by Mr. Luckhurst and other cultivators for many years. I am not aware that anyone has advocated the lifting of "all" Potatoes when still in a "growing state." What has been advised and adopted with uniformly satisfactory results, is the lifting of the crop immediately the tubers have attained their full size, not waiting for the haulm to decay. For more than twenty years I have taken up my crops of early Potatoes as soon as the tubers attained their full size, whether the haulm was green or not, and not in one instance has anything like such a disastrous result followed as that recorded by your correspondent. There is a difference between the haulm being "green" and the crop "still growing." There is a cessation of growth where the tubers have attained their full size; and if, as is nearly always the case with the early varieties, this occurs before the disease sets in, the taking-up of the crop, or the pulling-up of the haulm, leaves the produce sound. If the fungus has attacked the foliage before the removal of the haulm or the digging of the crop, then the early digging or haulm-removal goes for nothing, and the lifted produce will decay. I have never been able in this cold northern district to save the late crops, such as Paterson's Victoria and York Regents, by the practice in question, simply because the tubers have not attained their full size before the disease has set in; but in the district in which Mr. Luckhurst labours the crops are earlier, and he succeeds in saving late as well as early varieties. As proof of the safety of the practice advocated by Mr. Luckhurst when rightly carried out, I am intimately acquainted with a cultivator who has adopted it for forty years without failure, and his stock of Early Ashleaf so long preserved is as productive as ever.—A NORTHERN GARDENER.

INJURY TO WELLINGTONIA GIGANTEA.—Mr. Geo. Parkin writes as follows in the "Journal of Forestry":—"This magnificent tree seems to have fallen in for a full share of the injury which has been inflicted this summer upon almost all kinds of trees, whether deciduous, evergreen, or Conifers, by the different insect tribes. There are a few fine specimens of the Wellingtonia gigantea on the Wortley estate, the seat of the Earl of Wharnccliffe, varying in height from 5 feet to 30 feet, the lesser portion of which are still in the nursery grounds. About the beginning of last month my attention was attracted by the appearance of the tips of the branches, which, as well as the leading shoots, were drooping and turning brown. On carefully examining the trees I found them infested with a kind of spider, rather transparent,

and which, in my opinion, is the cause of the disease, each family being carefully protected from the wet and cold by a well woven covering of insect wings and bodies, small leaves, &c., about the size of a lady's thimble. These coverings varied in number from two to six on each tree; some of them enclosed a greenish-looking egg, in the centre at the top, the old spider sitting underneath it, no doubt in the act of incubation. Some of the habitations or coverings are attached to the stems, others hanging underneath the branches, which were each occupied by a family of young ones, varying in number from six to twelve, as far as I could ascertain, about the size of a small shot corn, each tent being well protected from their stronger enemies by massive webs. My first object was to cut off the branches most affected, and destroy as much as possible the holds of the invaders. I have since applied three or four solutions of paraffin and water, but with little effect. I am now trying a similar solution of soft soap, and sprinkling the ground with lime, which I hope may have the desired effect. *Pinus nobilis*, *Nordmanniana*, and *austriaca* have all slightly suffered from the same cause. The pest, I fear, is general, as I have seen it in the neighbouring woods and nurseries."

PLANTING APPLE AND PEAR TREES.

AS the season will soon be at hand for planting fruit trees I think a few remarks will not be inopportune to amateur planters. To commence with: Most people prefer size, quality, and quantity of fruits, and to obtain such you must have good trees, to be afterwards well attended to as regards dressing and pruning.

I think it is a mistake to plant Apples on the Crab stock in a kitchen garden, as they grow too freely and require too much pruning. For orchard planting Apples on the Crab are preferable, as they grow freely and only require the branches to be thinned out, cutting out those that are inclined to cross others. For kitchen-garden planting Apples on the Paradise stock are the best either for pyramids or espaliers. They come into bearing much sooner than those on the Crab, besides bearing much finer fruit. The same may be said of the Pear, those on the Quince being much finer and come into bearing quicker than those on the Pear or free stock. Trees that have the soil dug amongst them produce better fruit than those with the soil left undisturbed. After planting, which should be just as the leaves are falling, mulch with long litter. The first year after planting they will require very little pruning; the following season treat as established trees. The lateral growths should be pruned-in about the last week in August, which will expose the fruit to the sun and air, besides ripening the buds for the following season. At the winter pruning the shoots may be cut in close to the fruit buds. If large fruits are required they must be thinned.

The best Apples to grow for certainty of crop are, for culinary purposes, Ecklinville Seedling, Lord Suffield, Stirling Castle, Alfriston, Lord Derby, Emperor Alexander, Mère de Ménage, Waltham Abbey Seedling, Warner's King, Cellini, Dumelow's Seedling, Gloria Mundi, and Loddington Seedling. The above almost always produce a crop. For dessert the following are good—Ribston Pippin, Ashmead's Kernel, Adams' Pearmain, Old Nonpareil, Braddick's Nonpareil, King of the Pippins, Golden Reinette, Worcester Pearmain, Cornish Gilliflower, Court Pendu Plat, Melon Apple, Cox's Orange Pippin, and Royal Russet. The above are a good selection, and if on the Paradise stock will take up very little room and commence bearing the second year after planting. Pears succeed best planted against walls, but good fruit may be procured from pyramids grafted on the Quince. They require about the same treatment as Apples. The best varieties for succession are Doyenné d'Été, Beurré d'Amanlis, Flemish Beauty, Beurré Hardy, Beurré Superfin, Marie Louise, Beurré Diel, Doyenné du Comice, Gansel's Bergamot, Durondeau, Josephine de Malines, Thompson's, Glou Moreau, Winter Nelis, and Knight's Monarch.—FRUIT GROWER.

VALORADIA PLUMBAGINOIDES.

THIS charming little plant is better known under the name of *Plumbago Larpentæ*, but the above is accepted as the correct title by the best authorities, as there is some trifling difference between the genera *Plumbago* and *Valoradia*, though to a casual observer they appear very similar. Its chief recommendations are the brilliant blue colour of the flowers and the late period at which they are produced, the plant in the south of England often being very attractive until near the end of the present month. Unfortunately, however, in the northern parts of the kingdom the frost often destroys it, especially in exposed positions; but in such localities it should be grown in pots, succeeding well in a cold frame or cool house. Whether planted out or grown in pots a rich loamy soil is required to obtain it in the best condition.

Valoradia plumbaginoides has been in this country upwards of thirty years, and the following remarks from the pen of an able writer, which appeared in the first volume of the *Cottage Gardener* a short time after the plant was introduced—namely, in 1848, may be interesting. Under the heading "New Plants" he wrote thus:—"The charms of novelty are nowhere more irresistible than in the garden, and this often leads to some blunders. You hear or read of such-and-such fine plants 'coming out,' as the phrase goes, and your very fingers itch to possess them; but after laying out a handsome sum to procure them you soon find that they are no better than they should be. I shall pledge my word, however, that no one who will buy the plant that I shall name to-day will ever feel a disappointment respecting it. It is from the island of Chusan, on the coast of China, and is called *Plumbago Larpentæ*. *Plumbago* means Leadwort. The second is a complimentary name to Lady Larpen, who was so lucky as to

Fig. 68.—*Valoradia plumbaginoides*.

raise this plant first from seed sent to her ladyship by a British officer. This new Leadwort, then, is a charming, low, bushy, blue-flowering pot plant that will flower as easily as a *Fuchsia* from June till the frost comes, and in less than two years will be in every cottage garden in the kingdom. Although it was sold last August as high as 45s. each plant it may be had now for 3s. 6d., and before the end of next May I should not wonder to see them advertised at 9s. the long dozen, and all this because it comes from cuttings as easily as the new *Verbenas*."

The prediction concerning the price has been verified, for good roots can be obtained for 9d. each, and the stock is readily increased by cuttings. The flowers are slightly fugacious, but they are produced very abundantly in favourable positions, the brilliant blue colour gradually becoming a deep violet as the flowers grow older. The annexed engraving fairly represents the characters of foliage and flowers, but the plant is slightly straggling in its growth, except when very luxuriant.—L. C.

THE GRAPE TOMATO.—On one of the side shelves in the temperate house at Kew may now be seen some fine examples of the Grape Tomato. The plants are nearly 2 feet high and about 1½ foot through, trained round three or four stakes. There are several bunches of fruit on each plant, the individual berries

being about the size of a sparrow's egg and bright red in colour. Employed as they are at Kew, dotted between the other foliage plants, it is really surprising what a cheerful appearance they have. That was the first time I had seen them grown in pots, and under more liberal treatment it would make a plant worthy a place in a conservatory. Intermixed with foliage and flowering plants it would have a very pretty effect.—VISITOR.

GLADIOLUS DISEASE.

"R. P. B.," on page 323, has struck what I hope is but a keynote to an interesting overture. I with him await with interest the contribution of "D., Deal," with regard to this year's experience. I have now successfully cultivated these, the grandest of all our autumn flowers, for several years. This I may say, after the testimony expressed in the presence of our friend "D., Deal," at Helensburgh, and the fact that an extra prize was awarded me last month at the Show of the Royal Caledonian Horticultural Society in Edinburgh. What is the sequel? I have drawn out of the ground and burnt the corms that produced the spikes so much admired in the Waverley market. Among these was *De Mirbel* which never failed me before. This I flowered literally from bottom to top, and those who grow the variety will know what nineteen open flowers of *De Mirbel* mean. Then followed, I mean to the waste heap and cremation, *Adolphe Brongniart*, *Andromeda*, *Brennus*, *Carnation*, *Daubenton*, *Lady Bridport*, *Le Phare*, *Pictus*, *Psyche*, and others. Now comes the difficulty. I once wrote to our Journal on the same subject, and specified *Madame Desportes*, *Meyerbeer*, and *Ondine* as the varieties that failed regularly with me and my neighbour amateurs. Well, one out of three corms of *Madame Desportes* has gone, and not one of the others I have mentioned as bad keepers, and which I made up my mind to purchase every spring.—A NORTHERN AMATEUR.

PLANTING POTATOES IN THE AUTUMN.

I HAVE been preparing some ground to-day, more by way of experiment than otherwise, for early Potatoes, and wish to draw the attention of the readers of the Journal to a subject of importance, with the hope that those who habitually plant at this time of the year may be induced to give us their experience. A few words on each of the following heads would be useful—the soil, sets, manure, and preservation against frost. The main point to be kept in view is the latter, and this must be borne in mind when considering all the rest. The soil cannot be too friable from this standpoint, as frost cannot enter so easily nor moisture be retained as if not possessing that characteristic; and the non-retention of moisture means that the sets are less liable to decay and the soil less liable to be congealed. I am using a prepared space by a warm south wall. The sets have been thoroughly ripened and greened; and though I have had the large tubers cut and cauterised with slaked lime, I prefer for this planting to use whole small tubers, as being healthier and less liable to decay in a wet season. At present I am trying *Ashleaf Kidney*, *Early Rose*, and *Bresee's Peerless*, still keeping in view their preservation in early spring. I am using old hotbed manure exposed some time and now rather dry. In any soil with this no moisture can lodge. I do not agree with those who recommend no manure for autumn Potatoes. As a precautionary measure it is generally recommended to put the sets 2 inches deeper than usual.—W. J. M., *Clonmel*.

WILL you kindly answer the following questions through the *Journal of Horticulture*? My master went out last week and saw the best (as he said) horticulturist in England, who told him to plant Potatoes in October, as they are much better than those planted in spring. The gentleman told him the system was quite a new one. I ventured to say it was not new, as I feel sure I read of it in the Journal a long time back. Can you tell me the numbers it is in, how old the practice is, and where it originated? Our Potatoes are to be planted at once.—WIMBLEDON.

[This "new" mode of planting Potatoes in the autumn is in reality a very old one. So far as we know the first person who publicly advocated autumn planting was Mr. James Tindall, gardener to J. Errington, Esq., of Beaufort House, Durham. He has stated that he adopted the practice in 1820, and published his recommendation in the "Transactions of the Horticultural Society of Durham." In the very first number of the *Cottage Gardener* the system is referred to approvingly, and in the first half-yearly volume more is published relative to the practice than probably in any other work. In the years 1844, 1845, and 1846 the practice was adopted by many cultivators, and often very suc-

cessfully. For instance, Mr. Barnes of Bicton, who was known as one of the most practical gardeners of the day, wrote as follows in 1846:—"We have had astonishing crops of Potatoes this season from the autumn-planted, and what we have left in store keep very well in charred matters. Our seed tubers, too, at present are sound and good, having no appearance of disease; but then they have been well dressed with soot and charred sawdust, with a small portion of slacked lime added, and well greened. I am quite satisfied with them at present. Though our autumn-planted crops are so abundant, we have none worth digging or taking up from those planted in spring."

Yet notwithstanding much evidence that was published in favour of the practice the system never became general, possibly because it was not always correctly carried out, that it did not succeed equally well under all seasons, or it was not well adapted for all soils and districts. It is certain that the plan never became common in the large Potato-growing districts of Lincolnshire and Yorkshire, nor was it practised or advocated by such experienced cultivators as Mr. Fenn or the late Mr. R. Fish; nor is it adopted now by such gardeners as Mr. Abbey, Mr. Luckhurst, and others; indeed, the great majority of gardeners find it advantageous to store and prepare the seed intelligently and plant in spring. This also is, we think, the practice of the Potato fanciers whose object is to grow the best produce for exhibition. Potatoes that have been planted in autumn in some strong soils have not come up regularly on account of the soil settling so close and firmly round the tubers by the winter's rains, and then being "baked" by the sun in early spring. The land also, under field culture at any rate, could not be so well cleaned when planted in autumn, and weeds often gained the ascendancy. In your district the soil is light, and autumn planting will probably succeed. Try it and let us know the result. The tubers should be covered 6 inches deep, and they will be safe from frost; in colder localities they should be planted a little deeper. We will readily publish the experience of those who have proved the advantages or disadvantages of this very old system of culture.]

EVERLASTING PEAS.

THE Everlasting Peas seem to me neglected. They may be made to do good service in many aspects. Perhaps their best position is a back row in large borders and open spaces in the shrubbery, and covering old stumps. They are fine on lawns, and for trelliswork and rockery. We do sometimes see *Lathyrus latifolius* and *L. latifolius albus*, *L. splendens*, *L. tuberosus*, *L. grandiflorus*, *L. mutabilis*, and *L. maritimus*; but others, such as *Lathyrus rotundifolius*, one of the most beautiful of the race, ought to be in every herbaceous border, but is seldom seen. It grows to the height of 6 feet in good loam, and is covered with a profusion of beautiful reddish-crimson flowers for a long time in the summer. *Lathyrus magellanicus* is very beautiful. I do not mean what many know as Lord Anson's blue Pea. There appears to be some confusion between this and *L. magellanicus*, which is from Cape Horn introduced many years ago, a bluish-purple Everlasting Pea. I am afraid this will be very bad to meet with; I have not seen it for a long time. Can any of the readers of our Journal tell us where it can be obtained? Such a plant ought not to remain neglected. There are others that might be named, but the above will suffice; they are useful where cut flowers are in demand. Good sandy loam will meet their requirements. They cannot endure stagnant moisture, though bearing drought well. They may be increased by division, but are more readily increased by seed sown either in pots or borders in the spring.—LATHYRUS.

FUNGI A CAUSE OF DISEASE.

WE appear to make but little progress in our discussion of this subject, for Mr. Luckhurst seems solely occupied with the object of endeavouring to support the opinions he has so often expressed in the pages of the Journal; and I cannot help thinking that if he were not quite so positive in his assertions, and manifested more desire to discover the correct view of the matter, it would give more chance of our arriving at an understanding. I accept the explanation that his remarks only apply to the three instances we have discussed, but I am not the only individual who placed a wider signification upon his first statement; and if it was originally intended to apply only to the Potato disease, Peach blister, and the shanking of Grapes, the expression "every instance" was misleading. He also could not have read my last communication very carefully, or he would have seen that I did not imply in any way that he was alone in his opinion, for my remarks applied to the shanking of Grapes, the fungoid cause of which has been advanced by Mr. Harrison Weir and only by him as far as I know

and therefore it could not be taken as a general opinion. As for my not having given any reason for the fungus causing discoloration of the foliage, Mr. Luckhurst appears to be troubled with a peculiarly short memory. He should read my observations on page 280 again; and for their worthlessness, let me tell him that he is totally incapable of disproving that the mycelium does act in a poisonous manner, producing discoloration of the tissues. His long and close observation about "legitimate growth" and "legitimate functions" having ceased before the disease attacks the plants will not establish his case, for I and others have repeatedly observed instances to the contrary. So the question requires no further answer than that his experience is not in accordance with mine.

After twice requesting an explanation of the peculiar circumstance that the *Peronospora infestans* suddenly appeared in this country in 1845 accompanied by the Potato disease, Mr. Luckhurst, who was evidently not prepared to answer it directly, replies in a truly Hibernian manner by asking another question, "Will 'S.' kindly give his authority for the statement that *Peronospora infestans* was unknown in this country before 1845?" My authority is the Rev. M. J. Berkeley, a scientific gentleman of high repute, who was among the first who investigated the cause of the Potato disease, and who has probably spent more years in the study of the lower orders of the vegetable kingdom than Mr. Luckhurst has weeks. He has stated it in several places, but one perhaps that will be conveniently consulted by your correspondent is the "Treasury of Botany," page 923, 1876.

Turning to the Peach blister I observe a strange inconsistency in Mr. Luckhurst's statements. On page 362 he said, "Plant two Peach trees of the same variety side by side, screen one from the wind, but let it be fully open to the air, and there will be no blister," and he further says that the unprotected tree "will be blistered precisely in proportion to the degree of exposure;" but on page 346 he is afraid I am not a close observer, or I should be aware "how worthless are all ordinary forms of shelter," of which I am certainly not aware, for it is directly contrary to everyday experience, and in the instance which I cited the protection from winds was as efficient as could possibly be afforded outside, yet the blister was as bad as it could be. Having first positively asserted that wherever the wind can affect the trees it produces blister, he infers that wherever blister is seen the wind has produced it—a very original mode of argument, but by no means satisfactory, as if he could prove the first assertion the other would not necessarily be correct. As to the plants being free from blister in the houses, I may say that though an instance to the contrary has not come under my own observation, yet an intelligent gardener friend of mine who has had long and varied experience assures me that he has several times seen it occur in houses. I entertain no doubt respecting the actual cause of the blister, but the conditions particularly favouring its production are not so clear. I believe that a thorough ripening of the wood is one of the best means of preventing it, and if that be the case immaturity of the growth or looseness of the tissue would seem to be one of its requirements. Mr. Luckhurst has not yet given us an example of anything similar to blistering being produced in other trees or plants by the cold winds alone.

The following is a brief summary of my reasons for believing that fungi cause the Potato disease and Peach blister. With regard to the first, the disease is invariably accompanied by the fungus *Peronospora infestans*, its mycelium or spores being found in every portion of the Potato haulm or tuber that presents the ordinary appearances of the disease. It is known beyond all dispute that the fungus is capable of producing the rapid decay which takes place in the haulm. It only appears under certain conditions of temperature and moisture. And lastly, both the disease and the fungus were unknown in this country before 1845, though the Potato had been in cultivation for above a hundred years before, and since we have never been free from it. I consider the Peach blister to be caused by the fungus *Ascomyces deformans*, because it is perfectly adequate to the effects. It always accompanies the blister, and is not found upon Peach trees at any other time, and I cannot conceive how the blistering of the foliage could be produced by any but internal injury. The condition suitable for this fungus is, however, as I have already stated, not quite clear, but I think it will be found that much depends upon the ripeness or immaturity of the wood.—S.

DURING the last few weeks the issues of the *Journal of Horticulture* have contained communications from various correspondents, who have ably championed, or assailed, as the case might be, the claims of fungi to the honour (?) of producing disease in plants. On the one side their ideas have been expressed by a full and lucid explanation of the conditions under which the texture

of the Potato foliage, and also that of the Peach becomes injured, or it may be said diseased, from climatic causes, such as cold or wet; and it is asserted that this ruptured state of the tissues of the leaf is the cause of Potato disease, Peach blister, &c. While on the other hand equally good reason is shown, supported by strong facts, that fungi cause disease in these cases.

Microscopic research has been said to prove that when subjected to excessive wet the cells of the Potato foliage become ruptured. The microscope has also shown the mycelium of the *Peronospora infestans* present as soon as disease appears on the Potato leaf.

Now it may be presumptuous in me to venture upon giving my ideas when the subject has been ably handled by writers of acknowledged talent in those matters, but I cannot help venturing the opinion that, if we accept as facts that the foliage of the Potato and Peach become vulnerable from one cause and is then attacked by fungus, we have two concurrent circumstances as causes producing an effect which we call Potato disease. From this I would deduce that it is illogical to call one the effect of the other.—R. CROSSLING, *Castle Gardens, St. Fagans*.

OLD CUCUMBER PLANTS.

THE remarks on the above subject by "A KITCHEN GARDENER," on page 325, were read with great interest by many gardeners, and in continuation I wish to give a few of my observations. If you can keep the old stems in good condition they will produce fruit for a whole year; but whether it is profitable to do so is another question. The grand secret of successful Cucumber-growing is cleanliness, for unless the foliage be clean no very satisfactory results can be expected. This year plants put-in in January are now in full bearing, and I have cut since March 1700 fine Cucumbers. I have examined the plants to-day and find them likely to last as long as I wish to keep them—namely, until Christmas, when my early plants will be in a bearing state. To keep Cucumbers in good condition they must never be neglected in the supply of water at the roots, and also they must be thoroughly syringed at least once a day with tepid water. I place the water cans on the pipes, and find the water sufficiently warm either for supplying to the roots in the morning or syringing in the afternoon. The house is 80 feet long, a lean-to, though tanks take up 4 feet at each end of the bed. Frequent top-dressing is attended to, and I prefer giving a little at a time to a great depth at once. I plant 3 feet apart and encourage the production of foliage and wood from the base of the plant, as it helps to thicken the stems. I have only lost one plant, and this damped off at the collar. To maintain a regular supply of Cucumbers the treatment should be regular as regards temperature, ventilation, tying, and stopping. I examine my plants once, sometimes twice or three times a week; by so doing I have a constant supply of young wood to take the place of the old leaves. I have grown several varieties here, but none have equalled the Telegraph, especially in the early part of the year. I noticed this spring that I cut from plants of Telegraph three times the quantity of good fruits that I obtained from the same number of plants of any other variety. It is advantageous to afford a little shade, at least when the sun is very bright. I do it in this way: I obtain a few lumps of lime and slake it in a pail and employ it hot, placing it on the glass very lightly with a brush, and it lasts all through the summer. I have kept the fires in all through the summer. I find that it is best to do so, especially in changeable weather, regulating the heat by the valves. I know that there are various opinions as to bottom heat, but from experience I think there is little danger of having too much, provided water is supplied in proportion.

In concluding I will sum up the requirements of Cucumbers in a few words. To grow them well necessitates hard work, constant attention, judicious watering, regular syringing, liberal top-dressings, and fire heat according to the weather, but I make no attempt to keep the temperature at a fixed degree, as common sense tells me to do this must be wrong. In addition to the regular watering and syringing in hot weather the plants are greatly benefited by damping the paths and beds during the morning, or say about noon. Keep your plants pinched and tied regularly, and cut the fruit as soon as ready. Always close the house early before the sun loses its power, as by so doing you save much fire heat and benefit the plants.—STEPHEN CASTLE, *The Vineyard, West Lynn, Norfolk*.

JAPANESE ANEMONES.—I was very pleased to see these so prominently advertised in your columns last week, as they are plants of such sterling merit that everybody ought to grow them. Owing to the number of hardy and other plants now advertised and spoken of in the papers, it can be no small matter for anyone to select those which are really good and useful, as it is well known

that many of the so-called hardy flowers possess no decorative value; but if nurserymen, who know the value of plants and flowers better than most people, would only advertise those that are really good, they would do good service to all lovers of useful flowers. We have both the white and pink varieties of the above growing out of doors and under glass here, and for all purposes and all positions of a floral decorative character there are few flowers equal to them.—J. MUIR.

THE SNOWBERRY.

THIS shrub (*Symphoricarpos racemosus*) when in beautiful berry at this season occasionally proves very useful. In a few wreaths of choice flowers which have passed through my hands of late some of the clusters of this were greatly admired. I send you a few sprays, though this season I have gathered many much finer. Our plants for the last few years have been laden with white berries; indeed, I do not recollect ever seeing fruit so abundant. They are growing in the fowl yard, and whether with the hens being so much under them and the manure being washed down to the roots is the cause or not of the fertility I cannot say.—R. M.

[Such very fine pure white clusters of fruit as you have sent are valuable for many decorative purposes.—EDS.]

THE POTATO DISEASE.

THE theory which "INTERLOPER" has advanced about the disease being "caused by a rupture of some of the organs by a glut of rain during some period of the plant's growth" is ingenious; but to make it good it would require to be backed up by the necessary evidence, and it would also be necessary for him to be able to explain all the facts connected with the disease, and not to confine the proofs to a few of them. Let us examine his proofs a little—1, "The cells being ruptured after heavy rains." This may be so, but is the rain the cause of it? 2, "Gather from reliable sources the results of growing Potatoes under glass, and where they are free from excessive moisture, and the evidence will show the absence of disease." If Potatoes are kept dry under glass they are often free from disease, particularly in spring, but there are exceptions. Mr. Bréhaut in Jersey found his Potatoes badly diseased one year when grown in his greenhouse entirely sheltered from rain. The gardener to Lady Rolfe many years ago experienced the same thing with Potatoes grown in frames. How does "INTERLOPER" propose to account for these exceptions? This heading may be included under No. 2. Then, again, supposing heavy rains after muggy weather are the predisposing causes of disease, how does "INTERLOPER" propose to account for the circumstance that the Potato was grown for two centuries before 1845 without any of those evil consequences arising from gluts of rain of which he speaks? There are many other little difficulties attending the excessive rainfall theory, but perhaps the above will suffice for the present.—AMATEUR, Cirencester.

BULBS IN BEDS.

LAST year I had an American paper sent to me which gave instructions for planting a bed with bulbs so that it would be attractive over a considerable period. As the plan appeared worthy of trial I tried it, and as it answered my expectations I send it to you, as possibly if adopted it may give equal satisfaction to others.

"Make a round bed of any size, and plant an inner circular row of Crocus, and next outside a row of Hyacinths; then a second row of Crocus, and next one of Tulips. Continue this until the bed is filled—making every second row Crocus, and alternating Hyacinths and Tulips between them. The row on the extreme edge must be Crocus, and the space inside of the first row should be filled with Tulips or Hyacinths. The effect of a bed thus prepared is extremely pretty for a long time, and, thus arranged, it may remain undisturbed two or three years.

"Snow is no sooner gone than the bed is bright with the cheery little Crocus, which apparently covers the whole surface. These will hardly have passed away when we have a bed of Hyacinths in all their delicate lovely tints. The Tulips then form a climax of gorgeousness. The foliage of the Crocus, which is extremely delicate and pretty, is in perfection during the flowering of the Hyacinths and Tulips, and covers the bed with a lovely green carpet, taking away the usual bare look of bulb beds when out of their time of bloom. Still another succession might be had by scattering the bulbs of the Spanish Iris through the bed. They are perfectly hardy, with slender foliage, and furnish exquisitely beautiful flowers in every shade of blue, purple, yellow and white,

and even chocolate. These, following the Tulips, need only seeing to be appreciated.

"After the bulbs have finished blossoming the foliage should be allowed to ripen, to perfect the bulbs for another year; but the surface may be immediately picked over with a fork between the rows and between the bulbs, and *Portulaca* or *Petunia* seed may be scattered over the bed. These will be growing freely by the time the bulbs are gone. After the first year these latter will sow themselves and be ready to bloom early. If foliage beds are preferred, small plants of *Coleus*, *Cineraria*, and *Centaurea* may easily be planted between the bulbs, making the bed very ornamental for the remainder of the season."

I did not include the Irises, but I have no doubt whatever that they would have succeeded equally well, and I shall try them this year. The Tulips I employed were *Rex Rubrorum* and *La Candeur*, and their effect was very beautiful. The bulbs should be planted as soon as possible.—A STATION MASTER.

HOLIDAY NOTES.

WOOLTON HALL.

FROM Garston to Woolton is a distance of 2½ miles, and the district is one of the most pleasant in the neighbourhood of Liverpool. It is not necessary for me to give a description of the above-named place, as that task fell to the lot of an abler writer than myself, who last year gave your readers a concise and instructive account of nearly all the places of note about Liverpool.

At Woolton Hall there is so much that is good that it is difficult to decide what to place first, but what first struck me as being worthy of note were the Chrysanthemums. Hundreds are grown for specimen blooms, and scores of bushy plants for conservatory decoration. Mr. Faulkner grows three or four dozen each of white and yellow *Cedo Nulli*, and when arranged in lines in the glass corridor they have a good effect. The plants grown on single stems are of a character rarely to be met with as regards strength, and the abundant foliage is of the richest green imaginable, all the plants being of the most approved exhibition varieties. In the plant stove I noticed *Nymphaea caerulea* flowering in a tub about 40 inches in diameter and 14 or 16 inches deep. It is to be regretted that these beautiful plants are not more generally cultivated. In the greenhouse was a good plant of *Trachelium caeruleum* bearing its Statice-like flowers in great profusion. On the back wall was a large *Abutilon Boule de Neige* planted in the border, giving a useful supply of flowers for cutting. This is the way *Abutilons* should be grown where there is space for them. Perhaps that which gave me the greatest pleasure at Woolton Hall was a fine group of the blue and white *Campanula pyramidalis* 8 to 10 feet high, and arranged alternately in an octagon-shaped bed in the conservatory; the purity of the white combined with the rich blue flowers and the noble yet graceful proportions of the plants had a most charming effect. This *Campanula* may be grown from seed and flowered within eighteen months from the time of sowing. The seed should be sown at the same time and treated like early *Cinerarias*, growing the plants hardy and rapidly, which will readily be effected by giving light rich soil with exposure to light and air. They should be finally potted by the end of August, and if thoroughly ripened in the autumn they will produce their lovely flowers in due course the following summer.

The condition of the Peach and Nectarine trees in the houses reflect the greatest credit on Mr. Faulkner, who has been growing them on the extension system, and thus is rapidly covering the large trellises allotted to them, and producing good crops of fruit of the finest quality. The varieties chiefly grown here are *Belle-garde* and *Violette Hâtive* Peaches, and *Pine Apple* and *Pitaston Orange* Nectarines, four varieties that are not easily excelled for general culture. The young Vines in the vineries are in good condition, and promise at no distant date to produce fruit that will take prominent positions at some of the provincial shows. I take this opportunity of thanking Mr. Faulkner for the courtesy extended to me during my visit to Woolton Hall.

OTTERSPOOL.

This beautiful place loses none of its prestige under the superintendence of Mr. Lindsay, the worthy successor of Mr. Hinds. Strawberries in pots are all that could possibly be desired, with foliage of a size and quality rarely to be met with, and consequently having crowns of excellent promise. Strawberry forcing being a special feature at Otterspool, I naturally looked for something good in that line, and I admit that I was fully satisfied with what I saw. In cold frames were some very good examples of *Mignonette* grown in pots, and trained as pyramids 30 inches high. When specimens of this deliciously fragrant plant are wanted they should be grown on rapidly to the desired size

without receiving a check of any kind, the flowers to be constantly picked off until the size required is obtained.

Primulas are well grown here, as are also specimen plants of Chrysanthemums. In one of the Orchid houses I noticed a good variety of *Sobralia macrantha* in flower. Roses are planted in every available space in the cooler houses, and produce a continuous supply of flowers for cutting, chiefly *Maréchal Niel* and *Gloire de Dijon*.

There were some strong well-ripened Vines in pots in a span-roofed pit; and in an adjoining division was a plant of Black Hamburgh, bearing large bunches of first-class Grapes. The most pleasing feature, to my mind, out of doors was the roseery, where the Rose beds were carpeted with Stocks and *Mignonette*, Asters and *Phlox Drummondii*. The general keeping of these extensive gardens is very creditable to Mr. Lindsay.—J. U. S.

CHAPTERS ON INSECTS FOR GARDENERS.—No. 13. NEW SERIES.

ALTHOUGH it is an exceedingly scarce British insect, a few words of notice may be bestowed upon a remarkable beetle

allied to the Sunshiners referred to in our last article, especially as a naturalist (the Rev. J. G. Wood), has expressed his opinion that "an entomologist would be doing a patriotic act by bringing over a number of them from the Continent, and turning them out to get their living in England." For one thing he believes these beetles, were they established amongst us, would help to diminish the numbers of some of the hairy caterpillars that are known to be destructive to vegetation. As a rule birds avoid caterpillars that are hairy or spiny, and the Ichneumon flies also escape more frequently than other caterpillars owing to their protective coat. This beetle bears the name of *Calosoma sycophanta*, and it is about an inch in length, with a head and thorax of very deep violet, and wing-cases of golden green. Hence when a swarm

of the species is on the wing in one of those Fir woods to which they have a special liking, the display is very beautiful. Indeed it is asserted that were it not for the services of *C. sycophanta* and its larva many of the Pine and Fir woods of the Continent would soon be desolate owing to the rapid multiplication of several species of social caterpillars, particularly those of the Processionary Moth and the Gipsy. It is said that in some seasons the caterpillars appear in such hosts upon the Pines that a person walking through the woods hears on every side a creaking sound which is the result of the thousands of jaws busily at work. Upon these the larva of *C. sycophanta* makes attacks—an unpleasing creature in its aspect, black and scaly, but armed with mandibles which are most effective in caterpillar slaughter. It will gorge itself, not only with larvæ, however, but with pupæ also, and it not unusually seeks out and kills, besides these Lepidopterous larvæ, that of the Pine sawfly (*Lophyrus Pini*), an insect which does considerable harm, and which is not uncommon in Britain. But it is certainly curious that this useful beetle, so abundant in various parts of the Continent, should continue very rare here.

We proceed to another group of water beetles called Philhy-

drida (or water-lovers), resembling the water beetles previously described, but having short and clubbed antennæ. Some of these are carnivorous, though most of them feed upon vegetable substances growing or in a state of decay. Our largest British beetle next to the Stag beetle (*Lucanus Cervus*), a species of very different habit, is the black water beetle named *Hydrons picus*, an insect which may be introduced into the aquarium, for it merely nibbles the leaves of the plants, and will not wage war upon its companions, as does the *Dytiscus* or water tiger. The larva is predaceous, however, destroying water snails and various insects, and after a life of much longer duration than that of the beetle into which it develops, it forms a cocoon in the earth beside the stream that has been its home. There are several genera of much smaller beetles, concerning which we need only say that the majority have legs adapted for crawling as well as swimming, and their habits lead them to quit the water frequently, gliding amongst the moss and grass near ditches or in marshy places.

The beetles of the next family, the Necrophaga, come in closer relation to the garden and other haunts of man. "Lovers of the dead," or "lovers of filth," as another Greek name given to them implies, they are yet seldom unclean or offensive in themselves,

and in the great system of Nature they perform a duty that is by no means insignificant. Death and decay must occur in the animal and vegetable worlds, and many beetles have it assigned them as their life business to remove or decompose what might otherwise infect the air. A few of the Necrophaga have exceptional habits, but the bulk of them act as scavengers, the burying beetles being a leading type. These sturdy beetles of the genus *Necrophorus* are usually banded with yellowish red and black, as in that common species the Sexton, *N. Vespillo*. By means of a delicate sense of smell (as is supposed) burying beetles discover on the earth or on grass the dead bodies of small quadrupeds, birds, or frogs; and working generally in couples, though now and then a party of six or eight has been observed, they inter

Fig. 69.—*SILPHA QUADRIPUNCTATA*.

these in the soil. Should the object be lying on grass or stony ground the beetles will drag it, with some labour, to a spot where it can be conveniently interred. The principal part of the work very suitably is performed by the male insect, which sets about the task in a methodical way, first digging furrows round the animal, then burrowing beneath he throws up the earth so as to form a rampart about it; next he stands upon the animal and presses it down, but should it not seem to have sunk enough more earth is removed from under it, and finally it is covered with the earth, which is trodden-in by the beetles. All being now ready they descend to the carcase, upon which they feast, and in which the female deposits her eggs. The larvæ of burying-beetles are long and worm-like, the legs almost imperceptible; but on the segments are elastic horny plates, by which they push themselves along.

Beetles that are placed in the genus *Silpha* have had the English name of Sextons given to them by one author. The French name, equivalent to Shield Beetles, is more appropriate, for they have a flattened extension of the thorax that projects above the head; and although some of them hunt not dead animals, there is a great variety of habit amongst them. The *Silphæ* are smaller than the *Necrophori*, and very agile in their movements. *S. obscura* almost

everyone has passed or trod upon by the roadsides—an insect of a dingy black, about two-thirds of an inch in length, having three ridges on the wing cases. This insect and several of its brethren feed upon decaying substances, animal, or occasionally vegetable, a favourite mark of the larvæ being the stale marrow bones often thrown out upon rubbish heaps. The larvæ of the *Silphæ* resemble the beetles is being made for rapid locomotion, having long and spined legs; their bodies are, moreover, shorter and thicker than are those of the *Necrophori*, each side of the head is furnished with six eyes. *Silpha quadripunctata*, shown in figure 69, a little larger than life, is one of our useful beetles, red-brown spotted with black, and travels over the branches of Oaks and other trees devouring caterpillars. Wandering amongst the grass and low herbage the larva also preys upon such insects as it can overpower. But a less favourable account has to be given of the dark-looking *S. opaca*, the larva of which has been detected in the act of devouring the young leaves of Beet and Mangold Wurtzel. (See page 295.) Another species of *Silpha*, again, may put in a claim to be considered the gardener's friend; this is the small and smooth *S. lævigata*, which, in spite of their protective slime, grapples with good-sized snails and kills some of them. We dismiss this group of beetles with a brief mention of the "mimics," which have received their popular name from the readiness with which they "tuck in" the head and legs if alarmed, when as they lie motionless they resemble some inanimate object. Those in the genus *Hister* live upon decaying substances, and as they are often brought into gardens with manure suspicion attaches to them which they do not deserve. One small beetle of the group is an enemy to Truffles; however, it has curiously curved hind legs, and its colour is indicated by its Latin name of *Anisotoma cinnamomea*; it fortunately confines itself to this non-important vegetable.—J. R. S. C.

AT a meeting of the General Committee of the NATIONAL ROSE SOCIETY, held on the 12th inst. at the rooms of the Horticultural Club some matters of importance were decided. The Metropolitan Show will probably be held at the Crystal Palace on Saturday, July 2nd, and considerable alterations have been made in the schedule so as to give better opportunities for small growers to compete. The Provincial Show will be held at Sheffield on Thursday, July 14th, and an offer made by Manchester to incorporate an autumn show of Roses with their International Fruit and Flower Show in September next was accepted.

— AMONGST the many interesting exhibits at the International Food Exhibition held in the Agricultural Hall we noticed a FINE COLLECTION OF GRAPES which were contributed by Mr. A. May, Fruit Merchant, St. Swithin Lane, Cannon Street. They had been grown by Mr. Ward, gardener to S. N. Miller, Esq., Bishop Stortford. The size of the bunches and berries and the excellent finish indicated the careful and judicious culture they had received. The most noteworthy of all was a bunch of Syrian said to weigh 18½ lbs.; it had two immense shoulders, and was in very good condition. A bunch of White Niece weighed 11¾ lbs. in similarly good form. Two handsome bunches of Gros Guillaume weighed together 12 lbs., and three bunches of Alicante weighed 16 lbs., and for bloom and size of berries and well-formed bunches they could scarcely have been surpassed. Gros Maroc were also represented by a few bunches of moderate size, but with extremely large berries. Two Pine Apples, 7 lbs. and 7¾ lbs. each, with Pears, Apples, Bananas, Melons, Pomegranates, Brazilian Oranges, and many other fruits rendered this stand of especial interest to the horticulturist.

— IN the greenhouse at Kew THREE GOOD PLANTS FOR ROOFS OR PILLARS are now flowering most abundantly—namely, *Cestrum aurantiacum*, *Cassia Sophora*, and *Passiflora cæruleo-racemosa*. The *Cestrum* is very similar in habit, foliage and

shape of the flowers to the well-known *Habrothamnus elegans*, but the colour of the flowers is a rich orange yellow tint, very bright and distinct. The *Cassia* has bright green pinnate leaves and terminal clusters of pale yellow flowers. The *Passiflora* is well known as a beautiful floriferous hybrid between *P. racemosa* and *P. cærulea*. All succeed in a moderately rich well-drained soil.

— MR. C. SMITH describes in *The Gardener* as follows a fine crop of MELONS AT CARDIFF CASTLE:—"The plants, seven in number, were planted in a border 2 feet wide and 14 inches deep, in a compost of soil which had produced two crops of Melons before the crop I am going to describe. Mr. Pettigrew is not particular as to the quality of the soil he uses for growing Melons. His success depends more on giving the plants liberal supplies of liquid manure and light top-dressings, to induce root-action near the surface, than trusting to any special soil. Three crops were taken from the plants which I allude to—namely, eight fruit from each plant each crop, or twenty-four Melons from each plant, making a total of 168 fruit to the seven plants, which averaged 3½ lbs. each, or in all 588 lbs. Many of the fruit of the first crop were more than 5 or 6 lbs. each, but they were smaller in size towards the end of the season. They were, however, all presentable fruit, and none of them under 2 lbs. in weight, and of the very best quality. The variety which produced the enormous crop was Eastnor Castle, a green-fleshed kind, of which we have a very high opinion. Mr. Pettigrew devotes great attention to the cultivation of the Melon; and it must be gratifying to him, as well as to the many visitors who come to Cardiff Castle, to see annually such magnificent crops of Melons as are grown there."

— THE display of CHRYSANTHEMUMS IN THE INNER TEMPLE GARDENS, which annually attract so many visitors, is likely this season to be even more satisfactory than usual. The plants are in robust health, the foliage dark green, and clothing the stems well up to the flower buds, which are also exceptionally clean, stout, and promising. Mr. Newton very reasonably anticipates having a better show than he has had for several years, and judging from the general condition of the plants and the large number of buds they are bearing we have no doubt it will prove so. The plants are now under cover, and in the course of a fortnight many flowers will be fully opened.

— IN the MIDDLE TEMPLE GARDENS a glass structure has also been erected for Chrysanthemums, and Mr. Snelling the gardener in charge has over three hundred plants arranged. They are rather small and a little backward, but as the buds are showing freely there will probably be a good and satisfactory display.

— "L. R." writes, "One of the good qualities of CARPET BEDS is the long period during which they remain bright and effective. I recently observed an instance of this in one of the London parks, where the carpet designs were almost as attractive as they were a month ago, the *Alternantheras* not having been destroyed by frosts, and the colours remaining surprisingly bright." A manager of one of the parks informed us the other day that the carpet beds last rather too long: he wished they were over, as he wanted to prepare the beds for bulbs.

— A USEFUL hardy plant for flowering at this time of the year is *EUPATORIUM AGERATIOIDES*. It bears heads of white flowers very similar to those of *Eupatorium riparium*, but the leaves are much larger and ovate in form. The plant grows about 3 or 4 feet in height, and succeeds in any ordinary garden soil, affording a supply of flowers until destroyed by frost. Though it has been in this country about 240 years it is by no means so common as many other plants of much less usefulness.

— A NEW VINE PEST has made its appearance in the Rheintal, canton St. Gall. The disease is said to resemble in some of

its characteristics the Potato murrain, but it is much more virulent, the Grapes affected by it becoming rapidly putrid. Several vineyards have been completely devastated by the malady, which is believed to be of American origin.

— FROM a Japan paper we learn that at the Botanical Garden in Aichi, *ken*, an INDIAN TEA-PLANT, has been planted as an experiment. The leaves have lately been gathered and treated in the same manner as the Uji Tea, and it has been found that the product of dried Tea is greater in proportion to the quantity of leaves used than in the case of Japanese plants. Tea-growers are, in consequence, said to be devoting their attention to the new plant.—(*Nature*.)

— A CORRESPONDENT ("W. F. M."), who desires to form a LAWN TENNIS GROUND, asks what extent of lawn is necessary for carrying out his object. Perhaps some of our readers can supply the information required.

— AFTER several days of fine WEATHER that was generally very favourable to gardening operations, a change occurred on Tuesday last, when rain and snow fell in many places; yesterday (Wednesday) snow, rain, and sleet fell for a considerable time in the metropolitan district, quite putting a stop to planting and other outdoor work.

— Mr. W. ROBERTS, writing in reply to Rev. A. Fitch, states that after much research he has found the ORIGIN OF THE ASH-LEAF POTATO. "The old Ashleaf," he writes, "was raised from the seed of the Mouse Kidney at Retford, Nottinghamshire, in 1804 by a John Holberry, a shoemaker of that town."

— THERE were, says the "Prairie Farmer," 249 varieties of AMERICAN GRAPES exhibited at the recent fair of the Mississippi Valley Horticultural Society at St. Louis. This was probably the largest and finest show of Grapes ever made in the United States. We not unfrequently hear it remarked that we have too many varieties of Grapes in this country, but the Americans appear to excel us, for at our greatest fruit shows seldom more than a dozen varieties are exhibited.

— THERE has been issued the official report to the Indian Government of Dr. King for the year 1879-80, regarding the CINCHONA CULTIVATION in the GOVERNMENT PLANTATIONS in BENGAL. In 1879-80 the extended cultivation reached about 750,000 young trees, and a crop of 361,590 lbs. of dry bark was harvested. A new kind of Cinchona yielding the Carthagena bark of commerce was successfully brought into cultivation. At the close of 1879 a consignment of Calisaya bark was made to London for sale in the market. The amount of febrifuges used in Government hospitals and dispensaries in 1879 in substitution of quinine was 5,400 lbs. The average price of quinine in Calcutta in 1879 was 90 rupees per pound, and at that figure the saving effected by the native-grown substitute has been nearly £40,000. The saving in former years from the like substitution of the cheap and equally effective native for the imported and costly drug was about £80,000, so that to the end of 1879 the total saving was about £120,000, or about £15,000 more than the plantations have cost from their origin, including compound interest on outlay at 4 per cent. per annum. These results are gratifying, and in the future even larger savings are expected from the successful cultivation of the valuable Cinchona species (obtained through Kew) which yields the Carthagena or Columbian bark.—(*Pall Mall Gazette*.)

— A CORRESPONDENT of a daily contemporary writes:—"We have been spending the week rambling on foot among the MARKET GARDENS OF THE MIDLANDS. They are situated on the estates of Sir Francis Burdett and Sir John Harpur Crewe, in the neighbourhood of Melbourne, Derbyshire. Hereabouts the farmers

are not agriculturists in the strict sense, but gigantic gardeners. All the produce to be seen any day of the year at the shops of the huckster and greengrocer are here grown wholesale, acre upon acre. 'Long fields of Barley and of Rye,' as spoken of by the Laureate, are here transformed into vast enclosures of Cauliflowers, Cabbages, Celery, Onions, Potatoes, Carrots, Leeks, Gooseberries, Currants, Raspberries, Strawberries, and so forth. Splendid Cauliflowers, Cabbages, and Celery may here be purchased wholesale at less than a penny a head, thirteen to the dozen. Strawberries which have been known in the open market to fetch 8*d.* per pound have here been sold by the ton at 2½*d.*, while Raspberries have frequently proved such a glut that the growers allow them to rot on the trees rather than be at the expense of employing labour to pick them. The Celery rows here just now are a positive sight to witness. Earthed up as they are for bleaching or blanching purpose, the key is given to the mystery of successful cultivation—deep, loamy, friable soil. The landlords charge a good price for the land, but it grows good stuff, and the tenants do not complain. Their only present grievance is 'foreign competition,' which they say is eating them up, though judging from their portly persons and the establishments they maintain, we are rather inclined to believe that in this matter at least the farming mind is given to exaggeration."

— W. MCCORQUODALE, Wood Surveyor, Scone, Perth, writes as follows to the "Journal of Forestry" on the UTILITY OF ABIES DOUGLASII:—"I have every reason to believe that this will become the most remunerative tree of all our Conifers. One valuable advantage which it has over Larch and Spruce is, that in dry sandy subsoils, where those trees are generally affected with dry rot, the Douglas Fir will luxuriate admirably. Its healing power after receiving injury is very extraordinary. I have seen trees barked halfway round the stem in a manner that would prove fatal to any other Conifer, whereas in the Douglas Fir it heals over in two or three years. It is, too, a very accommodating tree, as it may be planted successfully at any season of the year. We have transplanted these trees from 6 to 10 feet high during the months of April, May, June, and July without a single failure. In 1857 we prepared, and enclosed with a fence proof against hares and rabbits, 13 acres of poor moorish soil, which had been cultivated as arable land. It was planted with Douglas Firs at 9 feet apart, and the intermediate spaces were filled up with Larch and Scotch Firs in equal numbers, as nurses, to 4 feet apart all over. The plantation is now twenty-three years of age, and the nurses are pretty well thinned out. I have just had some of the Douglas Firs measured, and many of them stand 40 to 45 feet in height, by 4 feet 3 inches in girth at 3 feet above the ground. We have now begun to use the thinnings of Douglas Fir as wire fence posts. In April 1878, upwards of twenty of these posts were put into a new wire fence, and were marked to test their durability, alongside some Silver Fir posts; the remainder of the posts forming the fence being of Larch. The Douglas Fir posts, although only of twenty years' growth, stood the driving into the ground as well as Larch of the same age could have done. They are wearing well, and show every indication of making durable posts."

— IN an excellent article in the *Cultivator* Mr. H. B. ELLWANGER, the able rosarian of the Mount Hope Nurseries, U.S.A., has recently discussed the respective merits of English Roses as compared with the same varieties grown in America. It appears that many of our finest dark Roses do not succeed well in America, neither does Madame Lacharme. After many instructive observations Mr. Ellwanger concludes thus:—"The National Rose Society has accomplished very great good, but we hope it will branch out into something wider, and use its influence to greatly shorten the immense list of varieties with which we are

now encumbered—varieties which are called distinct, but which have no real difference. What does a grower care whether one variety has smooth wood and another has thorns, if there be no essential difference in the blooms? If such a variety as Marguerite Brassac or Wilhelm Koelle do not show some marked improvement over their relatives, Charles Lefebvre and Alfred Colomb, they should be stamped out as early as possible. A committee of such men as Messrs. Paul, Cranston and Turner, who grow Roses on an extensive scale, have excellent opportunity of determining the value of new sorts at an early date. Add to these such judges as the President and Secretary of the Society, and the dictum of such a committee in relation to this and other subjects with which they are charged would be of very great benefit."

BRUSSELS SPROUTS.

IN the interesting chapter on Chiswick it is stated, on page 344, that the Brussels Sprouts generally are not buttoning well. I have a splendid lot, the produce of seed which is three or four years old. My sprouts were a failure last year, owing, as I believe, to the bad stock from which the seed came; and as I knew there was little or no new seed in the market to be depended on, I sowed some of the old lot last February, and have every reason to be pleased with the result. It is probable that Brussels Sprouts may need to be selected afresh in order to have them as good as they were before the series of bad seasons, and I should advise anyone who has a good stock to save some of it.—WM. TAYLOR.

FIG CULTURE IN POTS AND BORDERS.

TO have good crops of this luscious fruit under glass preparation must be made at the present time, and I will refer briefly to trees established in pots, and to planting in borders. Trees in pots intended for early forcing that have been placed in the open air to mature the growth will now require to be taken under cover to keep them from the autumn rains. Any thinning or pruning of the shoots, or top-dressing the surface of the soil, should now be attended to, and the trees dressed with an insecticide, so as to have them ready for forcing in November. Until then keep them cool and dry, but do not allow the soil to become dust dry at the roots. Trees permanently planted out in the borders will, except those that are late, be shedding their leaves; and the houses, though required to be kept cool by free ventilation in favourable weather, must be closed when it is wet.

Lifting and root-pruning should be attended to as soon as indications of the ripening of the foliage are apparent. This more particularly applies to trees that are very luxuriant and do not produce fruit satisfactorily. Planting new varieties or making fresh borders should be attended to as soon as the foliage commences ripening. For Figs a border of moderate size is most suitable, but it must be efficiently drained with 1 foot depth of rubble, as brickbats, &c., with pipes beneath to carry off superfluous water. The drainage should be secured by a layer of turves grass side downwards. The soil should be 2 feet deep, putting it in 6 inches deeper in the first instance to allow for settling, as it ought to be allowed to do before planting. Turfy loam taken from a pasture about 4 inches thick, chopped up moderately small, adding a tenth of old mortar rubbish, and about 15 per cent. of half-inch bones. A 6-foot border is ample for the usual run of trellises.

Brown Turkey is the most reliable variety, and a fitting companion is found in White Marseilles. Negro Largo also is excellent, and the Grizzly Bourjassotte is delicious. Trees only requiring surface dressing should be attended to before the leaves fall, so that the roots may not be disturbed too much before forcing commences, as is likely to be the case when top-dressing is deferred until after the leaves have fallen.—G. A. G.

LAWN MOWERS.

I AM afraid some of your readers north of the Tweed would open their eyes a little on perusing an article in your issue of the 7th inst. to find that they have had a "WYLD SAVAGE" amongst them in search of a subject, and that he could find none in "a' bonnie Scotland" worthy of notice but the pretty *Tropaeolum speciosum*. I hope hotel proprietors will take the hint and grow something more cheerful in their gardens than "annuals and weeds," for it is quite evident that they have had a depressing effect upon the mind of your worthy correspondent. Your readers cannot yet have forgotten the strain in which "WYLD SAVAGE" wrote but a few months ago on the beauty and grandeur of the

woods, not in their summer beauty, but in winter, when all is bleak and bare; but in the words of Norton—

"But for thy soul it still had warmth and power;
Not to its cheerless beauty wert thou blind.
To the keen eye of thy poetic mind
Beauty still lives, though Nature's flow'rets die."

Why did "WYLD SAVAGE" not give us some similar description of those many wild romantic spots to be found in Scotland? I am sure they would have been acceptable to the readers of the Journal, and would certainly have been more in unison with his *nom de plume* than the common matter-of-fact thing, a lawn mower.

Most of what your correspondent says on this subject is true, and I hope he will not take it amiss if I make a few remarks on the same subject, even if we do not quite agree. He warns us against purchasing machines with the knives on a fixed spindle. Few are made like this now, but I believe there are some that have the ordinary arrangement reversed—namely, having the knives fixed and the sole-plate moveable, so that it can be adjusted to the knives, which answers the same purpose. "An occasional general cleaning will be advantageous," falls short of my standard on this point. Every time a machine is used, be it wet or dry, it should be thoroughly cleaned before being put away in dry quarters. If this is not done it will soon become so clogged that neither oil nor elbow grease will make one go smoothly. And before being put away for the winter it should be taken to pieces, well cleaned, oiled, and prepared for work again. I am glad to see that makers are now beginning to find out the value of having all gearing enclosed, and if chains could be enclosed in a similar manner there would be less grounds for the complaints "WYLD SAVAGE" lodges against them.

I am quite of a different opinion with regard to collecting the grass. The appearance of the "wee, modest, crimson-tipped flower" I always consider a sign of poverty of soil, and to collect and carry away every week a crop of grass only increases the evil. It is our practice to mow every fifth day—namely, Monday and Friday in one week, and on Wednesday in the week following. By doing so the work is light, the little grass scattered about is never seen, but does a great amount of good to the turf, invigorating the grass, so that Daisies are not so much seen, and the frequent mowing keeps the flowers from showing so much. We only use the box amongst flower beds and by the edges of walks. I also fail to see how "WYLD SAVAGE" can expect a man and lad to do more work with a 16-inch machine than two men would do with a 12-inch machine each. It is a plain case of 16 inches and 24 inches. My experience leads me to advocate light machines, frequent mowing, and leaving the grass uncollected, which promotes a healthy growth, and keeps it of that dark green colour so essential to a well-kept lawn.—R. INGLIS.

YOUR correspondent "WYLD SAVAGE" states that when the chain of a lawn mower is worn and the clog moved back as far as it will go, and then worn again, that the chain is of no more use. Is it not possible to have a link taken out of the chain? I say Yes, and any country blacksmith can do it. File the ends of two rivets and draw or punch them out, and the link will drop out; then rivet the next link as before, and the cog will want sliding as when new. The chain will be found to work as well as when it was new, and not slip off when mowing banks.—GEORGE PICKER.

FLOWERS IN DUBLIN.

LOBELIA CARDINALIS, *L. ignea*, *L. syphilitica*, red, white, and blue vars., are very beautiful, so is *Tritonia Mc'Owani*, *Rudbeckia Newmanii*, and one of the finest of all white Composites, *Pyrethrum uliginosum*. All the Marguerites (*Chrysanthemum frutescens*, vars.) are very bushy and floriferous, but they attract the flies in swarms, and the star-shaped flowers are thus spoiled by their excreta. *Browallia elata* var. *caerulea*, sown in June, and the plants pinched back until a fortnight ago, are laden with flowers.

Rubus rosaeifolius, figured on page 281, is pretty. We have only the double form, and much wish to obtain the single-blossomed type, which fruits abundantly, and is then very ornamental. I saw this last plentifully around the hill villages in Borneo, at an altitude of 3000 feet. Perhaps it was originally introduced there, although now quite abundantly naturalised. Van Houtte advertised and figured the single-flowered type some six or seven years ago, but I never saw it in cultivation.

I have now a pretty hybrid *Calceolaria*, *C. fuchsiaefolia* (deflexa of "Bot. Mag.") × *C. Pavoni*. It flowers at 10 to 12 inches high raised from seed and planted out, and may be useful as a winter bloomer indoors; at any rate it is interesting as a distinct hybrid.

The weather has lately been very bright, and Dahlias, Everlastings, Asters, and *Lilium auratum* (late-planted bulbs) are even yet fresh and attractive.—DUBLINENSIS.

BEURRÉ BOSC PEAR.

LAST week we figured a new Pear of considerable merit; this week we submit an old Pear of proved excellence and usefulness. There are brighter coloured Pears than Beurré Bosc, but when in good condition few are of better quality; the tree is also a very good bearer. It is a favourite Pear in Kent grown as an orchard

standard, and it would not be grown there if it were not profitable. In northerly localities it requires a wall, but in most sheltered gardens in the midland counties it succeeds well as a pyramid. This is essentially a useful Pear, as it is a pretty constant bearer and the fruit can generally be relied on. In the "Fruit Manual" Beurré Bosc has four synonyms—Beurré d'Apremont, Beurré Rose, Cannelle, and Marianne Nouvelle; and it is described as follows:—"Fruit large, pyriform. Skin almost entirely covered with thin cinnamon-coloured russet, leaving here and there only a small portion of the yellow ground colour visible. Eye open, placed in a shallow basin. Stalk about $1\frac{1}{2}$ inch long, inserted

Fig. 70.—BEURRE BOSC PEAR.

without depression. Flesh white, melting, and buttery; very juicy, rich, and aromatic. A dessert Pear of first-rate quality; ripe in October and November. The tree is a good bearer, but unless grown against a wall or in a warm situation the fruit is apt to be crisp or only half melting. This, which is generally supposed to have been a seedling of Van Mons, was found a wildling at Apremont, in the Haute Soane, and was dedicated to Mr. Bosc, the eminent Director of the Jardin des Plantes at Paris."

SHOW POTATOES.

I AM glad to perceive from the courteous letter of Mr. Alexander Dean on page 346, that there were substantial reasons for doubting the distinctness of two of the varieties in the first-prize collection of twenty-four varieties at the late great Potato Show. "White Emperor," says Mr. Dean, "is just like Blanchard in form and outline," and the tubers of the former "showed discoloration because they

were large and forced nearer to the surface than the others." They were, therefore, according to Mr. Dean, just alike in form, and nearly alike in colour. I said no more than that, and further, I did not pass any opinion on the identity of the two varieties, and accounted for the opinions of others on the ground that I well know to be true, that "Potatoes vary much in different soils." The fact, however, still remains that all the other White Emperors were really white. These, therefore, had not been forced out of the surface of the soil, and thus the little problem is solved.

It appears there was still more reason for remarking on the very striking similarity of appearance between the Early Ohio and the Beauty of Hebron, for the principal difference, according to your correspondent, between the two varieties is in the haulm, that of the former being dwarfer, while the tubers on the average are rounder. I may remark on these distinctions that, as Mr. Beachey has observed, we do not eat the haulm; and as to the shape of the tubers, there were many examples of Beauty of Hebron in the

Show quite as "round" as the dish of Early Ohio in question. Although I did not touch one of them I saw several removed for the purpose of comparison, and noticed the unanimity of opinion relative to them. I never hinted at such a thing as "impropriety," for all growers are liable to purchase what is not actually a true stock, and exhibit the produce, as I have no doubt Mr. Dean did, honestly; and it is quite clear that the Early Ohio of Mr. Dean and the Early Ohio of Messrs. Daniels are not identical. The produce of both I assume will be sold, and we shall have two Early Ohios instead of one! If Mr. Dean does not think it of public importance that attention should be directed to a circumstance of this kind as soon as possible I venture to think he will almost stand alone among Potato cultivators. The parentage of the Lord Mayor was stated in a report of the meeting of the Royal Horticultural Society, held on July 27th, to be Extra Early Vermont and Early Market. Mr. Dean, however, now states that Early Rose, not Early Vermont, was one of the parents. Will he kindly say which is correct? Probably the latter is, but it would be well if the point were authoritatively settled, and no one can settle it so well as the raiser of the variety.

I may remind your correspondent that I was writing about Potatoes, not about exhibitors, and the best proof of my absolute impartiality is that I described one of Mr. Dean's varieties—Mr. Bresee—as a splendid long red kidney. Your correspondent does not object to this; yet when I with equal justice referred to the Lord Mayor as rather deep-eyed my statement is questioned! I will not say more on this point than that time will prove whether it is "rather deep-eyed" or not. I did not question its cropping character nor its quality, not knowing anything of either, and Mr. Dean's evidence on those points was not called for by my observations. I shall be glad if it proves a variety of real usefulness, and ranks in this respect with Schoolmaster, Magnum Bonum, and others. The latter variety I referred to in such a manner as to render it obvious that its omission from the short list of varieties that were shown in the greatest numbers or the best condition was a mere accident.

In some instances Mr. Dean appears to be very particular on the question of varieties being distinct, for he says, "Pride of America is but another Snowflake, and Edgeott Seedling and Yorkshire Hero are both Lapstones." There is about the same difference, and no more, between Early Ohio as exhibited by Mr. Dean and Beauty of Hebron as staged by several other exhibitors; but Mr. Fenn, one of the best judges of Potatoes in England, has said of the Lapstone that he considers it as near to perfection in quality as a Potato should be; can he or any unprejudiced judge say the same of the Beauty of Hebron? It is not good with me, and I shall discard it with several other varieties that are not fit to eat where a good Potato can be grown. I would ask, too, if the Yorkshire Hero is identical with the Lapstone, as Mr. Dean states, why both varieties are included in Mr. Dean's list of last year, and one priced at 1s. a peek more than the other?

Potatoes are quite sufficiently numerous without adding to the already too long list of varieties of questionable distinctness, numbers of which are not fit to be placed on a gentleman's table. I have proved this by the best of all tests, and the peremptory orders I have received to give the produce of so many of the varieties to the pigs.—A GARDENER.

PRUNUS DIVARICATA.

In the "Botanical Magazine" for the present month, plate 6519, is an admirable representation of the above handsome tree, which was briefly referred to in page 275 of the last volume of the *Journal of Horticulture*. In the descriptive remarks accompanying the plate Sir Joseph Hooker gives the following particulars—"This has been for many years one of the most conspicuous spring ornaments of the Royal Gardens, where it forms a dwarf tree, standing to the west of the Cactus house, near the fine specimen of *Pinus Coulteri*, and so covered with white flowers in March or April (according to the season) as to appear as if snowed over. The flowers appear with the half-developed leaves, but have never been succeeded by fruit. Whether this should be considered as anything more than the wild form of the *Myrobalan Plum*, *P. cerasifera*, Ehrh. (see tab. 5934), has been doubted by the excellent observer C. Koeh, as I have stated under the latter plant; and, indeed, the characters whereby most of the native Plums are separated are not of very much moment. With regard to *P. divaricata*, however, its leaves when full grown, broadening at the base, and appearing with its smaller flowers, and its fruit not being intruded at the base, together with its remarkable habit, would appear to constitute sufficiently marked diagnostic characters. The petals, which are almost orbicular in the Kew specimens, are more obovate in native ones from the Caucasus, collected by Hohenacker, and in others from the Copenhagen Gardens.

Prunus divaricata was introduced into England in 1822, according to Loudon, probably from the Dorpat Gardens, when under the direction of its describer Ledebour, and is a small tree 10 to 12 feet high and broad, forming a hemispherical mass on the ground with a singularly graceful ramification; according to Boissier, it has a very wide geographical range, from Macedonia to the Caucasus and Northern Persia. The specimen at Kew was procured by the late Curator, Mr. J. Smith, from Messrs. Osborn of Fulham, about thirty-eight years ago."

OLD VICTORY OF BATH MELON.

I DO not know the origin of this Melon. I imagine it must have been raised many years ago, and if I may venture a surmise, it has probably descended from seed imported from Cabul. I have, however, no hesitation in giving my opinion that the Melon sent out by Mr. Gilbert a year or two ago under the name of Netted Victory is a totally distinct variety. I grew the Netted Victory last year from seed kindly sent me by Mr. Gilbert, so that there ought to be no mistake about its being the true variety; and it proved in my hands worthless. It was white-fleshed, small (under 2 lbs.), without a trace of net, and the flavour most insipid, although in the same house and under the same treatment other varieties were grown which produced fruit with a flavour leaving nothing to be desired. Now the old Victory of Bath which I have grown produced a large, rather oval fruit, well netted, with deep green flesh and a luscious flavour—a fruit, in fact, worthy of being placed on any dessert table in the land. I also received from Mr. Gilbert seed of what he called Improved Victory of Bath; that also, I may say, resulted in disappointment. In the *Journal of Horticulture*, vol. xxxvii., page 6, Mr. Gilbert does not deny having artificially netted his Melon, and confesses that he makes a practice of doing so "to please the eye;" though that may be a matter of opinion, but it appears to me that, under the circumstances, Mr. Gilbert should not have sent out this Melon under the name he did, as, from the evidence before us in your pages, it would seem that the Melon in question is of a sportive turn, sometimes being netted, sometimes smooth.

I notice in *Journal of Horticulture*, vol. xxvii., page 281, Mr. Gilbert writes, "My Victory of Bath Melon has solved the great problem of pleasing everybody." It would be interesting to know which of his Victories it is that he alludes to, and how it became his. The simplest plan, I might suggest, would be for Mr. Gilbert to explain, if he can, the origin of his Netted Victory, as there can be no object in keeping the matter secret; but for my part I would recommend every Melon grower to stick to the old variety.

In conclusion I would remark that it is a great pity so many so-called new Melons are year after year brought out and certificated. Nearly every gardener tries to produce a hybrid of his own, and confusion becomes worse confounded. I have tried most of the new Melons, but there are very few I would care to grow a second time. The two best in green flesh of late years are Exquisite and William Tillery, and in red flesh are Read's Scarlet, and one I received from Mr. Gilbert called Excelsior. Mr. George Abbey's Read's × Beechwood × Victory of Bath is also excellent and equal to any off he above.—F. C. TAYLOR, *Montrose*.

As Mr. Iggulden has pointed out, Mr. Pettigrew has made a mistake by confounding Gilbert's Netted Victory Melon with Gilbert's Improved Victory of Bath. I grew the latter many years before the former was heard of, and so have numbers of other gardeners. The Improved Victory of Bath I have found one of the best growers, setters, and croppers of all Melons, and the fruit is of very good quality but does not net well. When the Netted Victory was sent out I naturally thought it was a netted form of the Victory of Bath but was disappointed. Mr. Gilbert selected a name for the newer Melon that no doubt accelerated the sale of the variety, but it was a mistake nevertheless. Although I write under the above heading I am unable either to state the origin of the "Old" Victory of Bath or the difference between that and the "Improved" variety: probably Mr. Gilbert could tell us this.—J. D.

I AM fully convinced I was wrong in my description of Gilbert's Victory of Bath Melon, and thank Mr. Iggulden for his courteous correction in last week's *Journal* (see page 345). It is unfortunate and misleading to cultivators that two Melons so distinct in form of fruit and flesh should have names so similar. I was misled by the name "Netted Victory" (as stated by Mr. Iggulden) and described it in my note, thinking it was the Melon in dispute—namely, an improved variety of the old Victory of Bath, though I could see no similarity between the two Melons, as I stated in my description of it.—A. PETTIGREW, *Cardiff Castle*.

OUTDOOR CHRYSANTHEMUMS.—Visiting Paris in 1878, I was

particularly struck with the fine blooms of the autumn and winter-flowering Chrysanthemums in the city public gardens; and when referring to those in your columns I drew attention to the desirability of growing the earlier Chrysanthemums in English and Irish gardens, so as to bloom during the month of October, and as far as possible into November. Usually we have no frost to destroy their blooms until the beginning of December in the south of Ireland. This was so last year, and I had some splendid blooms before that time. This year, if no severe frost comes before that time (and it will take several degrees to injure Chrysanthemums grown outside), I hope to have the blooming over of those outside.—W. J. M., *Clonmel*.

MORE ABOUT POTATOES.

In your issue of October 14th your correspondent Mr. R. W. Beachey, under the above heading, seems to me to be prejudiced against Scotch Champion and Magnum Bonum. He, however, begins by giving them an excellent character for quantity, and I think he is unreasonable to expect good quality regardless of the soil they are planted in. I should like to know a Potato with such a recommendation. These Potatoes are evidently not suited to Mr. Beachey's soil, so that if he can obtain any which will similarly resist disease I should advise him to make a change. My experience of them is that they will do well on a great variety of soils, being more accommodating in this respect than any other variety with which I am acquainted, the Magnum Bonum standing first.

A short time since I had the pleasure of lifting both varieties, and the additional pleasure of eating them very soon after they were lifted, under which circumstance I was surprised to find how good the flavour was; and this may be accounted for by the fact that the soil was very free. I have no doubt that in more retentive soil they would require storing before the flavour would be so good.

The crops were good and free from disease. The haulms of the Magnum Bonums were quite dead, but not those of the Scotch Champions. I, however, thought it wiser to take them up in fine dry weather than wait for the decay of the haulms, by which time I feared wet weather might arrive and disease follow.

Snowflake I have tried, but on rather tenacious soil, and found it so watery and flavourless that I did not grow it again. I have also tried several other varieties, but none have given me such great satisfaction as Magnum Bonum and Scotch Champion. Of the two I prefer Magnum Bonum, which is, I think, less liable to disease, suitable to a wider range of soils, and the tubers are of a handsome and more economical shape, add to which the important quality of earlier maturity.

I am of opinion that many Potatoes are unjustly condemned owing to their being tried on a soil unsuitable to them. I also think that there are very few varieties which, although they may succeed fairly well on retentive soil, do not prefer and pay better for growing on good free-working soil.—M. ANAROYD.

HARDY FRUIT GARDEN.

WHEREVER it may be intended to form plantations of young fruit trees, whether to be trained to walls or grown as standards, the ground should now be prepared for their reception. Soils having a heavy and retentive subsoil will require thorough and effective drainage; some light soils equally require draining to dislodge water from the subsoil, whilst soils resting upon gravel will probably not need it. It is useless attempting to grow fruit trees without efficient drainage to aid the percolation of water through the soil. For trees against walls nothing pays so well as a properly prepared border. If the soil beyond a few inches at the top be little better than brick clay the good surface soil should be laid aside, and as much of the clay removed as will give a depth of 30 inches; one half of the clay being burned will form an admirable substance to mix with the other half, and the surface soil forming, if the latter be turfy, an admirable compost for the roots of fruit trees without any addition of manure; but if the surface soil has been under crops an addition of fresh turfy loam will be decidedly advantageous. To prevent the roots pene-

trating the under strata the bottom may be concreted and sloping from the wall to the drain; 6 inches of rubble for drainage, secured by a layer of turves grass side downwards, will form a foundation too seldom laid, the compost being put in about 9 inches higher than the intended level to allow for settling. A 6-foot border for walls 10 feet in height, and 8 feet for those over 12 feet, is ample if that part is kept entirely for the trees; their roots are not then mutilated by frequent digging consequent on cropping with vegetables, which prevents the surface-rooting of the trees, the employment of mulchings, and the supply of liquid manure as may be necessary. The roots are then under perfect control, as when they have extended beyond the limit of the border proper any excessive luxuriance may be checked by cutting off the roots without giving a check to the trees, as would be the case with the roots deep and wide in a cropped border. Light sandy soils should have a liberal addition of turfy loam and well pulverised clay or marl. Manure is best applied at the surface, for in the soil it finally becomes a close inert mass. Soils deficient in calcareous matter will be benefited by the addition of a tenth part of old mortar rubbish or chalk. The trees can be planted as soon as the leaves have fallen, or if they have not to be moved any great distance as soon as the wood is ripe and the foliage showing indications of falling, and care must be taken to keep them as short a time out of the soil as possible. Planters should by this time have selected their trees, and must see when the time arrives that they are carefully lifted, the roots kept from exposure to the air, the trees carefully packed and forwarded with as little delay as possible. Avoid the "laying-in" process by planting them directly they arrive, spreading out the roots carefully and treading moderately, forming a basin if the ground be so dry as to admit of a good watering being given, which will tend to settle the soil about the roots. In this state they may remain a few days, when the basin should be filled and the soil be trodden firmly about the trees, securing them loosely to walls or trellises, or employ stakes where necessary, completing the operation with a mulching of partially decayed manure around the stems and outwards as far as the roots extend. Any vacancies that may exist upon walls, espaliers, &c., should have the ground prepared for filling them up with young trees by removing a considerable portion of the old soil, and supplying fresh turfy loam and such other substance as may be deemed necessary. It is always advisable to plant on slightly raised hillocks, especially where the soil is heavy. Where root-pruning may be deemed necessary to check excessive luxuriance, and to induce the formation of fruit spurs, it should be performed as soon as the wood becomes sufficiently firm to avoid shrivelling. Any useless or unnecessary shoots may be cut out of all fruit trees now instead of deferring it until the leaves have fallen, for as soon as the fruit is gathered the light and air thereby admitted will assist the ripening of the spurs and wood for next season's bearing.

FRUIT HOUSES.

Vines.—Where late varieties of Grapes are grown in quantity to meet the demand up to May the necessity for very early forcing to have Grapes all the year round is not essential. Of all late Grapes Lady Downes' is the most valuable, being a sure cropper and excellent keeper, keeping fresh and plump up to the end of May. When grown and ripened in strong heat the Muscat flavour is more pronounced than when grown comparatively cool. Next to this may be placed Gros Colman, magnificent in berry and bunch, and when well ripened it is first-rate. Gros Guillaume when well grown is a grand Grape, the two last requiring more time to colour and ripen than any other. Alicante requires heat to ripen it thoroughly, and invariably finishes and keeps well. West's St. Peter's is a fine Grape, and when well ripened will keep until April. Alnwick Seedling is likely to be a welcome addition. Trebbiano and Calabrian Raisin, with Syrian, are the best white companions, and when well ripened are of fair flavour. When the above or some of them are not grown in quantity preparation must be made for early forcing. The Vines having been pruned and the loose bark stripped off dress the rods with a solution of soft soap, 1 lb. to half a gallon of water, adding half a gallon of tobacco juice and as much sulphur as will bring it to the consistency of thin cream. If there be any mealy bug or scale add two wineglassfuls of spirits of turpentine, and brush it well into every hole, angle, or

crevice. The border, it is presumed, has been surface-dressed as previously advised. Fermenting materials, leaves, and stable litter well mixed should be placed on the outside borders previous to closing the house and commencing fire heat, the necessity for the latter being lessened by placing similar materials inside the house. Syringe the rods twice daily, and force but gently till the Vines show signs of breaking. Young Vines that have completed their growth should have the laterals gradually reduced to admit light and air to the buds and induce the earlier ripening of the wood. Vines in pots not required for early forcing should be placed under cover, a shed or other place cool and dry will answer, the roots being protected by straw or bracken. An open shed with a north aspect is preferable when growth is to be retarded for late spring planting or fruiting. Examine all ripe Grapes frequently, removing decayed berries, and ventilate freely whenever the weather is favourable, employing slight fire heat by day, when plenty of air should be given to expel damp; but in dull weather and the external atmosphere is charged with moisture slight warmth in the pipes without the ventilation is advisable.

Peaches and Nectarines.—Young trees frequently make strong wood, which require more time to ripen than moderate growths made by older trees. Trees of this description may have a trench taken out at about 3 feet from the stem all around, all the roots outside the radius being cut away. The trench should extend down to the drainage, and may remain open for about a fortnight, which will check any inclination to late growth and assist in the ripening of the wood; the trench should then be filled up again and rammed well down as the soil is replaced. The surface soil should be removed towards the stem of the trees down to the roots and from amongst them, replacing with fresh strong turfy loam with a sprinkling of about 12 per cent. of bone meal, ramming well down; this should be done before the leaves fall, and a good supply of tepid water being given fresh rootlets will be emitted at once. Allow no wood to remain in late houses that will need to be taken out at the winter pruning, but cut out all superfluous shoots, as with proper summer pruning little work will be needed when the trees are leafless. Any trees in late, and particularly unheated houses, glass walls or cases that have a tendency to late growth and imperfect ripening of the wood should have the roots carefully lifted, shortening the strongest and relaying them in fresh compost, after having put the drainage in good order. Ventilate fully day and night, and if fire heat is employed for ripening the wood turn it off at night. Proceed with the cleansing of the houses, the pruning and dressing of the trees as they become denuded of foliage; dress the trees, leaving nothing undone that is likely to have a deterrent effect upon the future increase of the pests infesting these trees, the most disastrous of which are red spider and brown aphids.

MUSHROOM HOUSE.

Continue to collect and prepare materials for making successional beds, and as the weather is becoming colder the beds should be increased in depth, so as to longer retain the heat and insure the more certain and speedy spread of the spawn. Care should, however, be taken not to place spawn in the beds at a higher temperature than 85° in the general body of the materials, allowing the bed to lie for about a week after being made, when the temperature can be ascertained and the spawning proceeded with as the circumstances warrant. It is essential that the materials be thoroughly consolidated, and to form a firm mass without being so moist as to destroy the spawn, or dry enough to prevent its spreading. In the case of beds that have been made and soiled some time the Mushrooms will usually appear in about six weeks, when the covering of hay or straw should be removed and the surface kept moist by damping lightly with tepid water from a syringe. Artificial heat from successional beds being made will not as yet be necessary, and damping of the house may not be necessary; but the temperature must not be allowed to fall below 50°, a mean of about 55° being most suitable, and a dry atmosphere should be prevented by damping available surfaces as may be necessary. Slugs should be sought for at night and destroyed. Woodlice are great pests. A little hay placed at the angle formed by the bed and walls will cause them to secrete there, where they may be destroyed

by pouring boiling water over them, a small quantity being sufficient to kill them.

PLANT HOUSES.

Stove.—Although shade is essential in the summer months, it is hardly possible in the winter to afford plants, foliage as well as flowering, too much light during the winter months. The glass, therefore, of this, and, indeed, all glass structures, should have a thorough cleaning both inside and out, and if this were done more frequently than it is, the general appearance of the plants would be better and their flowering capabilities increased. Many plants will grow freely and yet flower sparsely, which is mainly attributable to a deficiency of light for the solidification of the growth as made. The confined humid atmosphere necessary to be kept up for stove plants causes slime, &c., to form on the inside of the glass, to say nothing of soot and dust on the outside, and this takes more or less from one of the most essential elements of plant life—viz., light; besides, many stove plants are in active growth during the dull autumn and winter months, hence the importance of securing to them all the light possible.

Eucharis amazonica.—To secure a succession of flowers treat the plants liberally whilst making growth by keeping them well supplied with moisture both at the roots and in the atmosphere, feeding with liquid manure, maintaining a brisk heat, with plenty of light. When the growth is complete afford a rest of about six weeks' duration by keeping the plants somewhat drier and cooler; they will when placed in heat throw up their flower scapes in about three weeks. Plants that have completed their growth should now be rested by keeping them in a temperature of about 55° until the beginning of December, then place them in a temperature of 65° to 75°, and, if available, a bottom heat of not exceeding 90° at the base of the pots. Flowers will thus be obtained for decoration at Christmas and the new year.

Griffinias.—Seldom are these beautiful bulbous plants met with, and yet they are amongst the finest of autumn-flowering plants, expanding their blue and white-striped flowers in succession over a lengthened period. The individual flowers last in a cut state a week, and are of a soft violet colour with a white central stripe down each of its curved narrow petals, being well suited for bouquets. The umbels of flowers are produced somewhat like an Agapanthus, and the flowers open from September onwards. The natural season of growing is during the autumn and winter months, and should be duly supplied with moisture, never allowing them to become dry, providing a temperature of about 60° minimum in winter; and after the growth is complete, as it is about April, they may be removed to a greenhouse not having a less night temperature than 50°. Fibrous loam with a little sand suits them. The bulbs should be kept about two-thirds above the soil. Being slow growers they are some time in attaining to a flowering size—usually three years, during which they should be kept growing through the summer up to August in a cool stove, and then placed in a greenhouse for about two months, the temperature not being lower than 45° at night. Good drainage is essential, as during growth good supplies of water is necessary, and never allow the soil to become quite dry, or the foliage will suffer.

All winter-flowering plants should be kept well up to the light, to insure sturdy growth, large heads of bloom, richness of colour, with durability in the flowers. *Gesnera zebrina*, *G. zebrina splendens*, and *G. exoniensis* should be kept in plenty of light, not allowed to lack water, and be grown in a temperature of 60° at night. If in small pots supply with liquid manure. *Caladiums* will be going off; lessened supplies of water will be necessary, but do not withhold it altogether.

NOTES ON VILLA AND SUBURBAN GARDENING.

KITCHEN GARDEN.

Beet and Carrots.—It is now advisable to lift and store the roots of these, as the former are liable to injury from severe frosts, and the latter when left in the ground are much infested by insect pests, indeed are already much damaged in this respect. Select a dry time for the work, and after having twisted off the tops of the Beet, and cut off those of the Carrots to near their junction with the roots, lay them in heaps for a few days in order that they may dry thoroughly previous to being stored. The tops should be thrown over the heaps

in the evening, and only taken off during fine days. When found to be dry, either pack away in dry sand in a shed, outhouse, or dry cellar, or they may be built into conical-shaped heaps on a dry spot, covered lightly with long fresh straw, over this being thrown a layer of earth to be well beaten on. The straw, where it meets at the points, should be arranged above the soil so as to form a funnel, which, though impervious to rain, will yet form an outlet for any vapour, which, if confined, might lead to fermentation. When lifting the Beet select all the smallest roots with foliage intact, and bed them in till they can be used in the flower garden in such a manner as will shortly be advised.

Late Potatoes.—Nothing is to be gained by leaving these in the ground after this date, and much may be lost by damage from severe frost. All that are now sound may be safely stored away. The ware of those of table size should go into one heap, and the middlings into another, or at all events enough of these for next year's planting, and the chats, or the very smallest, be given to the pigs or boiled for the poultry. Potatoes may either be stored in heaps in dry sheds, where they can be well covered with straw during the prevalence of severe frost. Unless the sheds are much sheltered and well built it is really advisable to line the walls and floors with straw as the tubers are being put in, as this may eventually save much labour. Failing sheds they may be thrown into heaps, covered with straw, and when dry covered with earth, leaving the funnel outlets as advised for the Beet and Carrots.

Various.—Parsnips are usually left in the ground, the only effect that frost has on them being to make them sweeter. In some instances they are lifted and stored in common with the above kinds. Turnips, again, are perfectly hardy in the southern counties, and may be left on the ground. They should, however, be lifted and stored if found to be growing too large, especially if the successional sowings fail. The autumn Cauliflowers are turning in almost simultaneously, and to prolong the crop it is advisable to lift some that are not very forward, and to bed them in where they will be cooler and also convenient for covering over during frosty nights with mats or other material. The caterpillars must still be looked after, as they soon disfigure Cauliflowers. Endive is now becoming extremely useful. The Moss-curled requires but little blanching, but the Green-curled and other large varieties should, when dry, be either covered with tiles, boards, or pots, or be tied up with matting in the same way as some Lettuces are tied. The Broad-leaved Batavian are the hardiest, and therefore should be reserved for the very latest supply. It is very advisable to lift a quantity of each variety, also of any full-grown Lettuce there may be, and pack away rather closely in a frame. A great quantity can be stored in a three-light frame; if occupied previously with either Melons or Cucumbers so much the better, as the soil will suit them. To avoid bruising the leaves lightly tie up with matting; lift with a good ball of soil, pack them in closely, loosen the ties, and water in should the soil be dry; give abundance of air, blanch them as required, and look closely after mice, as they are very fond of the hearts. Endive may also be stored in open sheds, but they are much crisper taken from the moist frames. Continue earthing up Celery as the inner growth advances, always selecting a dry time for the operation, preventing as much as possible the soil running into the hearts, and rounding-off as well at the final earthing-up. The Asparagus when quite yellow should be cut down, and then all weeds cleaned off, a good dressing of half-decayed manure given, and cover lightly with soil taken from the sides or otherwise. The decaying leaves of Brussels Sprouts and other winter greens and old Cauliflower stalks to be cleared off.

GREENHOUSES.

Potting Bulbs.—The present is a good time to pot those not intended to be forced, which in the case of many amateurs will include the whole stock of Hyacinths, Narcissuses, Tulips, Crocuses, Snowdrops, Ixias, Lachenalias, and Scillas. The soil suitable for the whole may consist of two parts good turfy loam to one of well-decomposed horse droppings or other manure, with a good addition of sharp sand or road grit. The pots must be clean and well drained, and in potting always place some of the roughest of the soil over the crocks.

Hyacinths.—For ordinary decorative purposes the 5-inch pots will

be found the best size in which to grow these, but 6-inch pots are usually preferred for those grown for exhibition, and which as a matter of course are selected bulbs of the best description. When potting fill the pots nearly full of soil, sprinkling some sand in the centre, on this place the bulb, and press it firmly into the soil till it is very slightly below the level of the rim, the bulb being finally about three parts covered with soil. It is very important that they be potted somewhat firmly, or otherwise when the roots start they are apt to raise the bulb, which necessitates repotting.

Hyacinths in Glasses.—To prolong the display it is advisable to place bulbs in the proper and easily procured glasses at intervals of about fourteen days. The glasses should be filled so that the water nearly touches the bulb, and be at once placed in a cool dark place for a few days to induce the formation of roots prior to the expansion of leaves and flower spike.

Narcissus.—Strong varieties of these, with corresponding large bulbs, may be either grown singly in 5-inch pots or three bulbs in 8-inch pots. Pot similarly to Hyacinths.

Tulips.—These may be grown either in 5-inch or 6-inch pots, placing three bulbs in the former and six in the latter, one in the centre and the remainder disposed round the sides. They should be firmly pressed into the soil, allowing the points to protrude slightly, and the fullest sides of the bulbs should be on the outside, so as to give the points and consequently the blooms an inward tendency.

Crocuses and Snowdrops.—The best sizes in which to pot these are the 4-inch and 5-inch pots, the number placed in each varying according to the size of the bulbs. As a rule four or six of the former may be placed in the respective sizes, and the Snowdrops and Scillas somewhat thicker.

Lachenalias, Ixias, and Sparaxis.—These are not quite so common as the foregoing, but all are worthy of more extended cultivation. Place six or seven of the first in 5-inch pots, and three of either of the other two in 3-inch pots, or seven in 5-inch pots. The Lachenalias may be disposed all over the under sides of hanging baskets, and when thus employed are remarkably effective.

TRADE CATALOGUES RECEIVED.

Francis and Arthur Dickson & Sons, The Upton Nurseries, Chester.—*Catalogue of Select Roses.*
George Bunyard & Co., Maidstone, Kent.—*Catalogue of Fruit Trees.*
George Cooling & Son, Bath.—*Catalogue of Roses, Fruit Trees, and Shrubs.*

** All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Tea Rose Election (Planter).—The varieties named in the list published last week were selected for their general usefulness, and not for their value as exhibition blooms. They will be therefore admirably adapted for your purpose, and you may safely plant as many of them as you require in your garden in Surrey. The result of the election of twenty-four varieties will probably be published next week.

Zonal Pelargoniums in Winter (G. S.).—If you desire the plants to flower freely they must have a very light position in a house in which the temperature never falls below 45° at night, and if it is 50° in mild weather all the better, with a proportionate rise during the day. Some varieties will flower in a cooler temperature, but will not possess the freshness of growth and size of trusses that render the plants so striking in midwinter. We have seen Mr. Cannell's Pelargonium house a "blaze of bloom" in January, the trusses of some of the varieties being 6 inches and more in diameter, and the colour extremely rich.

Mexican Potatoes (Henry Peto).—These are referred to on page 176 of our issue of August 19th, 1880, as being grown successfully by Captain Mayne

Reid at his residence near Ross. We do not know whether the Captain has seed for disposal, nor do we know from whom else seed can be obtained. A letter directed as above would no doubt find its destination; we do not know a more precise address.

Climbing Roses for Cool House (*S. U. S., Walsall*).—You do not say what colours you require, but the following three varieties will probably give you satisfaction:—*Maréchal Niel*, *Gloire de Dijon*, and *Beauty of Cheshunt*.

Clematis Star of India (*J. Lawson*).—This is an excellent variety, but by no means so "new" as you suppose. It was raised by Mr. Cripps of Tunbridge Wells, and was certificated in 1867. It flowers in the autumn at the same time as *C. Jackmanni*.

Pruning Coleuses (*J. Hope*).—The plants may be moderately pruned provided you have a house with a minimum temperature of 60° in which they can be placed; but if you have not such a heated structure, pruning would accelerate the decay of the branches and perhaps cause the death of the plants.

Wholesale London Seedsmen (*E. J.*).—Mr. Legerton's address is 5, Aldgate, E.; Messrs. Hurst & Son, 152, Houndsditch, E.C.; Wrench & Sons, 39, King William Street, E.C.; Mr. Cooper's, 90, Southwark Street, E.C.; G. Gibbs & Co., 26, Down Street, Piccadilly, W.; T. Gibbs & Co., 47, Half-moon Street, Piccadilly; Nutting & Sons, 60, Barbican, E.C. You will find several other addresses in the "Horticultural Directory," which will very shortly be published.

Tubs for Myrtles (*T. A. B.*).—We are unable to recommend a maker of these articles; but any intelligent carpenter could make square tubs, plain or ornamental. Those of large size should have stout corner pieces to act as legs, and the thickness of the sides must be determined by the size of the tubs. Pitch pine makes excellent tubs, which can be either stained or painted. Round tubs of any size and pattern can be made by coopers, but the cheapest plan is to purchase paraffin casks and cut them in halves; these are very durable, and suitable for plants and shrubs.

Quinces and their Uses (*G. S.*).—The fruit of the Quince you have sent us is less than one-fourth the size of a fully grown and ripe fruit, and is the product of a late summer, not an early spring blossom. Quinces are used in various ways. They are commonly used in very small quantities in Apple pies; then there are Quince cakes, Quince cream, Quince marmalade, Quince jelly, Quince pudding, Quince tart, as well as compôte of Quinces, syrup of Quinces, pickled Quinces, &c. But though their uses are so varied the fruit is not largely used, and one tree is generally sufficient in most moderate-sized gardens. The trees require no pruning, and when laden with large yellow fruit they are very ornamental.

Lifting Vines (*W. F. M.*).—Your Vines can no doubt be greatly improved by making a new border as you propose, and placing the roots about 6 inches from the surface; but without seeing the old Vines we cannot state whether it would be preferable to replant them now, or obtain young Vines in pots and plant them in the spring. Cannot you obtain the aid of a practical gardener in your neighbourhood to inspect the Vines and advise you on the subject? If you lift the Vines you should do so at once. Old Vines when lifted often produce excellent Grapes, but young Vines eventually produce the finest bunches. Your proposed plan of making the border is good, but it will not be necessary to make it of the full width the first season. See what is said on this subject on page 227, the issue of September 9th.

American Blight on Apple Trees (*F. J.*).—The shoot you have sent us is infested with this destructive insect (*Aphis lanigera*). All such shoots as the one before us, which is an unripe secondary growth produced after summer pruning, we should cut off at once and burn; their removal now cannot possibly injure the trees, and you would quickly destroy thousands of insects. As soon as the leaves have fallen from the trees dissolve soft soap at the rate of 5 or 6 ozs. to a gallon of water, and to each gallon of the solution add a wine-glassful of paraffin, and apply the mixture to every portion of the wood with a brush, forcing it with especial care into every crack or inequality in the bark where the insects lurk and pass the winter. By adopting this practice you will reduce considerably and possibly extirpate the pest. It does not matter which way you train the cordons—train them to the south. The angle you name is correct. The Durondeau is a very handsome and excellent Pear, and will succeed well on the aspect you name in most districts. Your other question shall be answered next week.

Summer-pruning Fruit Trees (*G. S.*).—The condition of your trees ought to prove whether your system of shortening the extremities of the shoots in summer is right or not. If your object is to have dwarf compact trees, and these are studded with blossom buds, your pruning will have proved correct. If large specimens are desired capable of producing a bushel or two of fruit each, then the extension shoots must not be shortened nearly so closely. Our plan is to let them grow until about the middle of August, and then pinch out the tips of those that exceed 18 inches in length, as growth made after that time seldom ripens. If trees are at all luxuriant your close mode of shortening the branches would not result in the production of fruit spurs unless root-pruning was also adopted. You may cut down your Oleander now, and in due time it will produce fresh growth, which must have full exposure to light.

Buffalo Horn Manure (*B. G., Fulham*).—You are quite right in your assumption that the value of horn shavings as manure has been long known, although the above fertiliser was only put prominently before the public two or three years ago by Mr. Wills. Twenty years ago a book by Dr. Lancaster on "The Uses of Animals in Relation to the Industry of Man" was published, which contains an instructive chapter on "waste." After referring to the usefulness of various substances thus usually denominated, the author observes: "Commerce aids in the profitable avoidance of 'waste.' Forcibly was this enforced on our attention in what has so wrongly been styled 'that waste of water the Atlantic.' We there fell in with a vessel, and when hailed as to here, where from, where to, and purpose, the reply was 'From Miramichi to Belfast with buffalo tips.' The world was circumnavigated that the tips of horns might be converted into handles, and their shavings would be mingled with the manure heap." Horn shavings are valuable as manure because they slowly decompose and give out ammonia for a very long time. They also contain a small quantity of carbonate and phosphate of lime.

Apples for Orchard (*P. Gravel*).—We desire to give a reply that will be useful to you, and we do not feel that we can do so without more precise information relative to your requirements. If you require as many varieties as possible without reference to their bearing qualities you will find them in any good nurseryman's catalogue, with their period of use; but if you wish to grow those varieties that are the most profitable for sale, or for affording you a supply of good fruit for home use, you will err by growing "all kinds of late Apples for kitchen and culinary purposes," as those would number 150 varieties, many

of which, though possessing some points of excellence, would not occupy the space so profitably as others. If you will state the object you have in view and the number of trees you require we will make a selection of those varieties that we think will best answer your purpose. We presume by "late varieties" you mean those that will afford a supply of fruit from November till May.

Podophyllum peltatum (*R. C., Kensington*).—The plant to which you refer is included in the natural order Ranunculaceæ, and is known as the May Apple and the American Mandrake. The medicinal substance Podophyllin is an extract from the dried rhizome and is employed as a purgative. The fruits when ripe are yellow and about the size and shape of an egg, being known in North America, of which the plant is a native, as Wild Lemons.

The "Cottage Gardeners' Dictionary" (*A. J. Long*).—A new edition of this work is in preparation, and the publishers are endeavouring to have it ready for distribution early in 1881.

Fruit Trees for Training to Walls (*W. W.*).—For the south aspect:—*Apricots*: Oullins' Early, Kaisha, and Moorpark, two of each; and one Peach Apricot; May Duke and Governor Wood Cherries, with July Green Gage Plum. You may omit a Cherry, and have Green Gage Plum; or if you want the south aspect all Apricots add to those named St. Ambroise (one) and Hems-kerk (two). South-east aspect:—*Plums*: Green Gage, Kirke's, Jefferson, Coe's Golden Drop, Denniston's Superb, De Montfort, Guthrie's Late Green, Transparent Gage, and Ickworth Impératrice, all for dessert; for cooking, Early Prolific, Victoria, Prince Englebert, and White Magnum Bonum. If these would be too many Plums substitute the Pears Jargonelle, Benrre Superfin, Marie Louise d'Uccle, Marie Louise, Van Mons Léon Leclerc, and Joséphine de Malines. We should, however, keep the Pinnas and add a Cherry—viz., May Duke. South-west aspect:—*Pears*: Jargonelle, Clapp's Favourite, Williams' Bon Chrétien, Beurré Superfin, Louise Bonne of Jersey, Gratioli of Jersey, Marie Louise, Hacon's Incomparable, Beurré Diel, Beurré Bachelier, Van Mons Léon Leclerc, Glou Morceau, Joséphine de Malines, and Bergamotte d'Esperen. *Apples*: Cox's Orange Pippin, Ribston Pippin, Golden Pippin, and Cockle Pippin. North aspect:—Morello Cherry is the best, and bears more satisfactorily than any other. Jargonelle, Williams' Bon Chrétien, and Comte de Lamy Pears also succeed; with such Cherries as Empress Eugénie, May Duke, and Late Duke; and Plums—Mitchelson's, Gisborne's, Prince Englebert, and Victoria.

Jerusalem Artichokes (*M. A., Belfast*).—These are greatly relished in many places cooked in various ways, but more especially in soups. Could the use of them be made popular, they would be no bad substitute with those who prefer a waxy Potato to a mealy one. They produce best when planted afresh every year in rows 4 feet apart, and 18 inches from each other in the row; but they will stand for years in the same ground, and afford plenty of produce, only the tubers will not be so regular. We have never known disease to affect them, and we have scarcely ever seen the tubers interfered with, except by rats and pheasants. We have often been surprised that they have not been more planted in the open parts of covers and game preserves; the stems would give shelter, and the roots abundance of food.

Plum Tree Unfruitful (*S. P., Notts*).—Your Green Gage would, no doubt, be very much improved by taking it up, bringing the roots nearer the surface, and giving it a little fresh soil to grow in. The present is a good time to do it. First unmail the tree from the wall, only leaving a few of the principal branches secured to the wall to prevent them from being broken. Dig a trench all round the tree 2 feet deep, or as deep as the roots, and about 6 feet from the stem; then with a fork work the soil carefully away from the roots, always drawing the fork towards the outside of the trench. When the soil has been taken away to within a foot or so of the stem the whole may be carefully lifted up. If the tree is a heavy one it must be lifted by means of a lever. This should be done gradually, and as the tree is raised soil should be placed beneath it. In raising the tree see that the branches that are left fastened to the wall are suffering no injury. As soon as the tree has been raised to the desired height spread the roots carefully out, sprinkle some fine soil in amongst them, and frequently shake them with a small pointed stick so that the soil may become settled about them, taking care to keep the points of the roots the lowest. As soon as all the roots have been properly covered with soil give the tree a good soaking of water, then add more soil, and finish the operation with a thick mulching of rotten manure. If the weather remains dry syringe the tree two or three times daily. The roots will at once commence growth, and the crop next year will not be injured if the operation is performed with care.

Trees and Conifers for Screen (*An Old Subscriber, Plymouth*).—There is only one Poplar that will be suitable for "planting close to a wall with a row of Conifers a few feet in front of them," and that is the Lombardy Poplar (*Populus fastigiata*). This is a quick and very close grower, and planted 6 feet apart would soon form a close hedge and require no pruning. You could take off the tops of the trees at any height required. The Black Italian Poplar (*P. monilifera*) is perhaps the quickest grower of all trees. The rate of growth in good soil near London is thirty and upwards in seven years. It bears cutting well, but much labour would be involved in preventing it injuring the Conifers a "few feet in front of it," and also encroaching on your neighbours' property over the wall. Poplars can be removed when of large size, but no one could say that trees 20 feet in height would be safely transplanted and grow freely without seeing them, or knowing the nature of the soil in which they are growing and the treatment to which they have been subjected. The distance for planting can only be determined, for your purpose, by the size of the trees when planted. This species is eight or ten days later in producing its leaves in the spring than the Lombardy Poplar. If your space is as limited as your letter implies we think the tree last named will be the most suitable for your purpose, and as quick growth is an object the soil should be well trenched to a depth of 2 feet, and as wide as possible. *Cupressus macrocarpa* grows much more rapidly than *C. Lawsoniana*, but large specimens of the former do not transplant well. Small examples planted 6 feet apart in good soil would soon form a hedge 20 feet high that would require no clipping. Lobb's Arbor-Vitæ (*Thuja Lohbiana*) is a beautiful hardy free-growing Conifer—close, dense, and elegant. It is highly suitable for a screen, and very ornamental. We doubt if any other Conifer would answer your purpose better than this; although it does not grow so rapidly as *Cupressus macrocarpa* it is not injured by the most severe weather.

Burning Soil (*T. A. Bowdon*).—If you can burn the soil that you have hitherto failed to render fertile, you will no doubt render it immediately and permanently productive. We know of no greater success in burning soil than that of Mr. David Thomson of Drumlanrig, when he was gardener at Dyrham Park near Barnet, and his process was described as follows, and is reprinted from page 17 of our little manual "Manures for the Many."—"As soon as a quarter in the garden became vacant, a fire or two were started, according to the size of the quarter. When only one fire was required, it was started in the middle of the quarter. The site for the fire was first trenched to the depth of 2 feet 9 inches, turning the top spit (which had through a long course of years

been improved a little by liming, the addition of ashes, road scrapings, &c.), into the bottom of the trench, taking out the two bottom spits for burning. So thoroughly clayey was the greater part of the soil moved, that the men had to dip their tools in a pail of water at every lift, to make the next spadeful slip off the metal. On this site the fire was commenced. Wood which was only fit for charring or firewood, and which is generally plentiful enough about most gentlemen's places, was used. In that locality coal was costly, and not so effective in this case as wood; the latter also affording in burning a desirable quantity of potash. The site for the fire being ready, a little stack of wood was formed 5 feet in diameter at the base, tapering cone like to the height of 5 feet, beginning with a few dry faggots in the middle, and finishing with stronger junks of wood round the outside. All round this stack of wood a coating of the clay was laid to the depth of about 1 foot. It was found best to pack it on in lumps as it was turned out of the trench. When this was done the wood was set fire to at the centre, and long ere the wood was all consumed the clay caught fire and burned freely. As soon as the first layer was nearly burned through another layer was added all round, which in its turn soon burned through also. The fire was then broken down with a strong iron-handled hoe, for the double purpose of adding more wood to quicken the fire and enlarging the basis of operations. After the fire was thus set agoing the wood was of necessity laid horizontally over the burning heap, putting the strongest pieces of wood next the burning mass, and finishing off the layer with the smallest, to prevent the clay from lying too closely to the wood and obstructing the draught necessary to combustion. In the meantime trenches were opened at the extremities of the quarter, and the clay taken out, as already described in making the site for the fire, and forwarded to the fire, there being the solid undisturbed surface to wheel it over, and the distance lessened as the fire became larger and required more feeding. But to return to the fire. When it was again found necessary to break it down for the purpose of extending the base and increasing its capacity for consuming the clay, another layer of wood was added, and then a layer of clay over the surface, and all round the outside of the heap. After this, as the layer of clay was burned through, another was packed on all over and round without any wood, and so on with two or three layers, till it became necessary to enlarge the base of the fire, by drawing it down from the top, then more wood was added; and from the great power which the fire attains it is necessary to have plenty of clay and men at hand to cover over the wood quickly, or it would be consumed without doing much good; and so this process was continued till the necessary quantity was burned. I have frequently had three great fires going at a time, on to the tops of which I have wheeled layers of clay to the thickness of 3 feet and more at a time. When the fire became powerful it formed a solid pile of fire, which very soon worked its way through thick and successive layers of clay, transforming what was once an insoluble, wet, tenacious paste, into a heap of material greatly altered in its mechanical properties, and with a great capacity for the absorption of ammonia, besides being mixed with charred wood and potash. As soon as the heap was sufficiently cool to be moved it was wheeled back over the surface of the quarter and regularly spread, and the large lumps broken up. On the surface of all was wheeled a garden rubbish heap, rotten leaves, road scrapings, dung, and other decayed vegetable matter that could be obtained. A trench was then opened at the end of the quarter, and the whole was turned over and mixed the same as is done with a compost heap, to the depth of the original clay, which was forked up as well as it would allow at the bottom of each trench. This formed a staple on which almost any crop that could be put on it in the way of vegetables grew with such a luxuriance as I have never seen equalled either before or since. I have seen Brussels Sprouts over 4 feet in height studded with hard sprouts, more like a rope of Onions than anything else. Peas, Carniflowers, &c., were amazingly fine crops. One quarter which I burned in 1854 had the finest crop of Carrots that could be desired, and to have attempted such a crop on it previous to its being passed through the fiery ordeal would have been in vain."

Tokay Wine (*Customer*).—Apply to any leading wine merchant. Tokay is a district of Hungary. The wine is the produce of various kinds of Grape, but the soil is peculiar, being of volcanic origin. The best vintage is not at Tokay, but in a neighbouring district called Tallya, and was celebrated as long since as the sixteenth century.

Names of Fruits (*G. Picker*).—1, Wyken Pippin, very fine; 2, Unripe, perhaps the Old Man Apple; 3, Gravenstein; 4, Winter Peach; 5, Edinburgh Cluster; 6, Striped Becfing, richly coloured. (*Mrs. R. W. H.*)—The Pear is Nouveau Poiteau.

Names of Plants (*J. C., Clonmel*).—The specimen you sent was so much withered that its name could not be determined with certainty, but it resembles *Silene conica*. (*No Name*).—1, *Adiantum concinnum*; 2, *Pteris serrulata cristata*; 3, *Pteris serrulata*; 4, *Rondeletia speciosa*.

POULTRY, PIGEON, AND BEE CHRONICLE.

ROTATION FOR CROPPING LIGHT SOILS.

(Continued from page 360.)

AFTER having noticed the principal rotations on light chalk soils advocated and practised by the most experienced farmers, we will now describe in a similar manner the most valuable rotations adapted for the sandy and light soils, commonly called the Bagshot sand, much of which was formerly in heath and wastes, used chiefly for the rearing of Grouse, and warrens for the breeding and sale of Rabbits. Very extensive farms in different counties have been reclaimed and brought into cultivation, and claiming in many instances the credit of being some of the best farmed land in the kingdom as regards the soil. These sandy

soils are, owing to their position as well as variations of the subsoil, capable of being cropped in various ways, for in those cases where the surface is sharp sand the subsoil is often somewhat stronger, and calculated to support vegetation of a more valuable kind than the poorer soils, which consist of sand, resting also on a subsoil of sand. Again, when sandy land is situated near populous towns the growth of cereals may to some extent be disregarded; particular attention can be given to the production of vegetables, which may be sold as food for the people, or when an over-supply takes place they may be used as food for cattle in the ordinary way. This is one of the privileges or advantages which the farmer has over the market gardener.

As a farming rotation of cropping for sandy land we will again take a farm of 450 acres for illustrating the rotation we recommend. Taking first a farm situated away from towns and in a purely agricultural district, where the object is to keep a large flock of sheep, in order that as full crops of cereals, &c., may be grown as the soil is capable of yielding, our first rotation will apply chiefly to farms in a district where the climate is favourable, such as are frequently found in the eastern, southern, and some midland districts of the kingdom. For sandy land under such circumstances we recommend—in fact, we know of a farm under capital management set out in a seven-course rotation as follows:—1st year, Swedes, Turnips, Mangold, &c.; 2nd year, Barley; 3rd year, Turnips; 4th year, Wheat; 5th year, Clovers and Grass; 6th year, old Clover and Grass lea, Turnips, &c.; 7th, Wheat. Upon setting out the 450 acres in courses we will take 30 acres and lay down 10 acres of Lucerne for permanency, and 20 acres in Giant Saintfoin with Perennial Rye Grass, &c., so that as the Saintfoin after some years may die away the land may be left in permanent pasture. We have, then, 420 acres on which to rest our rotation, and under a seven-course it will give 60 acres as the lain for certain crops; commencing with 60 acres of root crops prepared by autumn fallow, 10 acres sown with Mangolds, 10 acres of White or Red Intermediate Carrots, 20 acres of Swedes, and 10 acres of early Greystone Turnips, to be fed upon the land either as a whole or in part with sheep, or part by bullocks and horses, &c., at the farmstead. This land after being fed off by sheep will be made close and productive by the tread of the animals, and will not only have afforded excellent lying for sheep in the winter and early spring, but will with an allowance of oilcake spent on the land, be as productive for cereal crops as the soil will allow of. The second course will be 60 acres of Barley, which may all be sown early, for nothing but frost and excessive rains can defer the seed time on such land. The third course will be 60 acres of roots, preceded by green crops, Rye, Vetches, and Trifolium, all fed off by sheep in spring, then seeded for early Turnips in succession, to be fed off by sheep in the autumn, which feeding, as a preparation for Wheat, may extend to the first week in December, as this soil will not only carry the stock in any weather, but may also be sown with Wheat in almost any weather except frost. The land after two dressings or foldings by sheep will then be in a fertile state. The fourth course will be Wheat (60 acres), which will be sown in divisions as fast as the roots are cleared off, with such varieties as may be suitable to the time of sowing, the soil, and climate of the farm. Fifth course to be Clover and Grasses, 60 acres. All these will be seeded in the Wheat in the first dry weather in the spring, and harrowed-in with the chain harrow, and rolled with a heavy roller; 30 acres will be seeded with Red Clover, Alsike, and Giant Saintfoin mixed; the other 30 acres to be seeded with Dutch Suckling and Hop Clover as it is called, with Perennial Rye Grass and Italian Rye Grass mixed. The sixth course will be 60 acres of old lea; 30 acres of Clover lea, to be cut twice for hay; the remaining 30 acres to be fed in the spring and ploughed and pressed for Turnips, to be fed off by sheep eating cake, &c. After the Clover

lea has been dunged the whole lain will be in good condition for the seventh course, which will be 60 acres of Wheat, concluding the rotation. In this rotation there will be 120 acres of Wheat and only 60 acres of Barley. The advantage of the Wheat crop over Barley on sand land is that Wheat being winter-sown and well-manured will succeed better Barley, as the spring tillage for the latter in a dry spring or summer makes the crop more hazardous than any winter-sown corn. This rotation or course of cropping is only adapted to outlying districts.

We, however, now must refer to land of the same light description but situated in a favourable climate and near to populous towns, where a large number of consumers will require an extensive supply not only of vegetables but milk and butter. The rotation we advocate will be calculated to supply this demand, and in consequence dairy cows will take the place of sheep for the consumption of vegetable crops, and the cropping with vegetables will be so arranged as to be made available either as food for the people or for cattle under certain circumstances connected with supply and demand. Notwithstanding these are the leading points that relate to the growth of vegetables, the produce of cereal and pulse crops must not be neglected in order that straw, hay as fodder, litter, and corn for meal may be made to some extent supplementary as the food of stock, but also for the purpose of sale when the prices are satisfactory. To illustrate our rotation as recommended we will again take a farm of 450 acres, 50 acres of which may be laid into Lucerne, Saintfoin, and permanent pasture, as alluded to in a former rotation. We shall then have 400 acres to be cropped on the four-course rotation; and still keeping in view the fact of a large number of dairy cows to be provided for, the rotation will be—1st, Wheat; 2nd, green crops and roots; 3rd, Lent corn; 4th, Clover and grasses, pulse and roots. As the root and green crops will be removed from the land and, in fact, nearly all the cereals, pulse, and grass also, the manure at the stalls, stables, and pig pens must be carefully preserved. At the same time purchased manures will be required as back carriage after delivery of all articles sold into towns, except dairy produce, such as milk and butter.

Our rotation may be termed a system of combined farming for corn, dairy, and vegetable produce. The first course will be of Wheat 100 acres, the preparation for which will be better and fully described in the fourth course. We have, therefore, only to observe that none will be sown without the land being in what the farmer calls a correct or advantageous preparation, well manured, either by yard or town dung, or artificial manures. The second course of 100 acres will be prepared immediately after harvest by the autumn fallowing of 40 acres of the foulest land. The seeding of 60 acres of the cleanest land to be as follows:—15 acres of the Giant or St. John's Day Rye, 20 acres of Trifolium of the early and late varieties, 20 acres of the early and late winter Vetches, and followed by root crops seeded in the spring, 20 acres of Mangolds after Rye manured with dung ploughed in, and artificial manures applied by the drill at the time of seeding, 20 acres of Carrots (to follow Trifolium), the White Intermediate being sown first, and the Red Intermediate variety to be drilled last, the seeding of the Carrots to be concluded by the 10th of June. Our practice has always proved most successful when the seed has been drilled at 18 inches between the rows, from the 1st of May up to the 10th of June, as at that time of year the seed will, as a rule, germinate immediately, and very few weeds will appear after a green crop once ploughed, until the young Carrot plants are forward enough to be both horse and hand-hoed. After the Vetches the Hybrid Scotch Green Round will be seeded on the land first cleared, and the remainder to be seeded with the Red Mammoth or Greystone variety of Turnips, drilled after once ploughing. Both the Carrots and Turnips should be drilled with a full dressing of bone superphosphate and Peruvian guano. In referring to the 40 acres autumn fallowed in this course this should be cropped after a good dressing of dung ploughed in, with the earliest sorts of Cabbage, planted in the autumn to the extent of 20 acres, and the remaining 20 acres in the spring; 10 acres should be planted with Champion Drumhead cattle Cabbage, and 10 acres of Early Broccoli. These latter, besides having the dung ploughed in, should have $1\frac{1}{2}$ cwt. of nitrate of soda applied at the first horse-hoeing between the rows. The third course will be 100 acres of Lent corn. Nearly all the root crops will have been removed by the 1st of March, when 50 acres may be sown with early white Oats, Canadian, Lincoln, or Poland varieties being the best, as they will each be ready to harvest before the Wheat; the other 50 acres may be seeded at a later date with White Waterloo or Black Tartarian Oats, and Barley mixed as drege corn. Clover seeds on 50 acres to be seeded in the drege corn, the mixture being Red Clover, Alsike, and foreign seed of Giant Saintfoin. The early Oats we have

sometimes followed with stubble Turnips or in part with the Dwarf Savoy Cabbage planted directly the Oats are cut, a portion being done between the shocks; this may extend to 25 acres, as they will either or both come off in good time to be followed by tall Rape and summer Vetches mixed. The other 25 acres, after the early white Oats, may be tilled and manured for the early varieties of Potatoes or Peas for supplying green to the market in towns; after which, and the haulm harvested carefully, this portion may be sown with early white Pomeranian Turnips, to be pulled off for sale or for feeding cattle. This completes the fourth course in the rotation. Thus it will be seen that all the crops advised may easily be got off in time for the Wheat crop; the Clover having been cut twice for hay or soiling horses, cattle, &c., may be dunged early, and ploughed and pressed early, giving this light soil time to consolidate before drilling the Wheat. The portion of the fourth lain last cleared, such as the white Turnips, Rape, and Vetches, may be dunged, and ploughed, and last sown after the autumn rains have made the land heavy. We shall next refer to gravel and stone brash soil rotations.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—This may still be supplemented by steam power in ploughing and pressing Clover leas, &c., for Wheat seeding, and it is extremely important, because some horses will be required in various work. Drawing out manure will still be going on in some fields in which this work may have been unavoidably delayed. The carting and storing of Mangolds and other root crops must be done, the sooner the better. Swedish Turnips may also be carted and stored at the homestead, near to where they will be required for the feeding of cattle, pigs, &c. Carrots may now be taken up, especially the intermediate sorts, which have short roots and easily removed, and carted away to the farm premises, and placed near to the stables and other sheds, where they will be required for feeding horses and other animals. They are very nutritious for weaned colts, and there is no vegetable equal to them for raising young growing horses into a large size and excellent condition. The Potato crop will require to be ploughed out with the lifting plough. They may then be sorted in the field by women and carted away for various purposes—those tubers touched with disease for the dairy cows and pigs, those for seed stored by themselves, and those for sale stored conveniently for taking to market when required. There is also plenty of work for the odd horse or mule in carting straw to the cattle boxes, stables, and other pens for pigs. Hay, too, will be required for the cart horses, and also Carrots. This must also be done by the odd horse and man, who may and should be specially employed for such work, for we deprecate the plan and practice of the teammen being employed to fetch provender of any kind for the horses under their charge, as it is too often made the excuse, particularly in short days, for reducing the period of labour in the field. Drilling Wheat will be going on; and upon strong land especially, where the weeds usually injure the corn in the spring, it will be necessary to drill at 10 to 12 inches between the rows, as in case the weeds prevail in spring, or when the Wheat plants look yellow and sickly, if the space is not wide enough between the rows effectual horse-hoeing cannot be accomplished. It is no use to expect the work to be done by hand-hoeing. The right season for hoeing is but short, nor is hand-hoeing so effectual for moving the ground as well as killing the weeds as the horse hoe, and when the Wheat plant is unhealthy it will never bring a good-sized ear unless the surface soil is stirred round the plant to give it fresh life and vigour.

Hand Labour.—Some of the men may be employed with the threshing machine, for about this time some Wheat and Barley will be required for sale, and straw for daily use. Drege corn, too, will be required for the horses, and seed Wheat for sowing, as a considerable portion may be grown on the home farm, although we may require to purchase for seed some new variety, newly selected, or pedigree grain. Those crops of roots which like Swedish Turnips may be pitted in the field, or even Mangolds if required for sheep in the spring, may be stored and covered by men assisted by the women; or a man his wife and family may be employed and paid by the acre for the work. Carrots also may be heaped in the field and fetched away by the odd horse or horses as required for use, and this saves horse labour at this busy period of the year. The plan of storing Carrots and Swedes in the field is of the greatest importance, not only because they would be seriously injured by game and rabbits, wood pigeons, &c., during the winter if left in the land during frosty weather, but also because the roots cannot be frozen without losing much of their nutrition. The storing, heaping, or pitting by the acre is a matter of hand labour only, and as such we think it pays well for doing.

On the parklands and pastures in nearly every district Oak trees are found, and as the crop of acorns is this year very great it is frequently found when the cattle are allowed to eat them that they become seriously injured. We have known in some seasons when they have eaten them to excess it has resulted in the death of some of the animals, and of great damage to the health and condition of others. When those which have died and undergone a post-mortem examination, large undigested masses of the acorns have been found

inside the stomach, showing they could not ruminate. We have thought it best to have the acorns picked up by women and children, who receive 1s. 3d. per bushel for the work. They answer a good purpose for feeding breeding sows and store pigs, also for horses in small quantities crushed, because the fruit of the Oak possesses a large amount of flesh-forming and heat-producing properties.

On the heavy Wheat lands, as fast as the drilling or seeding has been completed, the land and water furrows should be struck out with the plough immediately, the men following with spades and shovels to clear them out, with sufficient fall for the water to escape quickly. All kinds and ages of cattle and horses should now receive roots as the days shorten, and come into the yards and courts at night to receive some dry fodder at the same time, unless in a few cases where grass has been specially reserved upon dry land for autumn feeding. Sheep folded on Turnips and Cabbage, &c., should now have hay and also some cake if they are being fed for the butcher; if for stock only a little hay will be sufficient, in addition to the roots, to keep them healthy. The horned Dorset and Somerset ewes just arrived in the home counties appear in good health and condition, except in certain instances where they have been neglected, in which case some flocks have the fluke rot. These have been sold at low prices.

ADVANTAGES OF A HOME FARM.—No. 4.

MANURES FOR ARABLE LAND.

QUITE recently in the *Times* Mr. Lawes published a statement of a series of trials of Wheat grown upon certain plots of land to which different kinds of manure had been applied, and of one plot from which a crop of Wheat had been taken annually for a long time—I think it was thirty or thirty-five years—without having had any manure whatever; but now, he observes, it shows evident signs of exhaustion. What wonderful land must that be at Rothamstead! If I were to attempt to grow Wheat upon the same plot for only a couple of years without manure there would hardly be enough straw and grain the second year to pay for labour. Yet this soil that is so thin and so soon exhausted, in 1878 yielded the extraordinary crop of forty-four bushels of Wheat per acre, and the straw was upwards of 5 feet high! I have still a bunch of it which measures 5 feet 6 inches in length. This crop followed winter Tares, which were used as green food for horses, and the land was cleared in June, and broken up at once for a summer fallow. After the first ploughing, manure of excellent quality from the cow-yard was put upon it at about the same rate as the grass land and ploughed in, and afterwards the land was occasionally stirred and broken up, so that by autumn the manure was mingled with the soil and incorporated with it thoroughly. In October a dressing of quicklime fresh from the kiln was given, the field once more ploughed, and the Wheat sown. The result was so favourable as to raise hopes of similar good results in the following year from another piece of fallow—not, I am sorry to say, to be realised, for the cold stormy dripping summer of 1879 proved very disastrous to the Wheat. The results of such an ungenial season cannot, however, have any bearing upon that of ordinary years, and there can be no question that fallow land, well manured and frequently stirred, yields a crop of Wheat and straw that well repays the extra labour bestowed upon its culture.

Field Potatoes usually follow Oats; the method of culture is simple but efficient. As soon as possible after the corn is carried to the rick-yard, the land, if clean, is ploughed and left for the winter. This year the stubbles were very foul, and the broadshare, horse hoe, and harrows had to be used to clear off the weeds before ploughing. The unusual quantity of weeds is but one of the many lingering traces of the baneful effects of the wet summer of 1879. The stubble weeds showed clearly that much seed had again been shed this year, and therefore after they were cleared off and burnt, the surface was stirred sufficiently with the horse hoe to induce the newly fallen seed to vegetate, which it soon did, so that when the ploughing was done the surface was quite green with seedling weeds, then most easily got rid of by ploughing in, but which without such timely culture might not have sprung up till next year, and then proved very troublesome. In February or early in March farmyard manure is carted and spread upon the ploughed land, and it is immediately ploughed a second time, then left for a week or two till it is sufficiently dry to be thoroughly stirred by a heavy horse hoe of local manufacture, partaking very much of the character of a cultivator, for it stirs the surface soil just as efficiently as a Coleman's cultivator does the subsoil. When by this means and exposure to the air the soil is in a light friable condition, the drills are made with a single-horse plough 30 inches apart, artificial manure scattered along each drill, and the Potatoes planted.

All root crops are exhaustive to the soil, and for this reason an extra quantity of manure is generally used in root culture. It is applied in a variety of ways, for many of which no better reason than local customs can be advanced, yet in outlying country districts such customs are kept to with singular persistence. Mangold Wurtzel, for instance, is generally sown upon a flat-topped ridge, formed by

first ploughing deep drills, which are half filled with manure and then filled with soil by ploughing between them; this leaves sharp ridges, which are then flattened by a light roller, and the seed sown along the middle of each ridge. In wet heavy soils this plan may tend to ensure a good plant, but in light soils it is unnecessary. Spread a liberal dressing of rich farmyard manure upon the surface, plough it in, stir the land well with a cultivator to blend the manure well with it, and make a good seed bed, then sow plenty of seed in drills 2 feet apart, just as you do for Carrots and Turnips, thin the seedlings early, keep down weeds, and stir the soil often between the rows. That this plan is a good one I have clear and striking proof this year in a full crop of such excellent roots of Giant Long Red Mangold, that I had four of them washed and weighed to-day, October 8th. The heaviest root weighed 17½ lbs., and the four roots together weighed 65 lbs., which gives a mean of about 16 lbs. a root, or about 77 tons per acre. The roots weighed were picked, but there are plenty more as large, and the entire crop is so good that the weight would probably be nearly 60 tons per acre.—EDWARD LUCKHURST.

BUTTER MAKING.

JOHN STEWART of Iowa has made a fame as a butter-maker that is not confined to this continent. In 1873-4-5 he took away the highest honours at the great St. Louis fairs; in 1876 he carried off the gold medal at the Centennial Exhibition; he was equally fortunate at the Royal Agricultural Exhibition in London, England, in 1879; in 1878 he took the first premium on October butter, and at the same fair in 1872 he took twelve premiums. Recollect, too, that this butter was made in Iowa.

Mr. Stewart's method in making butter is contained in a pamphlet issued by him in the interest of making good butter. He begins with a treatment of the cow. She must have a warm dry stable, and be fed liberally with ground corn, Oats and Barley mixed in equal parts. He discards the use of Turnips and oil cake, but emphasises the necessity of plenty of good hay and water. He discourages the use of wooden pails, employing tin, which must be thoroughly scalded before using; the receiving can is set in cool water. If a cellar is used for setting the milk he would permit nothing else in it, keep it well whitewashed, and attend to the ventilation. In his opinion milk is injured if chilled too much in cold weather, or if it reaches too high a temperature in warm weather. When the weather is warm he surrounds the pans with water as deep as the milk; milk will keep sweet thirty-six hours at a temperature of 62° to 65°. He does not permit cream to thicken in warm weather before it is taken off; skims sometimes in twenty-four hours, and again at forty-eight hours, according to the condition of the cream; does not keep cream longer than forty-eight hours before churning; churns every day, if possible, at a temperature of 58° to 60° in summer, and 62° to 65° in winter; draws the butter-milk before the butter forms in mass, and washes the butter with clear cold water, or brine, which is better, until the liquid runs clear, then gathers and works it thoroughly, using 1 oz. of salt to 1 lb. of butter; sets it away for twenty-four hours, and works all the milk out, giving a dash of cold water occasionally.

In packing he uses the best quality of tubs, soaking them twenty-four hours before packing; packs closely to sides and bottom, and fills the tub level full; puts on a clean bleached muslin cloth saturated with brine, and a layer of wet salt over that, puts on the cover, fastens with three strips of twine, and the butter is ready for shipment. Butter made in this way always brings a good price.—(*Prairie Farmer.*)

FORTHCOMING POULTRY SHOWS.

CONTINUING our reference to the Shows now pending from page 361, we find that on October 26th opens the great four-days Poultry and Pigeon Show in connection with the Dairy Show at the Agricultural Hall. The entries have already closed, and we have commented on the schedule, but may again call attention to the fact that the classification and prizes for Dorkings are specially good, and so that the show of that useful old English breed is sure to be fine. Farmers who come up to see horned stock and its produce should look at profitable poultry and try to improve their home breed.

For the 27th and 28th—unfortunately two of the Dairy Show days—is fixed the Oxford Show, which is always an excellent one all round. We believe that no Show has done more good locally in drawing attention to poultry breeding, and in converting simply poultry-keepers into careful breeders. In the following week Bath, which used to hold its Show in September, offers a tempting schedule to west-country fanciers, and, indeed, to many others, for Bath is very accessible from many directions. Entries close on

the 18th of this month, and the office of the Society is 42, Milsom Street, Bath. It is long since a show was held in Berkshire, and at last one is promised at Windsor on November 10th and 11th. The schedule is a very fair one for a beginning; the Secretary, Mr. W. Clave, Sheet Street, Windsor. Let us hope that the manager of the Royal poultry yards may be authorised to make some purchases at it. When last we saw that establishment its inmates by no means were such as they might be, or worthy of their fine abode.

The following week is the great Derby week of the poultry fancy, when the Crystal Palace Show is held, to which all fanciers who can leave their homes and occupations flock. The schedule is not in our hands yet, but let us hope that it may be liberal, and that the sums offered in prizes may be in some larger proportion than hitherto to the enormous sums received for entry fees, which last year came up to more than £1400!

The week following the Crystal Palace is that of the Oakham and Tredegar Shows. The former has long been a well-managed and popular agricultural meeting for the midland counties, with good prizes. Great advantages are offered to exhibitors in the way of reduced entry fees who become members of the Society, giving a small annual subscription. The Secretary is Mr. James Wellington, Oakham.

The Tredegar Show will be at Newport, Monmouth, on November 23rd and 24th. The classification and prizes for poultry are good; for Pigeons there are only nine classes. The Secretary is Mr. F. J. Justice, Tredegar Estates Office, Newport, Mon.

On Saturday, November 27th, begins the Birmingham Show, the schedule of which is referred to more fully in another article.—C.

WASHING FOWLS.

FEW things connected with poultry management seem more difficult to accomplish properly than washing fowls. Previous to my having any personal experience in the matter I read articles on the subject, and the more I read the worse I thought it must be to do. Experience has since taught me that washing is a much more simple process than many would imagine, and much that has been written respecting it has magnified the whole affair a great deal more than there is the slightest occasion for. There is no secret in it; the whole is as simple as washing a piece of calico, care only must be observed, and only a fair amount of this is needed. Game and other hard-feathered fowls should not be washed, and it is seldom that black birds of any kind require it unless they are very dirty before being exhibited. Pure white fowls, however, generally want washing before they can be shown, and those of a light colour are usually much improved by washing. Sometimes fowls which should be clean are shown unwashed and dirty, and were I about to buy anything of the kind I should be a little cautious, as it is just possible dirt may be left on to hide defects in colour. Those with fowls of a pure colour are always glad enough to wash them well before showing, as the better they are washed the greater is their chance in the show pen. Buff and White Cochins are about the worst to manage so far as size is concerned; but for particular washing no kind is more difficult to do well than our favourite Sultans with their large crests, muffs under their chin, and so much feather about their legs and feet, all requiring careful handling; but they can be washed easily enough, too, as some of ours, although black and dusty before washing, invariably turn out as white as snow.

In preparing to wash fowls two ordinary-sized tubs should be prepared, one to wash in, the other to rinse them out. Two or three gallons of water should then be placed in a saucepan, adding to every gallon about 1 oz. of white soap, and to the whole a piece of washing soda about the size of a filbert. Boil all together and empty into one of the tubs. Add cold water to lower the temperature to about 110°. The bird must then be taken and placed in the water, sponging it well over so as to wet the feathers, afterwards taking a small handbrush and brush the whole of the feathers down repeatedly. Always brush down with the feathers, not against them. It is easier done when one person holds the bird and another uses the brush. There must be no surface cleaning only—the very foundation must be reached. Do not be afraid to brush hard, it is the only way to render them clean. Sometimes a tail, crest, breast, or wing may want rubbing or brushing for upwards of five minutes before it is thoroughly clean; but clean it must be made, or washing had better not be attempted, as of all the miserable-looking fowls none can be worse than a badly washed one.

In finishing with the brush have a quantity of water in the other tub heated to about 70°, and take the bird out of the soapy water and swill it well in this, as no soap must be left amongst the feathers, or it will make them adhere together. After taking

it out of the water it may be placed on anything clean underfoot, and the feathers gently rubbed downwards with a sponge. This takes much of the water out, but it must be dried thoroughly in a wicker basket before a fire. It should be placed here as soon as it is washed, and not removed until it is dry. When washed in the evening and placed before the fire all night the feathers will be found to be fairly dry in the morning. Fowls should always be washed two or three days before they are sent off to a show. When done only the day before or so some accident may occur, and there is no time to give them another dip. Lately one of our birds was covered with soot blowing down the chimney when he was drying overnight, but we had plenty of time to change his colour again before sending him to the show he was being prepared for.

Some say the feathers ought to be dressed during the time they are drying. I never do anything of the kind, nor find it necessary to do so, as every feather comes into its proper place as it becomes dry. From the time they came out of the tub until they are sent to the shows we dress nothing at the feathers, not even the "fluff" in Cochins, so that this must not be counted in as one of the difficulties to be overcome in washing fowls. After washing they must not be exposed too soon to draughts, or they may catch cold, but ordinary care will always prevent this.—J. MUIR, *Margam*.

THE ALEXANDRA PALACE BIRD SHOW.

THE autumn Show of Canaries and British and Foreign cage birds, which terminated at the Alexandra Palace on the 13th inst., was one of considerable interest to ornithologists and the general public. There were about six hundred entries of birds spread over some seventy classes, and the arrangements made by Mr. F. W. Wilson, who had the management, were such as to afford every facility for careful inspection. The birds in the Canary classes were in such excellence of plumage as to somewhat surprise us, and the honours for the birds in the high-coloured Clear Norwich classes were spiritedly contended for between Messrs. Mackley of Norwich, who gained first prizes in Clear Yellows and Clear Buffs, and Mr. Yallop of Cossey, near Norwich, the latter exhibitor scoring second in each class with very showy birds. Even-marked Norwich, although few in number, were good, and there were many Norwich birds heavily crested, besides two or three fairly moulted London fancies. Lizards were not so good in distinctness of spangles and other qualifications as on former occasions, but the mules of the Goldfinch and Linnet crosses with the Canary were first-class.

Conspicuous amongst the hybrids were those exhibited by Mr. Tom Lovell and Mr. Sleep, the former exhibiting a charming specimen of the Bullfinch and Goldfinch cross, and the latter a bird of the Greenfinch and Goldfinch cross, both of which took prizes. British and migratory birds were (excepting in the Blackbird class) amply represented, and we noticed amid others a Nightingale, Blackcaps, Willow Wrens, &c.

Foreign birds formed not only an imposing portion of the Exhibition, but were remarkable not only as regards the pair of Grass Parakeets, which were of a different plumage than we have ever before witnessed owing to them not possessing that sweetly undulating pencilling so characteristic of the breed, and still more remarkable was the colour, which more approached that of a Canary. The birds were exhibited by Mr. Van der Snickt, and were justly awarded a special first prize. Another noted specimen was an Australian Piping Crow named "Maggie," marked like a Magpie, the playful tricks of which, bursts of laughter and imitations of vocal sounds, "drew down the house."

Considerable attention was devoted to the Widow or Whydah birds, especially that entered by Mr. Bowen, which was very perfect in plumage, general condition, and finely-developed threads in its tail. There were also many fine Parrots, Parakeets, Cockatoos, Weaver Birds, Virginian Nightingales, a Blue Thrush, and others as an auctioneer would remark "far too numerous to particularise." Amongst the principal exhibitors of foreign birds were Mr. W. Satchell, of Hampshire; Mr. J. Drake, of the Aviary, Ipswich; Mr. Bowen, of Kensington; Mr. Groom, of Camden Town; Mr. Barrs, of Derby, &c. The birds were judged by Mr. Harrison Weir (for foreign and British), and Mr. G. J. Barnesby and Mr. E. Bemrose (Canaries and Mules).

[This report was not received in time for insertion last week.]

THE BIRMINGHAM CATTLE AND POULTRY SHOW.

It has for some years been the custom to offer a £10 prize for the best dark Brahma in the Show, and another of the same amount for the best light Brahma. The Poultry Committee have this year decided to give four prizes of £5 instead of two at £10, one going to the cocks and cockerels, and the other to the hens and pullets of each variety.

The prizes for Dorkings remain as before, with the exceptions that the class for "Cuckoo, Blue or any other colour," is withdrawn in consequence of the small number of entries which have hitherto

been made in it; and classes for "any other colour" have been substituted for those for Whites.

The cups in the Cochin classes have been dealt with in the same manner as those for Brahmas, four of £5 being offered, one for Buff cocks or cockerels, one for Partridge cocks or cockerels, one for Buff hens or pullets, and one for Partridge hens or pullets; while one each of the value of £4 are offered between White and Black cocks and cockerels, and between White and Black hens and pullets.

The Langshans, which were shown in great force last year, are divided into four classes instead of two as heretofore, with prizes of £4, £2, £1 10s., and £1 each for cocks, cockerels, hens, and pullets, the second prize in each case being provided by a few breeders.

Instead of there being one class for Andalusians, with prizes for a cock and hen of any age, there are now two classes, with prizes for cocks or cockerels, and for hens or pullets.

The classes for black Game, and also for Piles, have been withdrawn, and these kinds must in future be shown with those coming under the distinction of "any other variety." Messrs. Billing, Son, and Co. continue their prize of £3 3s. for the best Game cock in the show; and Spratt's Patent Food Company offer a prize of £5 5s. for the best Black-breasted Red cock or cockerel; but the prizes which will be most sought after, and which will, doubtless, attract a large number of entries, are two challenge cups, one of the value of £50 for the best Black-breasted Red cockerel, and the other of £30 for the best Black-breasted Red pullet, which are offered by a few fanciers, and which must be won by the same exhibitor three years out of seven before they become his absolute property.

Two cups of the value of £3 each are offered for Black Hamburgs, one for cocks or cockerels, and the other for hens or pullets; and cups of the same value between Golden-pencilled and Silver-pencilled cocks, Golden-spangled and Silver-spangled cocks, Golden-pencilled and Silver-pencilled hens, and Golden-spangled and Silver-spangled hens.

The classes for Game Bantams have been altered. There are now prizes for Black-breasted or other Red cocks, cocks of any other variety, Black-breasted or other Red hens, hens of any other variety; and for cocks and hens of any other variety.

A number of changes have been made in the Pigeon department, the first important one being a class for badge and another for saddle Tumblers, instead of these two varieties having to compete with each other. There are now three classes for Magpies instead of one—viz., for Blacks, Reds, and any other colour; four instead of two for Jacobins, for Blacks, Reds, Yellows, and any other colour; and three instead of two for Turbits, for Red or Yellow, Blue or Silver, and any other colour. The class for Blue Chequered cock Dragoons, and also that for Red or Yellow Dragoons, have been withdrawn, so that in future these varieties must compete with those of "any other colour." The prizes for Antwerps have been increased, an additional one of £1 10s. being offered for Silver Duns of any age, one of £1 10s. and another of 10s. for Silver Dun hens, and one of £1 for the best Red Chequered bred in 1880.

Several minor alterations will be seen in the prize lists, which, together with certificates of entry, may be had from Mr. J. B. Lythall, Bingley Hall, Birmingham. The entries close on Monday the 1st of November, but post entries can be made in this department up to the following Saturday upon payment of double fees.

The following gentlemen have consented to act as Judges:—*Poultry*—Mr. James Dixon, Mr. Leno, Mr. W. R. Lane, Mr. J. H. Smith, and Mr. R. Teebay. *Pigeons*—Mr. T. J. Charlton, Mr. H. Child, and Mr. F. Esquilant.—(*Midland Counties Herald*.)

VARIETIES.

HIGHLAND CATTLE.—An agricultural writer observes that the West Highland breed has occupied a district in the Highlands of Scotland anterior to the records of history and tradition, and have acquired characters suited to a country of heaths and mountains. These have been produced in the highest state of perfection in Argyleshire and the adjoining islands. The cows, like all mountainous breeds, give but a small quantity of milk, but of a superior quality. These cattle are best and most profitable when fattened at an early age. They will live and thrive on the coarsest pastures, and when turned upon good pastures they will gain a third of their original weight in six months. They lay their flesh and fat on the best parts, and when fat their beef is fine in the grain, highly flavoured, and so well mixed or mottled that it commands the highest price in every market. This breed is, in fact, strictly a beef animal and nothing more.

— **AMERICAN WHEAT FOR ENGLAND.**—The American papers remark that the Royal Agricultural Commissioners, Messrs. Reed and Pell, have made a mistake in estimating the average yield of Wheat in America at 13 bushels per acre, and observe that from the districts that are likely to compete with England, the averages are much higher, —namely, over 20 bushels. The *Cultivator* observes that American Wheat is produced at an average cost, all over the United States, of 20s. per quarter, or 62½ cents per bushel; allowing 10s. per quarter for cost of transit to Liverpool (and this is a liberal allowance), it concludes that American producers have the advantage of quite a margin of profit, equal to about 42 cents. per bushel. Independent of all statements, however, grain can be taken from Chicago to Liverpool for 22 cents a bushel at a profit. Therefore American Wheat can be sold in Liverpool in enormous quantities at \$1.20 per bushel with a profit to the producers, carriers, and dealers.

— **DESTRUCTIVE SNOWSTORM.**—A recent telegram from Lisbon states a terrific snowstorm occurred in the province of Buenos Ayres on the 18th inst., in which 700,000 cows, 500,000 sheep, and 250,000 horses are estimated to have perished. The storm raged with more or less violence during three days and three nights, and was the greatest ever known there.

— **AGRICULTURAL PROSPECTS.**—The fine weather of the past week has made farmers too busy to write reports, and our advices this week are therefore fewer than usual. The ground turns up exceedingly well, and Wheat-sowing is going on very favourably. Mangolds are now being lifted, and if the weather keeps dry a very useful crop will be got together. It must be borne in mind, however, that the lateness of the season has prevented Mangold from maturing in all the colder soils, and a large proportion of the crop is not now any nearer maturity than it usually is at the middle of September. If growth has ceased the sooner they are up the better; if not, and if time present is considered safer than time to come, they will require a longer time than usual to ripen in the pit or stock. Swedes are mildewed in places, but on the whole are an excellent crop. The early frosts have touched the leaves of the common Turnips, but there is no damage done yet, and root crops, Cabbages, and Kohl Rabi will turn off an unusual amount of keep this season. The trade for store cattle has brightened a little, and but very little, the scarcity of cash being far greater than that of keep.—(*Mark Lane Express*.)

— **THE ELECTRIC LIGHT AND INSECTS.**—A suggestion was made at a recent exhibition of agriculture and insectology at Paris, that the electric light would form an excellent trap for moths and other night-flying insects. That the suggestion was a good one is proved by the fact that some electric lights on the Boulevards which were near coffee stalls have been extinguished, for they attracted a perfect plague of moths and other insects, which fell in shoals on the shoulders of the customers, and into their cups. A similar result, says a daily contemporary, was experienced recently at Charing Cross—an electric light on a roof attracting innumerable flies and moths, some of them no doubt from considerable distances, as they are rarely seen near town. Enterprising entomologists may take a hint from these facts.

— **THE HONEY HARVEST.**—The crop of honey throughout the home counties is, we understand, very abundant this year. Small farmers and cottagers in many districts have begun to study the subject of bee-keeping, and are introducing improvements in the construction of the hives, which have proved successful even beyond their most sanguine expectations. We have heard of some swarms producing over 100 lbs. of the popular sweet this season, which is a handsome return for the outlay required. The large imports of comb honey coming from America this year is an indication that the industrious bees have had a good time of it. Honey from "over the water," in small combs, is just now selling in Glasgow at something under 6d. per lb., and will no doubt command a large and ready sale through the medium of the family grocers and confectioners, as it is much sought after in the winter months as a curative and preventive of colds as well as a popular adjunct to the tea-table.—(*Grocer*.)

— **THE AMERICAN AND CANADIAN FOOD SUPPLY.**—There was a large increase in the number of live stock and the quantity of fresh

meat landed at Liverpool last week from the United States and Canada. The total arrivals were 2738 cattle, 1223 sheep, 1072 pigs, 5798 quarters of beef, 355 carcasses of mutton, and 125 dead pigs.

THE ROUTINE OF BEE MANAGEMENT.

FEEDING bees at some seasons has of late years been necessary and important. Those who have attended properly to this work have been the most successful and have had but few, if any, losses by death from starvation. If any of the readers of the Journal have not given their bees enough to keep them till March, we advise them to do so as soon as possible. Autumn feeding in my opinion should be completed in September for more than one reason. The quieter bees are after September ends the better. The quieter they are the less honey they consume. Feeding excites bees to fly abroad, and in doing so many hives may be lost during cold or inclement weather, and feeding often excites the bees to set eggs widely in mild autumn weather. Cold weather may come and cause the bees to draw themselves within the lines or limits of their brood, and thus leave it to be chilled to death. Foul brood results, and ultimately the ruin of the bees, from feeding at untimely seasons. Hives this autumn are, generally speaking, strong in bees, which have during the last few weeks consumed much of their winter stores. In mild winters and open weather the bees in very strong hives require oreat from 12 to 15 lbs. of stores from the middle of September till the middle of March. The bees of small and weak hives will not consume half so much. Feeding now should be completed speedily, for slow continuous feeding may cause the evils which have been indicated above. While autumnal feeding is going on the doors of hives should be contracted, in order to prevent robber bees from entering and extracting the honey.

After feeding has been completed, the boards of hives should be well cleaned. The wax moth, next to foul brood, is a destructive pest in apiaries. It has been said that Langstroth recommended wooden hives because the wax moth could find no resting place in them; but it is now well known that the wax moth is no respecter of hives, and breeds as fast in wooden as in straw hives. The scales of wax that drop on the boards of hives are gathered together and form nests for the maggots of the moth. If either earthenware or iron vessels used for feeding purposes be left for a short time on the centres of the floor boards, young moths will soon be found beneath them as well as round the edges of the hives. The maggots of the moth feed on their nests—viz., the fallen or lost scales of wax, till they are able to crawl to and lay hold of the combs of the hives. Amongst the combs the maggots make sad havoc, for they live upon pure wax and consume much of it. Unfortunately the bees tolerate and permit the presence of the wax moth in their hives, and seem not to know that it is a destructive enemy living on their produce. Hives in summer should be often lifted off the boards, in order to destroy all the maggots of the moth before they are able to go amongst the combs. At the present season all the floorboards of hives should be well scraped and cleaned; and if at all wet from rain or the absorbed moisture of the hives it is important that they should be well dried.

Covering hives well and warmly for the winter months is the finishing work of the apiary, and though last in time is not least in importance. My preaching on this point is better than my practice, for my hives are never sufficiently covered in winter and spring. A quantity of material of some kind is necessary to cover sixty large hives. Bees are tiny fragile creatures and require attention in cold weather. Both cold and wet are hurtful to them. Hives should have good warm under-coverings, and their outer coverings should be waterproof. Not a drop of rain should be allowed to touch either hives or boards after September, for if either hives or boards are damp in winter frost may convert the moisture into ice. Hives in bee houses are easily kept dry and warm in winter, and hence my prejudices against bee houses grow less and less. The protection of a good warm covering should be given to hives either with or without bee houses, and such covering should not be removed altogether from hives till the end of April. In recommending warm covering for hives in winter, I once unwisely said that a woolly sheepskin turned inside out would be a model cover for a bee hive in winter. In doing so my aim was to convey the idea of warmth, though I knew that the leather of the skin, or the skin itself, would prevent the moisture of the hive from escaping. And this seeming blunder of mine was pointed out by an advanced bee-keeper. All covers of hives should be porous enough to let the moisture of hives pass through; otherwise it would be condensed, keep the hives damp, and do harm. Warmth, dryness, and ventilation should all be considered in covering hives for winter and spring.—A. PETTIGREW.

OUR LETTER BOX.

Keeping Fowls—Leg Weakness (*J. W. S.*).—Your questions cover a great deal of ground, and to answer them all fully would be to write a small treatise on poultry. The crosses which you have are very bad. First crosses are for certain purposes good, but to cross crossbred fowls again with others crossbred is a bad plan. Your stock, too, is evidently of a delicate strain, and we advise you entirely to get rid of it, except the Game cock and Brahma hens. In the place of your other hens you might well obtain some strong Dorking pullets. The first cross from these and the Game cock should be excellent for all purposes. The situation of your poultry house and run appears very good, but we often find that birds reared on very rank herbage seem to lack stamina, and are often weak in the legs. Put plenty of grit and mortar rubbish about their place. The staggering probably indicates liver complaint, which is incurable, and the sneezing general weakness. Your stock being what it is we do not think it worth a long system of physic. Before, however, introducing fresh birds disinfect the house thoroughly, and lime the grass about it thickly.

Feeding Poultry (*Mrs. Lucas*).—Our theory has always been the same, and it has stood the test of many years of breeding. It is during the period of growth to feed as well as possible, in order to supply the means of increase. Although in most instances pullets cease to grow when they begin to lay; but the furnishing of plumage and the filling-out of frame then begins, and although growth ceases there is a constant increase of weight. Many amateurs consider spare feeding that which we should call luxurious. Scantily fed chickens cannot make large hens.

Fowls not Laying (*F. T. Berks*).—Hens will not regularly lay in the winter; only pullets can be depended upon to do so. You should therefore keep some early pullets every year to provide you with eggs in the winter. As a rule fowls do not like Oats. You must feed differently. Have your Oats ground fine—so fine that the meal will make dough, like flour. You must take nothing from it, but grind husk and all. Give them some whole Barley for a change, and once a week a few boiled Potatoes.

REMARKS.

10th.—Rain more or less all day.
11th.—Very fine morning, with bright sunshine; afternoon cloudy, heavy shower 4 P.M.; fine evening.
12th.—Fine bright morning; rain at noon till 3 P.M., fine afterwards, and cold.
13th.—Fine, bright, and cool.
14th.—Overcast first part of morning; fine with bright sunshine after 11 A.M.; fog in evening.
15th.—Foggy morning; cold overcast day.
16th.—Early morning fine; slight rain in forenoon; afternoon and evening fine but dull.
A bright week on the whole, but foggy at times on the last two days. Temperature rather below the average.—G. J. SYMONS.

COVENT GARDEN MARKET.—OCTOBER 20.

PEACHES and Pines have been in request during the past week, and prices have considerably improved. Best samples of Grapes have also realised better prices, but business has been generally quiet. American Apples are now reaching us in large quantities, and making their full value.

MAKING AND FURNISHING AN OLD-FASHIONED FLOWER BORDER.

THE reaction which set in a few years ago in favour of old-fashioned border flowers has lately gathered much strength and is quite likely, in many gardens where sufficient thought may not be given to the subject, to be carried to extreme lengths, so that "bedding-out" may fairly be expected to crop up in a new form in the shape of these hardy flowers. For small gardens these, supplemented with some of the finer hardy florists' flowers, may well be left to hold their own against the ordinary bedding plants as usually managed, always provided the selection and arrangement of the plants are correct. Pelargoniums and Calceolarias have obtained a hold in many country gardens that it will be difficult to displace, nor is there any necessity for it. A lady of high rank expressed her opinion to me the other day that far too few of these were grown now-a-days. Certainly there is nothing to approach them for autumn effect when planted *en masse* with a large expanse of grass as a setting; yet for these, fine-foliaged plants, hardy florists' flowers, and the commoner hardy border plants, there is plenty of room and to spare in the larger class of gardens.

Especially grateful must those gentlemen be who have had their periodical fit of grumbling at their predecessors who removed the old occupants of borders to the rubbish heap, that they can again fill these same borders with the same kind of plants without running counter to that bedding fashion which does so much to break the backs of so many of us poor gardeners. It is to such borders I wish these remarks to apply. Bedding plants are entirely out of place, as a rule, in the positions the borders occupy—the kitchen garden, and even the poorest attempt at arrangement we have seen in these borders has been redeemed from failure by the interest the individual plants call forth; but now that effect in planting has been thoroughly mastered, and our employers have been accustomed to this effect for so many years, we must not suppose that they will tolerate any return to a system where effect does not hold a place of first importance. We can safely claim for mixed borders effect quite as good as can be procured from any other style of arrangement. Ordinary bedding plants, mixed anyhow so long as height is considered, make a border of great beauty—so great that only those who have seen them can realise what can be made out of odds and ends otherwise of no value; and so a border of well-selected

herbaceous plants supplemented with florists' flowers produce a display that cannot easily be excelled. Such borders as these have always been favourites of mine from their great value as cut flower depôts. From February or March into November we can always rely on obtaining a quantity of cut flowers from these mixed borders—flowers, too, that are always welcome, more especially in the spring months.

In commencing the formation of a border for hardy flowers a thorough preparation of the ground is of the first importance. I had occasion to make such a border seven years ago; and as the soil was of the poorest character, and had apparently never been cultivated more than a spade's depth, I cleared the worst of the subsoil out, and added a foot in depth of fresh material from an old rubbish heap, thus securing a good border about 30 inches in depth; as a reward for my labour I saw some Delphiniums in that border last summer averaging 9 to 10 feet in height. I also made and planted two borders five years ago, but had much better soil to work on, so that nothing but an ample dressing of dung was given, the borders being trenched three spits deep. With two surface dressings during that time all kinds of hardy plants have succeeded well. This autumn the borders have been emptied, and will again be trenched and a good dressing of manure worked in, when they will be expected to keep the plants in good flowering condition for a few years.

Though these borders have been under crop for five years, I would have preferred having them trenched again at the end of the third year. That is quite long enough for the majority of herbaceous plants to remain in the same position without being divided and replanted in freshened ground. As I was guided in the two cases just cited by the nature of the soil, so I advise others to be. In a poor unworked soil it is hopeless to expect the strong-growing species to do well, but provide them with a deep and good soil and they will flourish. In most gardens there are heaps of rubbish lying waste which can be made very good use of in improving the flower borders. If the soil is already in good condition I do not think it necessary to do more than trench deeply and work in a heavy dressing of manure, or manure and soil, as the work proceeds. This should be done immediately. It is also important that the plants be obtained at once. Many bulbs require planting without any delay if they are to be of much use for next year's display. Other plants should either be purchased or procured from friends at the earliest moment. A few years ago plants were to be had which could be divided at this time into, in some cases, a dozen pieces, which with a little kindness in the intervening period would have formed good plants by the following March; but nurserymen now divide the plants themselves, so that sometimes it is necessary to exercise much care to have the single plants sufficiently strong by planting-out time. In spring, when the bulbous plants have all made an appearance above ground, a further dressing of half-decayed manure should be forked-in about 6 inches in depth, and placing in it the remainder of the plants which are quite hardy, those that are tender to follow.

Different styles of arrangement are advocated. I prefer the mixed system, and will explain more about it presently. First, there is the formal laying-out of the borders in "parterres," employing large quantities of a very few kinds of plants to give effect; secondly, grouping the species together instead of scattering them about the borders; and thirdly, planting

very thickly and leaving the plants to support each other, or what would probably most likely occur, to kill each other. The latter mode may well be called the "self-supporting" system. There are also advocates of a system of carpeting the ground with dwarf growers, and as I understand it, planting larger plants thinly amongst them. A bit of mother earth or the shadow of a stake or tie are not to be tolerated as partaking of artificiality! However, everyone to his taste.

In planting an "herbaceous" border, the time when the greatest show of bloom is wanted must be always taken into account. We have borders here planted for late autumn display, in which Dahlias, Tritomas, and Sedum speciosum play the principal part; other borders are for spring and autumn display combined, and others again for general effect, and are in the best condition from the end of May to the middle of July. Again, the width of the borders must be taken into consideration. In narrow borders tall rank-growing plants would require to be kept out, and only those admitted which would make incongruity impossible. Six feet wide is about as narrow as a flower border ought to be made to produce a good effect. A width of 10 or 12 feet allows for the greatest amount of variety in time of flowering and kind of flowers that need be grown. Such a border as the latter may be divided from the vegetable quarters by espalier fruit trees, or an evergreen hedge of Yew 6 feet in height, or by a row of Sweet Peas. In any case a narrow alley is required between the divisional fence and the remainder of the border. The edging to the border may be of Box, but where this does not do well the common Gentianella, Thrift, or Daisies may be used. Festuca glauca or F. viridis, Sempervivum californicum or Saxifraga pulchella, are also useful for this purpose.

In arranging the plants for any particular season select a few of the most reliable species for the various lines to give effect at that period, filling-in the remainder with plants to bloom either at a different season or to supplement those which give character to the border. For an all-the-year-round border the main portion at the back may be left to produce the principal autumn display, having, of course, a due quantity of dwarf-growing species to give colour to the foreground as well. For a spring display the foreground must be mainly utilised for this purpose, but Crocuses, Snowdrops, Sisyrinchium grandiflorum, early-flowering Narcissi, Iris reticulata, Primroses, Aubrietias, Hepaticas, and similar plants may be freely mixed amongst the taller-growing autumn and summer-flowering plants. During the earlier summer months there is no difficulty in having the border as gay as you please; a wise selection will be the most difficult business in arranging for this season. The plants admissible to the front row should not range over 9 inches in height; graceful species, of which Sieversia triflora may be taken as a type, may, however, be admitted. Again, in the second row none lower than 9 inches in height should be admitted, and Pinks, dwarf Carnations and Picotees may be kept as the highest. Such plants as Gladioli, Sunflowers, Foxgloves, Lilies, and others of a like habit may be planted with those which are 18 inches or 2 feet lower. Such a graceful hardy plant as Euphorbia Lathyrus, hardy grasses, and any other graceful-foliage plants may also be used on the same style of arranging amongst much dwarf-growing flowering plants. I strongly recommend also the addition of such florists' flowers as the free-growing self Pansies, Alpine Auriculas, Pinks, Pyrethrums, Mimuluses, Sweet Williams, Gladioli, Roses, Dahlias, Phloxes, Pentstemons, Antirrhinums, double Potentillas, Delphiniums, and Hollyhocks. Plants which take a time to make large clumps or masses, such as Pinks, Auriculas, and many others, also Gladioli, should be planted in groups of at least five of each variety.

Much discretion is needed in staking and tying the plants. Lilies, Lupinus polyphyllus, and others of strong habit do not require staking. Plants of the habit of the Pyrethrum look all the better without stakes too, but the great majority of the stronger-growing species require supporting; this, however, is an art which I have no doubt will be better understood before long. It is necessary that all plants requiring supports should have them at an early stage. Another item of the utmost importance is to remove all decaying flowers, and to keep wide-

spreading dwarf plants within bounds by pulling away the parts which commence encroaching on their neighbours' territory.—R. P. BROTHERSTON.

ABNORMAL GROWTH IN THE GRAPE VINE.

IN the course of Mr. Taylor's instructive remarks on "Keeping Grapes," page 365, allusion was made to the fact "that it is immaterial which end of the Vine shoot, with bunch attached, is inserted in the water." I do not remember seeing this advocated before, and it appears to have been only recently discovered by Mr. Taylor; at the same time it has long been known and practised by a gardener under whom I served some years ago. It is very important in the successful keeping of Grapes that not only should the bunches be freely thinned out, but that also when bottled they may hang clear of the bottles. With the Black Alicante especially this is sometimes impossible, or managed with difficulty, on account of its short-jointed growth. Whenever this was found to be the case, either with this or any other variety, we obviated the difficulty by inserting the points of the shoots (in the first instance, I believe, haphazard, and with the intention of using those bunches first), and so well did they keep that since that time I have never been very particular which end was inserted. Mr. Taylor commenced this practice on hearing that Mr. Wildsmith at Heckfield "had caused one of his Vines to grow the reverse way by pegging the top down, and when rooted to cut off its end which had the original roots." Now this accomplishment of Mr. Wildsmith's is another proof that if the old saying, "There is nothing new under the sun," is not right in the abstract, it in many ways frequently receives remarkable confirmation. Whether Mr. Wildsmith does or does not regard his experiment as original I have no knowledge; but I well remember during the early part of my gardening career being much interested in a plan adopted by an ordinary jobbing gardener, to strengthen a very fine well-trained specimen of the common Sweetwater. It was planted near the end of one of a row of connected villas, and was gradually allowed to extend over the front of two others. The main stem was taken along just over the lower windows, and from this at intervals were taken up fruiting rods. From near the centre of the main stem a rod was gradually taken along the under side, and this, when of good strength and well ripened, was brought down and firmly pegged into a heap of fresh soil. It readily emitted roots and swelled rapidly, and when I last saw it (about ten years ago) was bidding fair to attain to the dimensions of the original stem, and was doing its part towards supporting the Vine. The operator was certainly a fairly intelligent man, but his ideas were not original, the practice being merely a repetition of what had been done with a Vine many years before by an old Scotchman.

I might adduce other proofs in support of my argument; for instance, those who have layered Vines in pots may have observed that roots are as freely emitted beyond as they are below the bud or shoot, all alike, when the rods are separated, swelling, spreading, and equally supporting the young Vines. The same thing occurs when the Vines are propagated from "eyes." Neither is the Grape Vine singular in these respects, for I believe the same results would follow the layering or the striking of the points of any free-rooting trees, notably the common Willow, and the inarching of those kinds that do not strike freely, provided the buds were removed from the tips of the shoots.

Mr. Taylor will please to understand that I do not one moment assume superiority, but am writing with the motive of bringing forward a subject which probably but few have ever thought but little of. It is a discovery which both Mr. Taylor and other men may put to a practical use, as offering a good and simple means for the renovation of old Vines.—W. IGGULDEN.

NERIUM OLEANDER ELEGANS.

I WISH to recommend this handsome free-flowering plant, as it is so useful for decorative purposes at this time of the year. The usual time of flowering is much earlier, but I have now some fine specimens with large numbers of flower buds about to expand. This desirable result I attained by cutting down the principal flower stems—which never flower a second time—and placing the plants in an open border until a fortnight since, when I lifted and potted them and brought them indoors. If this lifting be done carefully I have found no check result, otherwise the flower buds drop off. To avoid this, plunge the plant outside in late spring or summer in a pot which the roots will only be likely to fill; if too large you might have foliage but no flowers, and the lifting will not interfere with the subsequent flowering in autumn. It is always best to have a stock of young plants coming on, propagation

is therefore important. Ripened cuttings or side shoots plunged in soft rain water, with a piece of charcoal at the bottom of the bottle, I have found to be the quickest method of increase. The cuttings root into the water in three weeks, and should be potted at first into comparatively small pots, being careful not to press the potting material too hard. Their great pest is white scale, but I have found no trouble in keeping it under by occasionally sponging the leaves with a solution of carbolic soap; even without any scale this would be desirable as a cleansing process for that as well as all fleshy leaves. I saw in July in the conservatory at Glenview a specimen with hundreds of flowers.—W. J. M., *Clonmel*.

THE POTATO DISEASE.

My last paper concluded with the promise of some cultural directions which I have found effectual in mitigating the severity of the disease. They will perhaps be more useful if I am permitted to call attention to the process of growth of the tuber. The set is planted in the soil, and produces a young plant which grows rapidly both in the soil and in the air above it. Briefly, the part in the soil has to gather and carry liquid food to the part above the soil. This part in its turn conveys this sap to the leaves to be acted on by the sun and air. It is then returned to the tubers in the soil. What I want to be grasped very firmly by my readers is the frailty of the mechanism by which this process is carried on. What myriads of delicate organs are performing this work! and this has to be carried on sometimes when the soil is extremely wet, the foliage beaten to the ground by wind and rain, and the air laden with vapour. The consequence is the whole plant is gorged, with little or no chance of disposing of the moisture. Is it, then, surprising that some of these organs give way, are burst, and disease begins?

Now in growing Potatoes subject to trying times, our efforts should aim at helping them over such a crisis in their lives. This can be done by proper planting and good drainage, and by giving room for the sun and air to play around the soil near the roots and through and around the foliage to dispose of the excessive wet by gravity or evaporation. In these general directions the object is to relieve the roots and foliage from excess of moisture.

To dispose of the rain by gravity, see that your land is well drained, trenched, ridged, or deeply dug, that all excessive wet may soon sink away from the roots. If the land slopes always plant with, not across the slope. If compelled to plant in flat stiff soil, throw your land into narrow beds with good trenches on each side, and let your rows run from trench to trench, put your sets in shallow, and earth up slightly.

To secure effective evaporation and get rid of the excessive moisture in the foliage, plant wide both ways—that is, from 2 to 3 feet between the rows, and from 1 to 2 feet in the rows. Here you must consider the quality of the soil and the variety of Potato. There must be no overcrowding nor waste room, but there must be room for thorough ventilation and the sun's rays to reach the soil and roots of every plant. Of seed I would simply say, Secure that which best suits your land, and if possible have it from an inferior climate to your own. It seems hardly necessary to write more particularly to practical men, and its importance will perhaps be more evident upon reflection. I should like to say that writers on the Potato do not appear to notice sufficiently the effect of the foliage on the disease. The high-class Potatoes generally have a much smaller evaporating surface than the coarser varieties. They cannot even bear up their own weight without resting on the ground, while such varieties as the Champion stand erect, and allow the sun and air to play all through the foliage and down to the soil as well. Mr. Lee of Clevedon evidently sees the benefit of this, but does not recognise the cause.

In leaving this subject I should like also to call attention to the following facts, and ask the advocates of the fungus theory to harmonise them with their views. The outside roots of a row and the outside rows of a patch or field always give a larger proportion of sound tubers than the inside rows. The row of Potatoes grown over a rubble drain gave sound tubers when the adjoining rows were nearly all diseased. The row grown on the sheltered side of a line of Scarlet Runners from the south-west rains were dug perfectly sound from a nearly dry soil, while all the rest were badly diseased. Roots grown close to a coarse-growing weed, such as "Fat Hen," invariably give sounder tubers than other roots in the same patch. These are some of the experiences of—
AN INTERLOPER.

PAULOWNIA IMPERIALIS.—I send a leaf of the Paulownia imperialis. I have never seen, in any account of this tree, any notice of the strong smell of opium throughout the whole of it.

This was evident to me on first examining my plant, and it seems worthy of notice. The fresh bark of trees 20 feet high, as well as the succulent stem of those of a foot only, all possess the same quality. This may be of interest to chemists who are not acquainted with the Paulownia.—M. G. S.

FALLING LEAVES AND RUINED CHOIRS.

I NEVER remember the fall of the leaf to have been more swift and sudden. The last two or three days were bright, warm, and calm. The night before last (October 20th) showed 12° of frost; and though the air continued quite still, about 9 A.M. next morning armies of leaves began to move and slip silently to the ground, and in less than an hour most of the trees, notably the Limes and Chestnuts, in our garden and surroundings were all but bare, and the distances were open to the sky which showed coldly blue, and was being rapidly traversed by masses of suspicious woolly-like clouds. The scent of snow was not far off. About 4 P.M. a few drops of rain fell, changing into a sleety shower, and then for a few moments there was a good fall of large snowflakes—unmistakeable tokens from the wings of winter. More rain and sleet fell in the night. Now (noon, October 21st) the temperature is clear and cold, not unsettled so much as seasonable.

"When yellow leaves, or none, or few, do hang
Upon those boughs which shake against the cold,
Bare ruined choirs, where late the sweet birds sang."

With us at least the sweet birds did something besides sing. The blackbirds held high banquet in the boughs of the Cherry trees, making no mistake in the successions from early Kentish to late Morello. Their audacity and the audacity of smaller birds is more irrepressible than ever. In a graceful poem under the well-known initials "W. W. S.," in "Blackwood's Magazine" (August), the blackbird is credited with a black bill:—

"His are the sunny sides that through and through
He stabs with his black bill."

Shakespeare in "Midsummer Night's Dream" has—

"The woosel-cock so black of hue
With orange-tawny bill."

And Tennyson in "The Blackbird"—

"A golden bill! the silver tongue."

My observation inclines to the yellow bill. Is it always yellow? Would it be too much to ask the favour of an opinion from one of the learned contributors to the Journal? Does the age of the bird affect the colour of the bill? Can our English poets and a distinguished American all three be right?—A. M. B., *Mid Lincoln*.

LAWN MOWERS.

WE note under this heading in your last issue on page 374 that Mr. R. Inglis attaches great importance to the practice of leaving the cut grass on the lawn, maintaining that by thus keeping up the fertility he keeps down the Daisies; but he says he collects the grass round flower beds and the edges of the lawn, so that we should like to know whether there is not a well-defined border of the "wee, modest, crimson-tipped flower," or whether the fertility of these places is kept up by the application of lawn manure, or in any other way. If there is really an advantage in the practice, there is surely some decided difference in the appearance of the two differently treated parts, which, however, Mr. Inglis fails to record.

Our experience of leaving the cut grass on the lawn as in most subjects of a like nature, is that the same rule does not hold good in all cases. Where the growth is not very luxuriant, and mowing is well attended to, the practice may be followed, but where there is a vigorous growth it is not to be recommended. We have known instances where sweeping and handpicking have been resorted to in order to remove the dead grass, which was accumulating in sufficient quantity to give a brown appearance to the lawn. The application of a little lawn manure in the spring will keep up the vigour of the grass, and the cut grass may be economically used by digging it in for any other crop.—JAMES CARTER & Co.

THE ROSE ELECTION.

TEAS AND NOISETTES.

I NOW proceed to give the result of the voting for twenty-four varieties. In this, of course, the columns are the same as on page 345. I have only added an additional column showing the position of each Rose in the election of thirty-six varieties, so that it is easy for anyone interested to see the variation of

opinion. It will be noticed that Rubens and Alba Rosea hold exactly the same position; practically Jean Pernet, Madam Welsh, Moiré, and Madame de St. Joseph also do so. Much in the table, however, speaks for itself.

In this twenty-four varieties election the first column denotes the best six (not twelve), the second the next best six, and the third the next twelve.

Ten more Roses polled four votes, five were named three times, twelve obtained notice only twice; and twenty-three, a fourth of the whole number named (ninety-four), had but a solitary vote.

Will not this tabular statement surprise many? It is not that in naming twenty-four varieties or thirty-six varieties, there is any such marked difference in the first three dozen, for were a beginner to order the first three dozen from either list there would only be a difference in four; but it is the surprising difference in the number of votes polled after about a dozen have been named. For instance, with twenty-eight voters in the thirty-six varieties, we do not arrive at a Rose polling only half the "highest possible" till we arrive at No. 29, Bouquet d'Or; whereas in the twenty-four varieties with forty-one voters it is reached as early as No. 25, and then with a drop of two below. Indeed the rapid falling-off of the number of votes after two dozen have been named, although the voters are so much more numerous, appears to me fully to bear out the remarks of one of our greatest rosarians in the trade when he says at the end of his list, naming two or three additional, these "would about exhaust the number of Teas." Truly in this comparison of the greater and smaller number of varieties it is quality that tells. Judged by the test of quality—that is, first-class votes, Maréchal Niel must have been a long way at the head; indeed no other Rose would have been near, dear old Gloire following at a respectable distance. There is, in fact, a "soft place," a weak point in the Teas, and it is, I apprehend, setting aside the delicacy, the matter of "stuff." Here, as I ventured in one of the earlier elections to say, is the blot on their escutcheon. Either this valuable quality is deficient, so that many of the varieties are thin, or there is so much of the article that a dampness in the weather or any slight blemish seals up the bud and it refuses to unfold its charms. Such Roses,

for instance, as Isabella Grey, America, and Marie Guillot are extremely disappointing in this way, and it is in this that I think Catherine Mermet excels, that though very full, she rarely refuses to open—at least that is my experience.

As I thought it would interest many of our readers to see the American opinion of the class, I sent a voting paper to our kind friend Mr. Ellwanger, in New York. It will be recollected that his list of two years ago in the general election was noticeable for the very strong aroma of Tea that pervaded it, which made me suspect that the climate was better adapted to their growth than our own, and I now append his list:—

Position in 24 vars.		Position in 36 vars.	
1.	Maréchal Niel	No. 2	No. 8
2.	Catherine Mermet	" 3	" 1
3.	Marie V. Houtte	" 4	" 5
4.	Jean Ducher	" 19	" 12
5.	Madame Bravy	" 28	" 34
6.	Bougère	four votes	" 48, 9
7.	Rubens	No. 10	" 10
8.	Marie Berton	not named	one vote
9.	Comtesse Riza du Parc	only two votes	No. 47

It thus will be seen that in naming twenty-four varieties Mr. Ellwanger names several that are not considered in any degree deserving with us.

The names of those who have assisted in the election of twenty-four varieties, and to whom all, but most especially the returning officer, are deeply indebted, include, of course, all those whose names appeared in last week's issue as assisting in the thirty-six varieties, and the following additional amateurs:—Revs. Alan Cheales, J. H. Fuller, J. A. Williams, and E. L. Fellowes; Messrs. E. R. Whitwell, Henry Poulter, Wm. Walters, W. H. Wakeley, and J. Tranter; and of nurserymen—Messrs. B. R. Cant, H. Frettingham, Jefferies & Son, and Mitchell & Sons, making with the twenty-eight named last week forty-one voters in all.

I have selected three lists out of the forty-one sent in as specially interesting. Messrs. Ewing's is comprehensive and gives a reason for almost every vote. The Rev. C. H. Bulmer's ideas of "too much alike" are acted on in his list; whilst Mr. S. R. Whitwell adds to each Rose a number signifying its position and value as an exhibition variety.

Messrs. EWING & Co.'s selection.

"Best six Tea or Noisette Roses for general purposes, second best six, next twelve, and third twelve."

- | | |
|--|-----------------------------------|
| 1. Gloire de Dijon (not a true Tea) | 13. Rêve d'Or |
| 2. Maréchal Niel (for climbing under glass or on walls) | 14. Aline Sisley |
| 3. Niphetos (for pots, planting out under glass, forcing, and low walls in the open air) | 15. Duchess of Edinburgh (Veitch) |
| 4. Perle des Jardins (the best yellow for pots) | 16. Homère |
| 5. Madame Falcot (the best of its colour for cutting in the bud state for button-holes and bouquets) | 17. Innocente Pirola |
| 6. Isabella Sprunt (the best of its colour for the same purposes as Madame Falcot) | 18. Letty Coles |
| | 19. Madame Bravy |
| | 20. Madame Bremont |
| | 21. Madame Camille |
| | 22. Madame Charles |
| | 23. Madame Denis |
| | 24. Madame J. Margottin |

The following are equal for many purposes to the above:—Catherine Mermet, Climbing Devoniensis, Old Devoniensis, Jean Ducher, Louise de Savoie, Madame Lambard, and Marie Van Houtte.

- | | |
|--|---|
| 7. Rubens | 25. Goubault (extra fragrant) |
| 8. Céline Forestier | 26. Viscomtesse de Cazes |
| 9. Bougère | 27. La Boule d'Or (under glass only) |
| 10. Lamarque | 28. Madame Damazin |
| 11. Solfaterre | 29. Abrieote |
| 12. Triomphe de Rennes | 30. Madame T. Janin (for small buds only) |
| Equal to the above for various purposes are David Pradel, L'Enfant Trouvé, Comte de Sembui, Madame C. Kuster, Adrienne Christophle, Perle de Lyon, Belle Lyonnaise, Cheshunt Hybrid (not a true Tea), Madame Willermoz, Souvenir d'un Ami, and Comtesse de Nadaillac. The last variety will probably go up higher when more experience has been had of it. | 31. Madame Trifle |
| | 32. Madame Cecile Berthod |
| | 33. Marie Guillot |
| | 34. Reine de Portugal (this Rose and Marie Guillot would be amongst the "best" if they opened freely) |
| | 35. Souvenir d'Empereur Maximilian |
| | 36. Souvenir de Paul Neyron |
| | (Some of this season's Teas and hybrid Teas promise well, but we do not name them till we have proved them more fully.) |

Rev. C. H. BULMER'S selection.

- | | |
|-----------------------------|---------------------------|
| 1. Maréchal Niel | 18. Triomphe de Rennes |
| 2. Catherine Mermet | 19. Jean Ducher |
| 3. Marie Van Houtte | 20. President |
| 4. Souvenir d'Elise | 21. Céline Forestier |
| 5. Madame Bravy or Sertot | 22. Cheshunt Hybrid |
| 6. Caroline Kuster, N. | 23. Belle Lyonnaise |
| | 24. Adam |
| 7 { Devoniensis | 25. Madame Céline Noirey |
| { Climbing Devoniensis | 26. Jean Pernet |
| 8. Niphotos | 27. Anna Ollivier |
| 9. Madame Margottin | 28. Innocente Pirola |
| 10. Comtesse de Nadaillac | 29. Madame Lambaré |
| 11. Souvenir de Paul Neyron | 30. Madame Camille |
| 12 { Souvenir d'un Ami | 31. Perle de Lyon |
| { Souvenir de Madame Pernet | 32 { Madame Falcot |
| { Comtesse Riza du Pare | { Safrano |
| | 33. Madame Berard |
| 13. Gloire de Dijon | 34. La Boule d'Or |
| 14. Rubens | 35. Narcisse |
| 15 { Alba Rosea | 36 { Beauty of Glazenwood |
| { Eugène Desgaches | { Fortune's Yellow |
| 16. Madame Hippolyte Jamain | |
| 17. America, N. | |

Mr. E. R. WHITWELL'S selection. (Best six, second best six, and next best twelve Roses.)

- | | |
|---------------------------------|-----------------------------------|
| 1. Belle Lyonnaise, 6 | 13. Madame Margottin, 21 |
| 2. Gloire de Dijon, 24 | 14. Anna Ollivier, 16 |
| 3. Bouquet d'Or, 15 | 15. Jean Ducher, 12 |
| 4. Maréchal Niel, 1 | 16. Rubens, 10 |
| 5. Marie Van Houtte, 5 | 17. Madame Berard, 17 |
| 6. Souvenir d'un Ami, 11 | 18. Souvenir d'Elise, 3 |
| | 19. Devoniensis, 23 |
| 7. Homère, 22 | 20. Souvenir de Madame Pernet, 19 |
| 8. Dne de Magenta, 28 | 21. Adam or President, 13 |
| 9. Madame Hippolyte Jamain, 7 | 22. Comtesse de Nadaillac, 8 |
| 10. Catherine Mermet, 2 | 23. Madame Willermoz, 18 |
| 11. Souvenir de Paul Neyron, 14 | 24. Alba Rosea or Madame Bravy, 9 |
| 12. Niphotos, 4 | |

The number given on the right of each name is the order in which I should place them for exhibition purposes.—E. R. W.

Once again let me express my grateful thanks to those who have helped by their lists, and especially to those who have not contented themselves by a simple list, but have also by their grateful recognition of the labour involved made my task all the easier; to one and all, a rosy future.—JOSEPH HINTON, *Warminster*.

TWO KENTISH GARDENS.

HAVING already discoursed on Masealls I must now proceed to say a few words on Weirleigh, the residence of our genial and worthy friend Mr. Harrison Weir, whose house, as I have said, stands on a hill. Externally at a distance it looks odd. I will not say how irreverently the Major speaks of it, but when you once reach it all feelings of disparagement cease, and you at once recognise that you are at the house of an artist. It abuts on the road, and on the stone facings Mr. Weir has had carved a Gloire de Dijon Rose, which is represented as again coming out as a good climber ought to do—higher up. Inside the house is delightful; it is one of those Queen Anne houses by which Mr. Wadmore of Tunbridge has earned so good a name. Being built on the side of the hill it gives fine opportunity for many tasteful contrivances. And what can be said of the view from the reception rooms? The whole end of the dining-room, a lofty and well-proportioned room, is one large window, and from it a view unsurpassable in its character is obtained. The valley of the Medway lies stretched out before you with all its luxuriant beauty, Hop gardens, orchards, and abundance of grand foliage. In the near distance is Maidstone; while stretching out on the sky line you have the backbone of Kent, the range of hills which run behind Maidstone on to Lenham and the heading off by Eastwell and Wye to the sea. A little further to your right many a quiet village and country seat is seen embosomed in foliage, including that white house in Linton, the residence of Viscount Holmesdale, from whence John Robson used to delight the readers of the Journal in days now past. A little further on is Sir Edmund Filmer's near Sutton Valence; and wherever, in fact, we turn, some fresh scene of pastoral or woodland beauty delights the eye.

The object of Mr. Weir in his garden has been to produce picturesque results in each separate place rather than a grand general effect; so that as you go round the grounds you come on bits which, like those in a picture, delight you by their completeness in themselves while in no way interfering with the general effect. As you enter the garden from the house you come on a shrubbery in which is arranged a very good collection of Ferns, a result you would never have expected when you entered the place. In walking round the shrubbery you are continually meeting unexpected effects produced by seemingly small means. Here is a mass of Rudbeckia, there of Anemone japonica, mixed

with smaller plants, and so arranged that variations of colouring should be combined with elegance of form. Here you turn off to a little nook from whence there is a delightful glimpse of a woodland glen close by; and here is a walk shaded with Apple trees which must be a real delight in spring time when the trees are in bloom. Mr. Weir, as most of your readers know, is an experienced fruit-grower, and brings up from time to time to the Royal Horticultural Society specimens of his skill, especially in Grape-growing. Cordon trees were doing well and bearing some fine Apples. In his two houses were some Vines exceedingly well grown. But unquestionably the glory of the place, as far as fruit-growing is concerned, was the ground vinery. I have been through many gardens in my time. I have talked over these vineries with good old Mr. Rivers of Sawbridgeworth, and have seen them there; this was many years ago, how many I am afraid to say, but never since then have I in any garden seen an attempt at following out Mr. Rivers' plan. Indeed I cannot call to recollection any ground vinery; but after seeing Mr. Harrison Weir's very successful vinery I am induced to ask why they are not more often attempted. The length of his vinery is 36 feet and formed of six lights 6 feet each. The Vines are planted in a bed outside and then brought in to the case. The bottom is lined with tiles, and the Vine led along under the span of the case; and here might be seen bunches of Madresfield Court large, shapely, with well-ripened and well-coloured berries, quite equalling those grown in a house. We counted between thirty and forty bunches. As far as I could see there was at least a bunch to every pane of glass. The frames are inexpensively made, glazed without putty, and can be easily lifted off and moved in any direction. These vineries are very useful for growing Strawberries in or for hardening off bedding plants. In fact they may be put to many uses; and I am sure that anyone seeing those of Mr. Weir's would at once say, "Well, I must try and have some of these." Such was my own impulse, but then came the unpleasant reflection of "no assets."

Mr. Weir, while not relying on bedding-out plants, does not despise their moderate use, and indeed has been very successful in his hybridising of Pelargoniums, one very beautiful pink variety being especially worthy of notice.

Returning to the house we came upon a collection of Auriculas apparently in most robust health. Contrary to all the rules and directions so constantly given, the plants were standing out in the open exposed to rain, and in pots about twice the size of those in which they are ordinarily grown. They had their offsets in abundance, and were as healthy a lot in a small way as I have seen for some time. I do not know how they will fare when brought into their winter quarters, but at present they look uncommonly well.

Such, then, is Weirleigh, the home of a real artist, of a true lover of Nature. He has brought his art to bear in adding to the natural beauty of the place, and he has truly learned the truth that *Ars est celare artem*.—D., *Deal*.

LAWN TENNIS GROUND.

SEEING in your esteemed Journal that one of your correspondents desires some hints as to the formation of a lawn tennis ground, I have much pleasure in sending you the following few remarks, which I hope may prove of service. To begin with, a full-sized court for four players is 26 yards long by 12 yards wide. As much play takes place at the extreme ends or "back lines" of the court, a considerable margin is required at each end; the total length of the tennis ground should therefore, if practicable, be not less than 33 or 34 yards. My own tennis ground is at present only 18 yards wide, but it would be preferable to have it considerably wider than this so as to allow of the position of the court being moved a little one way or the other, and thus obviate wearing out the ground unduly. It is generally a good plan to have a little drainage material laid under the turf, so that the ground will not be so liable to play "dead" after rain.

If a wire fencing about 6 feet high is placed at each extreme end of the ground, and a lower fencing about 3 feet high running along each side, this will be found to save a great amount of superfluous muscular exercise in "fielding" the balls. If neatly put up and painted dark green this wire fencing does not appear too prominent in the grounds.

The ground should be as nearly level as possible, as uphill or downhill playing is most undesirable.—A. T., *Liverpool*.

IN reply to "W. F. M." I desire to state that the regulation size of tennis courts is 78 feet by 36 feet. Outside this there should be at least a yard all round, but better if it is two—namely, 85 feet by 42 feet of level lawn. Tennis lawns are

generally made quite level, which I think is a mistake, especially if the soil is of a stiff moist nature. It is much better if the ground is kept a little higher in the centre, say 4 or 5 inches, so that when a heavy rain occurs much of it passes off to the sides and ends, and the ground is quicker dry and fit to play upon sooner than when made perfectly level, and the greater part of the rain having sunk into the ground. It is very essential to have a firm surface; and for this reason, where the soil is clay or is wet, it is a good plan, after having levelled and consolidated the ground, to spread about an inch of clean coal ashes over it before laying down the turf. In addition to this it should be previously well drained. On light dry soils less trouble is necessary to have a fair tennis lawn; indeed, it may be played for "home practice" on any lawn where there is a little less room than is required for full-sized courts, and although it is not quite level.—R. INGLIS.

[Messrs. James Carter & Co. and other correspondents have also stated the regulation size of tennis grounds, but state that the size is generally governed by the extent of lawn at command.]

DEATH OF THE REV. JOHN HUYSHE.

WE regret to learn of the death of this venerable gentleman, who, after a period of failing health, expired at Clysthydon, Devon, on the 19th inst. Mr. Huyshe was born in 1800, and he had been rector of Clysthydon for half a century. He was one of the oldest magistrates of the county, and was held in the greatest estimation by all who knew him. He was an earnest worker in the interests of pomology, and it will be appropriate to submit

Fig. 71.—Huyshe's Prince Consort.

the results of his labours as a raiser of Pears. The accompanying account of the "Royal Pears" first appeared in the "Gardeners' Year-Book" of 1867.

The Royal Pears have a just claim to such a title. Raised as

they were by the descendant of ancient royalty, introduced as they have been at the table of royalty, and bearing as they do right royal names, what better claim could they have to such a designation? In their origin, too, they are no haphazard mongrels, but individuals of high descent and noble pedigree, and valuable additions to our pomological collections. "It is now about thirty years, or rather more," wrote Mr. Huyshe in the autumn of 1864, "since I began the practice of hybridising Pears, and the effects

Fig. 72.—Huyshe's Prince of Wales.

have been peculiarly striking. From Marie Louise hybridised with Gansel's Bergamot I obtained three pips from one fruit, and the produce of these were respectively the Pears now known as Victoria, Prince of Wales, and Princess of Wales." In a previous letter of the same year he says—"I send you another Pear, a seedling, being a hybrid between Beurré d'Aremberg and Passe Colmar. It has borne fruit this year for the first time, and what it may be of course I know not, but it seems to promise to be good." It did prove good, and we were subsequently informed that "Mrs. Huyshe wishes it to be named Huyshe's Prince Consort, in memorial of one whose character she greatly admired."

Such, then, is the origin of these four fruits, and the figures and descriptions on this and the following page will furnish a good idea of their characters and qualities.

HUYSHE'S PRINCE CONSORT.—This is the most recent of Mr. Huyshe's seedlings, and, as has been already stated, is of a different parentage to the three preceding, having originated from Beurré d'Aremberg fertilised by Passe Colmar. It is a noble Pear, of large size, and unusually bossed and uneven in its outline. The skin is grass-green even when ripe, and sometimes acquires a yellowish tinge, and very much covered with russet, exposing the green ground only in mottles. The flesh is yellowish, rather coarse-grained like that of Beurré de Rance, very juicy and melting, but not buttery; sweet, vinous, and with a very powerful melon or vanilla flavour, which is not only peculiar but highly agreeable. It is a splendid Pear, and ripens in the end of November and the beginning of December. With great liberality Mr. Huyshe presented the entire stock of this admirable Pear to the Royal Horticultural Society of London for distribution among the Fellows.

HUYSHE'S PRINCE OF WALES.—This was originally called Huyshe's Bergamot, not because it is at all like a Bergamot, but because the flavour bears some resemblance to that of its male

parent—Gansel's Bergamot. On it being represented to Mr. Huyshe that such a name was at variance with the appearance of the fruit, and might tend to mislead, he at once consented to the change, and it has now for some years been known as Huyshe's Prince of Wales. The fruit is large, sometimes immensely so; and we have seen it grown against a wall as much as 4 inches long and $3\frac{1}{4}$ in diameter. Its ordinary size when well grown is that represented in the figure. The skin is of a lemon yellow ground, veined with cinnamon-coloured russet. Eye small for the size of the fruit, and open. Flesh yellowish, tender, and fine-grained, melting and very juicy, richly flavoured, and with a high aroma.

HUYSHE'S VICTORIA.—This and the following made their appearance in public much about the same time, and at once took their position as fruit of high merit. In form Victoria is very characteristic. The two shapes which it usually assumes are represented in the accompanying figure, where it will be observed that one is very similar to Beurré d'Aremberg, with the very oblique stalk; while the other has the stalk inserted in a line with the axis, and is particularly short and stout. The skin is of a yellowish ground, and freckled and veined all over with thin, smooth, cinnamon-coloured russet. The flesh is yellowish, sometimes a little gritty at the core in dry seasons, and melting; very juicy, rich, sugary, and vinous. It is in use during December and January.

HUYSHE'S PRINCESS OF WALES.—This is the third of the produce of the "three pips from one fruit," and like Victoria varies much in form. Sometimes it is quite cylindrical and pinched in at the middle with a sort of waist, even more so than is represented in one of the figures. The skin is like that of a handsome Marie Louise, with a smooth lemon yellow ground colour, sprinkled with patches, veins, and dots of pale cinnamon-coloured russet. Flesh of a deep yellow colour; and in specimens received from Mr. Huyshe in 1865 was very melting and abundantly juicy, fine-grained, richly flavoured, and with a very high aroma. That same season it was presented to the Princess of Wales at Sandringham, who was graciously pleased to express herself very highly of its great merits. It is ripe in the end of November.

Such a measure of success as has attended Mr. Huyshe's efforts rarely falls to the lot of hybridisers. It is, however, but the reward of intelligence well directed to the attainment of a certain end. Not only is it necessary to select and carefully hybridise the parents, but, says Mr. Huyshe, "I am careful now in sowing only the round pips, not those that are flat-sided. I have only one more tree, a hybrid between Beurré d'Aremberg and Passe Colmar, from a flat-sided seed, and the difference is quite wonderful."

Those who desire a memento of a kind, industrious, and estimable man, cannot do better than plant the quartette of Pears which he succeeded in raising, and the merits of which have been proved in many gardens.

ORCHIDS IN FLOWER.

OCTOBER is by no means the best time of the year to see Orchids in their best condition, but notwithstanding the dullness of the season and the paucity of flowers in other departments, the Orchid house is still very attractive. On visiting two or three collections a few days since I was agreeably surprised to see the number of species in flower, some of them being fine specimens. Conservatories and plant houses generally are alike dull at this time of the year and onwards, till the Dutch bulbs, Primulas, Cinerarias, and Chrysanthemums come in to brighten their appearance, and the Orchid house lately has been anything but lively; but now and a little later on there is and will be many good plants flowering.

Amongst the most remarkable and ornamental Orchids that I noticed in my journey the following may be mentioned. *Angræcum falcatum* was growing in a basket suspended from the roof, and bearing numerous spikes of pure white flowers, the spur of which has a peculiar bend. This is a little gem in its way, although the flowers are not so large as its near relation *A. Scottianum*, which was just past flowering. *Aërides quinquevulnerum* was also in flower; this is considered by many to be one of the handsomest of the *Aërides*. Of *Dendrobies* that were in good condition and flowering freely were *D. bigibbum*,

D. triadenium, *D. cumulatum*, and *D. formosum giganteum* with two flowering spikes and three flowers on each, the petals and sepals being pure waxy white with a large spot of bright yellow on the base of the labellum.

Cattleyas were making a show, for I had the pleasure of seeing some of the good old kinds—viz., *C. labiata*, *C. exoniensis*, and *C. maxima* with two growths and three flowers on each. The

Fig. 73.—Huyshe's Victoria.

Fig. 74.—Huyshe's Princess of Wales.

latter is a grand species when well grown; the flowers are of great size and substance, and the veining of the labellum is very handsome. *Cypripediums* were well represented, there being several fine species in flower; in fact, some are never out of flower, such as *C. Sedeni*, *C. Roezlii*, and *C. longifolium*. They always seem to be in season, and are always appreciated; but *C. niveum*, in my estimation, is the best of the genus, and is always welcome;

so also is *C. concolor*, which makes a pleasant companion to the former. *Lælia Dayana* was flowering freely in the *Odontoglossum* house, and associated with its gigantic form *L. pumila* makes a grand display. I was much surprised to see the small pseudo-bulbs producing the enormous flowers they did. These two species deserve to be more extensively cultivated than they are. *Lælia Perrinii* was in fine condition. The flowers vary considerably in size and colour; some of the varieties are a dark rose or purple colour, others quite pale, and I noticed one named *L. Perrinii alba* that had almost pure white sepals and petals with a blotch of deep purple on the end of the labellum.

Oncidiums were numerous, amongst them being a remarkably fine variety of *D. macranthum* with one long spike of bloom; the flowers were of immense size and of a beautiful soft lemon yellow. *O. verrucosum* was in flower in many varieties. One named *O. verrucosum* var. *Rogersii* was so much different from the typical form that one would suppose it was another species from the great size and substance of the lip. *O. incurvum* is a pretty species now in flower, producing branched spikes from 3 to 4 feet long; the flowers, as the name implies, are incurved and are of a beautiful pale lavender colour. *O. ornithorhynchum* is a little gem, the flowers of which are delightfully fragrant, differing very much from a neighbouring plant of *O. bracteatum*, which produces flower spikes 4 to 5 feet long; the spikes are clothed at intervals with long sharp-pointed bracts, giving them rather a singular appearance. Of *Odontoglossums* there were many in flower, but the following are a few of the best—viz., *Odontoglossum Alexandræ* in numerous varieties, not two plants being alike; *O. grande* I saw in splendid condition, and *O. Rossii* var. *majus* growing in a pan which was literally covered with flowers. I must not pass over the little Indian *Crocuses* without giving them a word of praise. The most common are now in season—namely, *Pleione lagenaria*, *P. maculata*, and *P. Wallichiana*, as these flower without the foliage; the flowers are shown off to the greatest advantage by pricking some small seedling Ferns between the pseudo-bulbs as the old leaves drop off, and by the time the flowers are fully expanded the Ferns will have grown a little, which help to tone down the glow of colour produced by so many flowers. *Polystachya grandiflora* is a species not frequently met with, and when seen grown to perfection it is indeed a curious and highly interesting species. The flowers are placed on the spikes so as to appear as if turned upside down, assuming the appearance of little hoods.

Phalanopses were represented by *P. amabilis* and *P. grandiflora*; their good qualities are too well known to require anything said about them. *Saccolabium Blumei* was producing two fine spikes of its rosy-coloured flowers. *Vanda tricolor superba* was also bearing two fine spikes of flowers, which filled the house in which it grew with its delicious perfume; and *Vanda cærulea*, a species not often seen in flower, was producing nine large flowers on one spike of a light lavender colour. Last, but not the least, the old and highly valued *Zygopetalum Mackayi*. I could extend the list, but space forbids; let it suffice, I was highly delighted with my day's outing among the Orchids and their growers.—W. K.

FROM the Agricultural Returns issued by the Board of Trade, we learn that ORCHARDS IN GREAT BRITAIN again show a satisfactory increase, their acreage being this year returned as 180,000 acres, against 176,000 in 1879 and 165,000 in 1878. Market gardens have also increased from 41,000 acres to 44,000 acres, and the collectors report both with regard to orchards and market gardens that there is a growing demand for fruit and vegetables, especially in the neighbourhood of towns. The uncertainty of the climate for fruit-growing must always, however, tend to restrict the extension of fruit plantations except in naturally favoured districts. A special return of the acreage of woods and plantations has been obtained this year, the last return of this nature having been made in 1872. Since that date the acreage appears to have increased from 2,187,000 acres to 2,409,000 acres, or nearly 10 per cent.

— THE EXHIBITION OF CHRYSANTHEMUMS AT FINSBURY

PARK, referred to in a recent issue of the Journal, is now open to the public, and although the plants are not yet at their best there is promise of an exceptionally fine display. About 1200 plants are arranged in a long temporary erection near the lodge entrance to the Park, and they appear to have received admirable attention, for in vigour of growth, healthiness of foliage, and size of flower buds they are the finest we have seen this season. Many flowers are already open, that handsome variety *Elaine* being the most noticeable; but in the course of another week a great advance will no doubt be made. One hundred and fifty varieties are represented, including all the best in commerce.

— MR. RECORD writes as follows concerning the DOYENNÉ BOUSSOCH PEAR:—"Although there is no lack of good autumn Pears from which intending planters can make a suitable selection, some varieties are not so reliable as others, and it is therefore well to know which are the best. I would advise that the above variety be included. I have proved it to be a Pear of the finest quality. It is large and noble in appearance, of rich flavour, flesh melting and juicy, skin very thin, and when ripe of a russety lemon colour. It is also a capital cropper, and does well against a wall with an eastern aspect in the south of England, but northwards it would need a good south wall. Worked on the Quince stock the tree has a moderately vigorous growth, and generally forms plenty of fruit buds; it also does well as a pyramid, though it ripens somewhat later. I have had it in use from the latter part of October to the middle of December, and it was always welcomed at table as a first-rate dessert Pear."

— WE are requested to announce that the Committee of the WIRRAL ROSE SOCIETY intend holding their Show next year on July 16th, the Saturday following the day of the provincial Show at Sheffield of the National Rose Society. We have also received the schedule of the Wirral Show, and observe that the classes are more numerous and the prizes more valuable than last year. Eleven of the classes are open to all comers, including the amateurs' class for thirty-six varieties, the first prize of which consists of a piece of plate value £10. The local prizes, which are good, are open for competition by growers within the Hundred of Wirral and ten miles round the Liverpool Exchange. Mr. John Smith, Woodside, Rockferry, is the Secretary.

— WRITING on the productiveness of the MAGNUM BONUM POTATO, Mr. R. W. Lumsden, of Newstead, Bridge of Allan, informs us that he planted 1 lb. weight of this Potato on the 12th of April last, and when they were taken up on the 16th of October the produce was 114 lbs. 3 ozs. Some of the Potatoes were 6 and 7 inches in length. Our correspondent does not say whether he cut the sets into single eyes and grew them the same as Mr. James Pink did Eureka and Snowflake a few years ago, and obtained of the former 672 lbs., and of the latter 405 lbs. from 1 lb. of seed each. If Mr. Lumsden had not recourse to the system indicated his crop is a very heavy one; but under ordinary culture the Magnum Bonum is known to be highly productive, and in some soils the tubers are of excellent quality.

— IN the Cape House at Kew a pretty little bulbous plant is now flowering—namely, *NERINE CRISPA*. The leaves are small and narrow, the scape rising to the height of a foot and bearing an umbel of about a dozen flowers. These are also very small, scarcely exceeding an inch in diameter, the perianth divisions being narrow, crisped or undulated, and spreading, of a delicate pinkish tint. It is very distinct, and appears to thrive well under pot culture. Another attractive species is flowering near the above—viz., *Nerine pudica*, which has white somewhat funnel-shaped flowers, very dissimilar in appearance from those of *N. crispa*. Three or four flowers are borne on each scape, the white being pleasantly relieved by a faint streak of pink down the centre of the perianth divisions.

— WRITING to us on the WEATHER IN LANCASHIRE a Grange-over-Sands correspondent states:—"We have not had any snow here, but severe frost. On the night of the 19th inst. the mercury fell to 23°, or 9° of frost; on the 20th to 27°, or 5° of frost; and on the 21st to 22°, or 10° of frost."

— WE have received from Messrs. Sutton & Sons of Reading a sample of MAGNUM BONUM POTATOES, with a request that we should test their quality. We have done so, and found them excellent. Had they been more floury their shape when cooked would not have been retained, while at the same time they were melting, the flavour delicate and most agreeable. On all soils the tubers are not equally good, and they usually improve in quality as the spring approaches.

— WE recently noticed an admirable specimen of MIKANIA PULVERULENTA trained over a pyramidal trellis in a large pot, and as the trellis was well covered with foliage the effect was very good. The leaves are palmately divided with irregularly cut segments, very dark green, of a velvety appearance. The plant is climbing in habit, and may be trained up the rafters of a stove or employed as a plant for the stages. A compost of rich loam with a good proportion of sand and abundant drainage suit it well.

— REFERRING to LIFTING UNRIPE POTATOES, Mr. W. Roberts, of Penzance, states that "In Cornwall the early varieties are almost without exception dug immediately they finish growing, be the stalk green or not. I am quite aware that many gardeners allow Potatoes to remain in the ground until the stems are quite dead; but surely a plan that is generally adopted here is worth trying, considering that several hundreds of tons are dispatched weekly to the London and other markets."

— A CORRESPONDENT writes—"There is every prospect this autumn of a fine display of CHRYSANTHEMUMS IN THE VICINITY OF LIVERPOOL. The fine summer weather in the later stages of their growth thoroughly ripened and matured the wood. Last year the growth was rapid and soft, and under such conditions well-developed blooms were scarcely expected. The weather has during the past week or two been most favourable for the early development of the flower buds, and if all goes well for a few more weeks some magnificent blooms both as regards colour, size, and form may be expected at the Liverpool Show."

— FROM the same source we learn that "THE ALLAMANDAS AT NORRIS GREEN are still magnificent. The plants are grown in pots and are trained over the roof of the stove, and have been blooming continuously for some months past. The flowers are not so large now as they were earlier in the season, although they are quite as numerous."

— A CORRESPONDENT writing relative to the WEATHER NEAR SHEFFIELD states:—"We have had a week of very cold and frosty weather here. The thermometer has registered from 4° to 10° below freezing point on different nights, Tuesday night being the most severe, accompanied with a slight fall of snow; not sufficient, however, to afford protection to many plants, as the immature growth has been blackened by the cold, and now the foliage is fast falling, leaving some trees as denuded as in the depth of winter. The crop of fruit about here has not been good, neither has the quality been excellent; but almost all kinds have made good growth, and with plenty of fruit buds let us hope that these early frosts have not injured them."

— Two elegant plants for the tropical fernery are SELAGINELLA ERYTHROPHYLLA and S. HÆMATODES, both of the caulescent type, with flattened closely-pressed fronds of triangular form. S. erythrophylla is particularly neat, the fronds appearing as if they had been carefully pressed in a book, so flat and even are all the leaflets, which are of a fine dark green hue. S. hæma-

todes has rather larger and coarser fronds of a bright fresh green colour, but the leaflets in that are also so closely placed as to bear the pressed appearance which characterises the other species. Both succeed well in shallow well-drained pots or pans containing a light compost of peat, loam, and sand, and they may be easily increased by division.

— UNDER the attractive title of the "GARDENS OF THE SUN; or a Naturalist's Journal on the Mountains and in the Forests and Swamps of Borneo and the Sulu Archipelago," a new book is announced by Mr. F. W. Burbidge. The admitted ability of the author as a writer and practical horticulturist, and his peculiar field of observation, invests the coming volume with considerable interest.

— THE *Journal of Forestry*, in an excellent article on the advantages of AUTUMN PLANTING, concludes as follows:—"In nearly every instance of forest tree planting the work can be better and more expeditiously performed in the autumn than in either the winter or the spring, and by doing so the losses from everything but game are reduced to a minimum. Still, the dilatory and less successful practice of winter and spring planting generally prevails in most parts of the country, and often in circumstances where no excuse can be made for neglecting to plant in the autumn—the most economical as well as the most favourable season for the operation. As knowledge spreads, and the principles of plant life are better understood among those in charge of forests and plantations, autumn planting will be more generally adopted, with much saving to the landowner and more success and credit to the skilful operator."

COMING CHRYSANTHEMUM SHOWS.

Now that the Chrysanthemum season may be said to have arrived, and the exhibitions fast approaching, a few remarks upon the provisions the various societies have made to ensure good displays may not be uninteresting to some of our readers. We have before us the schedules of nineteen Societies, some of which are exclusively devoted to the improvement of the Chrysanthemum, while others endeavour to render their exhibitions as generally interesting as possible by offering prizes for plants, fruit, and vegetables. In all, however, special provision is made for the Chrysanthemum.

The first Show on the list is that of the Brixton Society, which is to be held on November the 11th and 12th. Thirty-five classes are enumerated, fifteen being devoted to Chrysanthemums, the prizes varying in value from 40s. to 2s. 6d. Provision is made for specimen plants, which are usually very good there, and the various sections of cut blooms, which are also generally well represented. One speciality worth notice is a class confined to growers who have not previously taken a prize for Chrysanthemums. The Stoke Newington Society follows with an Exhibition on November the 15th and 16th. This old and well-known Society is solely devoted to the encouragement of Chrysanthemum culture. The most important class is that for a collection of ten specimens in 11½-inch pots, for which a six-guinea silver cup is offered as the first prize. The Borough of Lambeth Amateur Chrysanthemum Society will hold their sixth exhibition on November 15th, 16th, and 17th. The competition is confined to amateurs within a mile and a quarter of the Elephant and Castle, and yet the general good quality of the exhibits staged there is surprising. The prizes are not high, but they include four silver cups as first prizes. One stipulation, so far as we know, does not occur in any other schedule—viz., "that all blooms be shown as grown, and any exhibitor staging blooms or plants with the flowers artificially dressed shall be disqualified." The Putney Society will hold a Show of one day's duration on November the 16th, when a satisfactory display may be expected, the cut blooms being generally good there. There is nothing particularly noteworthy in the schedule except the class for the best collection of specimens of not less than twenty varieties, a silver cup and three prizes being offered. The Walton and Weybridge Exhibition will take place upon the same day, when, in the twenty classes devoted to Chrysanthemums alone, a display of considerable merit may be confidently expected. Curiously in the schedule that we have there is no intimation as to the value of the prizes. Standard plants are usually very good at Walton.

The Southampton Show will be held on the 16th and 17th,

Dartford on the 17th, Gravesend on the 17th and 18th, and Bristol on the same date as the last-mentioned. In all bountiful provision is made for Chrysanthemums, the first and the last also representing plants and fruit largely, and fine Shows are expected. On the 17th and 18th ult. the Finsbury Park Amateur Society will hold their first exhibition, which, judging from the influential patronage accorded them, may be expected to be satisfactory. On the same dates the Borough of Hackney Society will hold an exhibition at the Royal Aquarium, Westminster. Liberal prizes are offered, including no less than five silver cups, two being given by the Aquarium Society. The other prizes vary from £2 to 5s., sufficient in most instances to give hopes of a close competition. The Shrewsbury Show will be held on the 18th. The schedule includes classes for fruit as well as Chrysanthemums, the prizes being generally good and the classes "open to all."

The Kingston Society will, it is announced, hold their Exhibitions on the 18th and 19th ult., the schedule including the usual liberal array of prizes. Two timepieces and a watch, value each four guineas, constitute the first prizes in three of the chief classes, but the principal interest of the Exhibition will centre in the competition for the champion challenge vase, value twenty-five guineas. It will be remembered that Mr. Harding, gardener to J. D. Galpin, Esq., Birstal House, Putney Heath, was the winner last year, followed by Mr. Moorman, gardener to Miss Christy, Coombe Bank, Kingston; and Mr. McPherson, gardener to S. Page, Esq., St. Leonard's Lodge, Surbiton. That the competition will be as close this year is confidently expected. The Croydon Show will take place on the 19th and 20th ult., but there is nothing in the schedule to call for special notice. The Maidstone Chrysanthemum and Fruit Society will hold their Exhibition on the 19th ult. Thirteen classes are devoted to Chrysanthemums and nine to fruit, of which the display is sure to be very good. Three silver cups are offered in the former classes, one being valued at ten guineas, in an open class for thirty-six blooms of incurved large-flowered varieties. This will no doubt induce good competition. The Liverpool Horticultural Association will hold their first Exhibition of Chrysanthemums, fruits, &c., on the 23rd and 24th ult. Liberal prizes are offered, and a satisfactory exhibition may be expected. The success of the Chrysanthemum Show at Richmond last year has induced the Society to hold another this year, which will take place on the same dates as the Liverpool Show. The Northampton Chrysanthemum Society will hold their Exhibition on the same date as the above. Four cups are offered valued at three guineas each. The Show last year was an excellent one. The latest Show of which we have any information is that of the Birmingham Society, which takes place on the 24th and 25th ult. Provision is made for the exhibition of plants, fruit, and flowers, in addition to the Chrysanthemums. Among the latter the chief class is for nine specimens (which are usually very fine at Birmingham), the first prize being a silver cup value £5.

Such is a brief review of what may be regarded as the chief items of interest to the grower or exhibitor of Chrysanthemums as regards the schedules of the Societies, and indicates what may be expected to be the most important points in the forthcoming contests.

TRANSPLANTING FRUIT TREES.

THE present is the best time in the year to transplant fruit trees. About this time last year I shifted some hundreds, and all of them have done well since, although some of them might have been thought too old to be transplanted successfully. Indeed some were quite past bearing fruit, and they were shifted with the view of putting fresh life into them, and this has been done to a great extent. Trees of many kinds of fruits were so treated, such as Peaches, Apricots, Plums, Cherries, Apples, Pears, Gooseberries, and Currants.

Before beginning to shift a tree a large heap of soil was prepared as fresh material for the roots. This consisted of good loam and lime rubbish, with a little decayed cow dung for the Peach trees; loam and dung for the others; and a stronger mixture still for the Gooseberries and Currants. To the loam for the whole of them was added a good quantity of road scrapings, which contained horse droppings and lime, as the roads about here are formed of limestone, a material which may be used with advantage for all fruit trees. I do not give any exact proportion of the material, as in this I am always guided by the quality of the loam or health of the trees. This, I think, is best, as soils and situations differ so much that we must be our own guides in such matters. In wet soils and low situations draining material should be at hand. Broken bricks are most suitable, but failing them rough ashes answer the purpose well. When it can be managed the

trees should not be replaced on the precise spot where they have been growing previously, but a few feet or yards from it. This allows the hole to be made and the site prepared before disturbing the tree, and it may then be transferred to its new quarters without loss of time.

In planting a tree an attempt should always be made to raise it above the ordinary level of the ground. This is one of the great secrets in successful fruit-tree culture. Plant a tree deep and all hope of its doing well may be abandoned. Many fruit trees become cankered, defective in growth, and unfruitful owing to their being planted too deeply. The holes should be made of a size proportionate to the dimensions of the tree. No hole should, however, be less than 6 feet square. The soil must be taken out to the depth of 3 feet at the least, and then 18 inches of drainage should be placed in. Over this put turves grassy side downwards, and then fill up to the level of the ground with the soil which has been prepared for planting. It should be beaten or trodden quite firmly, and then it is ready for the reception of the roots.

In lifting the trees a trench should be thrown out all round some 2 or 3 feet from them. The soil may then be gradually removed from the roots, digging inwards and under with a fork, and all the thick fibreless roots can be cut well in with a sharp knife. A small ball of roots and soil must be retained round the base of the stem, and in this form it should be placed on the new ground. More of the fresh soil should then be worked amongst the roots, afterwards adding plenty of it all round so as to form a firm compact mound. This should all be done when the soil is dry and in good working order, when it can be trodden firmly round the tree. As the planting of each tree is finished a strong stake may be driven into the soil a few inches from the stem, and some part of the branches or stem must be made secure to this by means of a strong hay or straw rope. Until the roots have taken firm hold of the soil the wind must be prevented from shifting the roots in any way. This must be observed most particularly, as no tree that is newly planted will thrive if the wind disturbs it. To finish operations about 3 inches of half-decayed manure can be spread over the mound, and may be allowed to remain on until it has decayed into the soil.

These remarks apply to all fruit trees, but of course those planted against the walls require no stakes to support them. Few roots will be made after this time until the spring. Trees transplanted now should not be pruned until January or February, but where very large trees are transplanted some of the largest of the branches may be taken off. As a rule large trees are better cut-in when they are shifted, as the young growth they make afterwards is fruitful and satisfactory. The result of this work will be shown a little in the next season, but it is in subsequent years that it will be most apparent, when healthy growth of a moderately strong character and plenty of fruit buds will well repay all outlay.

As illustrating the good results which follow such work I may say that I have some very handsome standard Cherry trees in the garden. For years previous to this season they have made an enormous amount of wood, and never matured any fruit. Last autumn I had them lifted and replanted in the manner indicated above. Last season they bloomed freely, set and ripened more fruit than they had done for years, and all the wood they have made this season are only little spurs of the fine fruit buds.

The stations for Gooseberry and Currant bushes do not require to be so carefully made as for other trees. Plenty of manure and no drainage suits them. Out of many scores of bushes shifted last autumn I did not lose half a dozen. Many were very old, and yet this season they fruited remarkably well.—A KITCHEN GARDENER.

ADIANTUM CAPILLUS-VENERIS VAR. CORNUBIENSE.

OF the five or six forms of *Adiantum Capillus-Veneris* none exceeds in beauty the remarkably elegant variety here illustrated (fig. a), which bears a nearer resemblance to that handsome Maidenhair Fern, *A. farleyense*, than any other hardy Fern. It was found near the cutting of the St. Ives (Cornwall) railway about 1874 by Mr. Trevithick, and named *A. Capillus-Veneris* var. *cornubiense* by J. Tyerman, Esq., of Tregony. At first it was supposed to be a two-year-old seedling of the typical species (the fertile and sterile pinules of the species, *A. Capillus-Veneris*, being represented at b in the engraving) which is found at Tintagel, which, however, never produces fronds the same size the third year or afterwards as it does the second year, whereas this is constant to its size. Too much cannot be said in favour of this grand acquisition to our hardy Ferns. The pinules are nearly palmate, very deeply cut, sometimes into twelve or thirteen

segments, quite barren, therefore it can only be propagated by rhizomes. The stipes are 3 to 4 inches long. The finest specimen in Cornwall, and perhaps in England, was shown at the Penzance Exhibition, grown by Mr. George Maddern, gardener to E. Bolitho, Esq., Trewidden, which measured quite 3 feet in diameter. It is of drooping habit, and if grown in a pan will soon cover it all round. The specimen from which the accompanying engraving

was prepared was given me by Mr. J. G. Mitchinson, and Mr. F. W. Burbidge was kind enough to make a sketch of it.

Another very desirable variety is *A. Capillus-Veneris* var. *magnificum* (Lcc). The fronds of this useful and attractive Fern are much larger than those of the species, being from 12 to 15 inches long by 4 inches broad, and, like those of *cornubiense*, are gracefully curved; but the pinnules are not so deeply cut, as

Fig. 75.—*ADIANTUM CAPILLUS-VENERIS* VAR. *CORNUBIENSE*.

can be seen by fig. *c*. Another well-known form is *A. C.-V.* var. *daphnites*. This differs in a very remarkable degree from all other varieties; the pinnules of each of the branches are confluent (united), and the apex of the rachis dilated, spreading out the pinnules into a crest-like crispy mass. The stipes are ebony-coloured. It is not very unlike *Adiantum Luddemanianum*.

A. Capillus-Veneris var. *minus* is a very pretty form. The pinnules are not larger than the species but much prettier, measuring

sometimes 18 inches from the bottom of the stipe to the apex of the frond. The sori are brownish, sometimes two but usually three on a pinnule. There are two more varieties—namely, *A. C.-V.* var. *undulatum* and *A. C.-V.* var. *incisum*, both of which I am unacquainted with.—WILLIAM ROBERTS, *Penzance*.

LIFTING UNRIPE POTATOES.—I am much obliged to Mr. Luckhurst for replying to my notes on this subject. I did not,

however, intend to make any accusation against the wisdom of his method. I wrote simply with the object of stating my failure in my endeavour to follow him, hoping that some of your readers would set me right. I now see plainly that lifting the tubers while still growing is entirely contrary to Mr. Luckhurst's plan. Let us try to turn all our failures and the advice offered to us to good account in 1881, and thereby give this vegetable the care and importance it deserves.—A. K. B.

THE EFFECTS OF SNOW IN OCTOBER.

A NOTICE of some of the destructive effects of the heavy fall of snow that occurred on the night of the 19th and morning of the 20th of October, will not be out of place in the pages of the *Journal of Horticulture*, which has so often treated with great ability the subject of landscape gardening. In the wooded district from which I write, at an altitude of from 500 to 800 feet above the sea, we could look down, on the afternoon of the former day, upon the broad expanse of the Wealds of Surrey and Sussex covered with Oak trees and pastures. Everything was green and summer-like, for none of the leaves had fallen or even changed colour.

The next morning all this was hidden in snow, which was still falling thickly, and with us attained a depth, in places where it had not drifted, of 3 inches. Throughout the day the ominous creaking and crashing on all sides of us told of the splitting and fall of many a heavy branch, dismembering and disfiguring for ever the trees to which they belonged. The Oaks were the chief, if not the only sufferers. Heavily laden already with foliage and a more than usually great crop of acorns, the further weight of 3 inches of snow, which clung tenaciously to the whole surface of the trees, became to them much more than the last straw upon the camel's back. Sturdy branches that looked the type of strength and endurance were broken, twisted, and borne to the ground, much as some delicate plant might have been. The Oaks that were most injured were the broad-spreading symmetrical trees. One such tree, an object of interest, almost of affection to us all, is so crumpled and crushed that it looks as if some giant of our childhood days, all too heavy, had sat down upon it. We can now only hope that what our trees have lost in symmetry they will gain in picturesque effect. Elm trees have lost a few branches, Ash trees still fewer, and Beeches, of which there are some fine specimens about here, are unscathed. With regard to Conifers, although there are great numbers of Scotch Firs and Larch near us, I have not observed that they are damaged, and the same may be said of many other kinds of Conifers which are used for the decoration of lawns and grounds.

Within twenty-four hours from the commencement of its fall the snow was in great measure gone, and the earth again looked green, in remarkable contrast with its recent appearance. It has been stated that fifty years have elapsed since the occurrence of a heavy fall in snow in the south of England; but I am informed by a friend that many Oaks and other trees in this neighbourhood were greatly injured, whilst still in full leaf, by a heavy snowfall only twenty years ago.

It was interesting to observe how completely surprised the swallows must have been by the snow. I saw several of these birds skimming the snow over and over again in a vain search. I presume, for insects. The next day not one of the birds was to be seen, so little preparation in the way of arranging was necessary previous to their departure for the season to a warmer climate.—A SURREY PHYSICIAN.

AT 4 A.M. on Wednesday the 20th inst. a shower of fine hard snow commenced falling; this continued for about two hours, when large flakes came down thickly and continued falling till mid-day. Most of the deciduous trees still retain their foliage, upon which the snow gathered so heavily that the effect was most disastrous. Never have I seen or heard anything like it. After daybreak for some hours it was like a battlefield; reports followed each other in quick succession, occasionally merging into a regular volley, and down came the boughs crashing among the undergrowth, and spreading destruction on all sides. The Oaks suffered most, many trees having the entire head crippled, the whole of the branches being broken partly asunder and remain hanging down in most melancholy guise. Hundreds of others have lost some branches, so that many fine trees are hopelessly disfigured. The Beeches escaped with comparatively little harm owing to the fact of the more erect disposal of their branches, and the leaves had fallen off many of the upper branches. So fast fell the snow that it was only by repeatedly shaking it off the shrubs with poles that they were saved from permanent injury. A sharp frost followed on Wednesday night, covering the pools with ice and

nipping any tender growth left bare of snow. The frost did not continue, the snow gradually melted, and by Friday it had disappeared, but the lamentable evidence of its presence will long remain.—EDWARD LUCKHURST.

THE POTATO DISEASE AND RAINFALL.

WHILE I cannot, like a certain author, write "for ever" on the Potato disease, I desire to refer to a sentence in the letter of "AMATEUR, Cirencester," on page 370 in his reply to "INTERLOPER"—namely, "there are many other little difficulties against the excessive rainfall theory." Against any "little difficulty" I will adduce one great fact that I challenge your correspondent to disprove. It is this: In Lincolnshire when the rainfall is slight between April and October there is little or no disease, but when it is excessive the disease has ruined the crops. This has been uniformly the case. Never during a dry summer has the disease been prevalent, and never in a wet one has it been absent during the past thirty-five years. Any trifling exceptions to the contrary, such as recorded instances of the disease occurring under glass, are "trifling" indeed, and can have no weight against the one great actual fact adduced, which no amount of argument can explain away. I confine my remarks to Lincolnshire, and if the rain has a different effect in Gloucestershire, "AMATEUR," who appears fond of "theory," will no doubt be able to explain the reason. All experience proves that wet and muggy weather combined with a high temperature is favourable to the germination and growth of the Potato-destroying fungus, any theory to the contrary notwithstanding.—A LINCOLNSHIRE POTATO-GROWER.

GRAPES SHANKING.

WITH healthy growth and the "leaves quite green" in November it will be conceded that the wood of such Vines afterwards would not be extra ripe. As a somewhat similar question to asking why Grapes shank, it may be inquired, Why do Apples fall when half grown? and is it necessary to seek for the reasons during the fruiting year? My contention is that it is not. I contend that the constitution of all fruit is formed by heat natural or artificial during the previous year. Already the fruit bud to provide fruit for next season is either perfect or imperfect, and, in the north at least, materially will remain so. The Vine bud if unripe next year will develop into tendrils, bunches badly set, bunches with stoneless berries, or I maintain bunches the berries of which will shank.

Regarding the shanking of the Gros Colman Grapes that has been alluded to, I have some this year quite similar, and which I expected would shank, and in fact said so many times last winter. This is more especially a peculiar failing of the Gros Colman Grape. When the wood is imperfectly ripened the fruit sets comparatively well, stones well, but under such circumstances portions of some of the bunches shank. It is no argument that all do not shank, any more than it is that all Apple buds are ill developed, some not coming to maturity. In ripening, some fruit buds always take the lead.

I will advance a circumstance that I contend materially strengthens my argument, and which any of your readers who choose may see. This spring, having a few young canes of Gros Colman left unsold, instead of cutting them down I determined to fruit them, and now two of them are carrying eight bunches without a shanked berry. The berries are not so large as those on the permanent Vines, but the bunches are very good. Why is this difference? I think it is plain. Both the established and the young canes were grown up to October without fire heat, and except some being in pots they had exactly the same treatment, but the canes of the established Vines were three times the thickness of those in the pots, and consequently required more heat to ripen them, which they did not have. None of the other Grapes in the house have been shanked, and all alike have carried a light crop. I do not contend that other canes will not produce shanking, there is no necessity to do so, and, moreover, imperfect fruit buds are quite as likely to result from unhealthy Vines grown in undrained sour borders as they are to result from strong-growing healthy Vines, but which lack sufficient or proportionate heat. With well-ripened Vines, reasonable cropping and reasonable attention regarding Grapes, gardeners may sleep soundly.—JOSEPH WITHERSPOON, *Red Rose Vineries, Chester-le-Street*.

AUTOMATIC MOVEMENTS OF A FERN.—Dr. Asa Gray says:—Mr. E. J. Loomis of the Nautical Almanac Office, Washington, recently showed me a phenomenon which I suppose has never before been noticed, and which is commended to the attention of

botanists. A tuft of *Asplenium Trichomanes* gathered last autumn in the mountains of Virginia is growing in his house in a glass dish. About two months ago he noticed that one of the fronds—a rather short and erect one, which is now showing fructification—made quick movements alternately back and forth in the plane of the frond through from 20° to 40° whenever the vessel was brought from its shaded situation into sunlight or bright daylight. The movement was more extensive and rapid when the frond was younger. When I saw it on the 23rd of January its compass was within 15°, and was about as rapid as that of the leaflets of *Desmodium gyrans*. It was more rapid than the second hand of a watch, but with occasional stops in the course of each half vibration. This was in full daylight, next a window, but not in sunshine. No movement had been observed in the other fronds, which were all sterile and reclining, with the exception of a single one which was just unfolding, in which Mr. Loomis thinks he has detected incipient motion of the same kind.—(*Science Gossip*.)

FUNGI A RESULT, NOT A CAUSE OF DISEASE.

"S." appears to object to my positive statements. Have I not ample reason for being positive? Had I propounded a series of fanciful theories, and endeavoured to bolster them up by quoting the opinions of others, an apology would have been due to yourselves and your readers; but every statement of moment was supported by examples or facts derived from actual experience, and advanced, not merely for getting the best of an argument, but for the benefit of "gardeners and gardening." My "long and close observation about legitimate growth and legitimate functions having ceased before the disease attacks the Potato plant" not only will establish my case, but has already done so for fully fifteen years, for during all that time has it enabled me to save the crop with the exception of last year and one or two other seasons of untimely heavy rain. All who have adopted this invaluable method of avoiding loss from disease are aware of the difficulty of knowing to a day when the legitimate growth has ceased, and how easily a superficial observer may be deceived. "But," he will say, "how can I be deceived? Have I not had the clearest evidence before my eyes? Was not the haulm quite green and in full vigour when the plague spot appeared and spread over it with such rapidity?" Yes; but there was a cessation of growth, it may be of one or several days' duration, and it is then that I and "A NORTHERN GARDENER" and many more throw aside our pens and our coats and set to with a will to save the crop. This year once more all the Potatoes—early, intermediate, and late sorts—were lifted while the haulm was quite green, fresh, and unblemished, and no argument of "S." can upset the fact of my store sheds being full to overflowing with dry sound tubers. Talk of positive statements, what does "S." think of "A NORTHERN GARDENER'S" acquaintance who has adopted early lifting for forty years without a failure?

"S." wisely avoids any attempt to explain away the remarkable cure of blister in the Dr. Hogg Peach tree which I cited in my last note on this subject. That fine tree, and its abundant crops of excellent fruit since it has had no blister, is another of my facts which enables me to be positive. No doubt Peach blister has repeatedly occurred upon trees in houses, but it is invariably owing to faulty glazing or careless manipulation of ventilators. If anyone doubts this let them throw open a ventilator next spring when the foliage is young and tender and a strong wind is blowing from the north-east, and they will soon have positive evidence of its scathing power, as I had before dearly bought experience taught me better. Some twelve or thirteen years ago a remarkable example of the baneful effects of cold wind upon tender vegetation came under my notice. In a vinery all along the top of the house immediately under the ventilators the Grapes were badly affected by rust, while lower down they were almost free of it. I was consulted about the matter, and upon asking about the ventilators was told they had been opened daily, notwithstanding the prevalence of cold wind. My advice as to the exercise of caution about opening the ventilators was acted upon in the following spring, and there was no more rust.—EDWARD LUCKHURST.

PORTRAITS OF NEW AND NOTABLE PLANTS.

SALVIA HIANSA.—*Nat. ord.*, Labiatae. "A very handsome perennial, of which seeds collected in Kashmir were sent to Kew by Dr. Aitchison in 1877. He describes it as growing profusely in grassy marshes, at elevations of from 8,500 to 11,000 feet, and flowering in July and August. It was first found by Royle's collectors, sent from the Saharunpore Gardens to Kashmir, and

flowered at the Royal Horticultural Society's Gardens in 1840, whence the figure in the 'Botanical Register' was made; but neither this figure nor Royle's gives any idea of the intense sapphire-blue of the corolla. It has also been collected in Kashmir by Jacquemont and Falconer, and, as one of the most beautiful plants of that botanically rich valley, it can hardly escape the notice of future collectors. Dr. Lindley describes it as "one of the gayest of our perennials, in consequence of the striking contrast between the white and blue of its large flowers." The plant flowered in the herbaceous grounds at Kew in June of the present year."—(*Bot. Mag.* t. 6517.)

TULIPA BIFLORA, *TULIPA ILIENSIS*.—"T. biflora has been long known, but is very seldom seen in cultivation. It is spread from the Volga through the western half of Siberia. It is notable in the genus for producing normally more than a single flower. It has a woolly bulb, like *montana*, but otherwise its affinity is with *sylvestris* and *australis*. The drawing was made from a plant sent by Mr. George Maw from his garden at Broseley. T. iliensis is one of the numerous new species that have lately been discovered by the Russian explorers in Central Asia. Its alliance is close with T. triphylla, 'Bot. Mag.' tab. 6549. In their flowers and leaves these two resemble *australis*, but the stamens are like those of *Gesneriana*. The drawing was made from a plant sent by Mr. F. W. Burbidge, which flowered in the garden of Trinity College, Dublin, last February."—(*Ibid.*, t. 6518.)

ALOE GREENII.—"This is a well-marked new species of Aloe of the group *Pictæ*, which we have for some time cultivated at Kew. It was received under the name from Mr. Wilson Saunders, and this name was given to it by Mr. T. Cooper, but that it is not one of the plants which the latter collected in his travels in Cape Colony, which yielded so many interesting discoveries in this set of plants."—(*Ibid.*, t. 6520.)

STELIS BRUCKMULLERI.—Probably a native of the Mexican Andes. "This singular little Orchid resembles the green-flowered *Stelis ophioglossoides* of Swartz, a West Indian plant, figured in the 'Botanical Register' (tab. 935), but has smaller leaves and flowers, and the latter are of a purple colour and hairy inside; the bracts too are different, those of the species here figured resembling funnel-shaped cups with very oblique mouths. Like all the other species of the genus, it is of botanical interest rather than horticultural."—(*Ibid.*, t. 6521.)

LATHYRUS ROTUNDIFOLIUS.—"This very beautiful plant has been long cultivated in England, though when and how introduced is not certain. It is not described in Aiton's 'Hortus Kewensis,' nor, up to this time, cultivated at Kew; it is not included in Le Maout and Decaisne's 'Flore Elementaire des Jardins et des Champs,' which is the fullest work of the kind known to me, nor do I find it in the more accessible works devoted to English out-of-door gardening; yet I observed it last summer growing in the gardener's cottage at Lytchett, and it probably occurs elsewhere, though overlooked as too like an Everlasting Pea to be worth notice. Nevertheless it is one of the most charming plants of its kind, perfectly hardy, a free flowerer, and for the brilliancy and delicacy of its rose-coloured flowers it ought to be a favourite. Like its near ally, the Everlasting Pea, it is scentless. L. rotundifolius has a wide range; we have examined specimens in the herbarium from Roumelia, the Crimea, Asia Minor, and the Caucasus, and according to Boissier it extends eastwards to Northern Persia."—(*Ibid.*, t. 6522.)

KITCHEN GARDEN.

THE weather is now such that it is unwise to postpone protecting or lifting plants that require it. Lettuce and Endive should be lifted at once, as the keeping qualities are much deteriorated when the midribs are injured by frost. The plants must be lifted with a small ball of earth attached to each, and be placed in moist soil in frames, pits, or houses, and with ordinary attention to ventilation they will keep in good condition a long time. Too much ventilation cannot be given in mild weather, and in case of frost the coverings must be sufficiently thick to exclude it. Endive will require to be tied up or covered with some material to ensure its blanching. Celery if left too much exposed will be damaged by frost, and must not only be well earthed up but have some dry litter placed over the plants

in severe weather. Beet is impatient of frost, and should be taken up at once. In lifting and trimming be careful to avoid injuring the roots, otherwise the colour will be spoiled. To keep Beet fresh and sound until the next year's supply comes into use it should be buried beneath the surface of the soil in a cool shaded place, being covered with a little straw and soil. That for winter use can be placed in damp sand in the root house. Roots of Carrots, Salsafy, Scorzonera, and a portion of the Parsnips should be taken up and stored for winter use. Avoid trimming these too closely, placing them in narrow piles in moist sand. Take up Cauliflowers that have heads about the size of a breakfast cup, and lay them in moist soil or ashes in a frame or pit, and protect from frost, ventilating freely in favourable weather. They will afford a good supply of heads for cutting.

Complete the planting-out of Lettuce and Cabbage as soon as possible, and finish pricking out Cauliflower plants from seed beds, planting or pricking out some at the base of a south wall, particularly of the Walcheren variety, which in an ordinary season withstand frost, and are well hardened for planting out early in spring. Remove all decayed leaves from Broccoli, Brussels Sprouts, and winter greens, so as to expose and harden them as much as possible.

Frame Ground.—While the weather continues open fully expose Cauliflowers, Lettuces, Endive, and Radishes in frames, withdrawing the lights when the temperature outside is above 35°. Lettuces and Endive should be protected from heavy rains by placing the lights on, but tilting them back and front.

FRUIT HOUSES.

Pines.—Afford fruiting plants the temperature and treatment indicated in our last calendar, but in adverse weather a reduction of about 5° should be made. The fruit now appearing will be ripe when other kinds of fruit are scarce; such plants, therefore, should be afforded a good position in the fruiting department. During flowering the fruit should not be wetted. Queens do not, as a rule, start into fruit so readily as some varieties, but they may be assisted by resting the plants after they have made a growth for six or eight weeks. Plants intended to produce fruit early in the year must be treated accordingly, the temperature of the bed being allowed to gradually fall to 70°, and that of the house to 65° by day and 60° at night. Cease damping houses that are naturally moist, watering the plants only when absolutely necessary, which will not often be needed by those in fermenting beds. Ventilate at 70°, doing so liberally above that degree. Keep the lights of all Pine structures free from whatever may obstruct light.

Cucumbers.—The autumn-fruiting plants will now be in bearing, and should have a night temperature of 70°, falling to 65° in the morning, 75° by day, and 80° to 85° from sun heat. Admit a little air at the top of the house on every favourable opportunity; but it must not be done with a view to lower the temperature, but to permit the escape of vitiated air, and secure a sweet healthy atmosphere. Avoid cold currents of air, counteracting the necessity for much ventilation on account of the sun by shutting off the top heat for a few hours in the middle of the day. Avoid also sudden fluctuations of temperature, taking care that the water and soil applied to the roots are about the same temperature as the house. Cease syringing the foliage, or do it only in the early part of bright afternoons, keeping the evaporation troughs regularly charged with liquid manure. Damp the paths and walls morning and afternoon. If worms are troublesome dispel them by weak doses of lime or soot water, dusting the foliage with sulphur upon the first appearance of mildew.

PLANT HOUSES.

Heaths.—Plants potted last month will now be rooting in the soil, as when in good health they root freely at this season. Care will be required in watering; closely examine them before supplying it. Ventilate moderately day and night when there is no apprehension of frost. The plants should be kept as cool as possible without being subjected to frost, leaving the roof lights open so long as there is no danger of too great a depression of temperature. The plants can now be tied, commencing with the earliest-flowering kinds. The dead foliage must be removed from the wood, the plants being laid on their sides for that purpose, removing the old stakes carefully,

and inserting the new stakes in the same holes, so as to damage as few of the roots as possible. In tying secure green leafy shoots down to the surface of the pots. Winter-flowering Heaths coming into bloom must have a light airy situation and not be overcrowded.

Azaleas.—To have these plants flowering well and long during the spring months it is requisite that they be started into growth at different times. Plants intended for flowering late in the spring must not have their growth completed early in the autumn, or the consequence is they flower too early. Plants that have been latest in making their growth will not yet have their buds fully matured, and should be aided by a little fire heat, for whether Azaleas are early or late in starting into growth, they should always be kept in a moist warm temperature until the buds are prominent, large, and firm. The growth, from being arrested as soon as the buds are perceptible, is certain to have an effect upon the flowering, the plants never producing flowers half so well or so fine as plants which have had the bloom buds fully matured the previous season. Plants set apart for decorative or exhibition purposes should now be tied into form. A rounded cone is perhaps the best, with the height half as much more as the diameter of the plant at its base, which should always be the widest, as when Azaleas reach a considerable size they do not bloom regularly all over but at the top first, which is a result of the base not being wide enough or the strongest shoots being trained to the top of the plant instead of being kept at the base. Specimens flowering irregularly must be untied and have the thickest branches brought well down, leaving the weaker to form the head. The early-flowering Azalea *vittata elegans*, white with red edgings, is but seldom met with, which is the more remarkable, as it commences flowering shortly in a temperature a little warmer than an ordinary greenhouse, flowering consecutively for several weeks. Started into growth and the buds set early it will flower in September. Some of the earliest varieties, if their growth has been well managed, can now be placed in gentle heat, and not being excited by a high temperature their flowers will be enhanced in value for cutting. *Alba*, *amoena*, *Borsig*, *Fielder's White*, and *Narcissiflora* are the best for forcing.

Roses of the Tea and China varieties that were cut back and potted in spring after flowering, and have since then been plunged outdoors, will now be full of flower buds, and if placed in a light house with a little heat they will open their flowers. If a number of plants be treated in this way it is not advisable to bring them all into flower at once; but a portion should be placed in a north house, or where they will be kept cool without being too much saturated by the autumn rains. Roses are at no time more acceptable than in autumn, and for affording them none are better than the neglected Chinas from their continuous flowering habit; but to have these and Teas in condition to produce flowers in quantity at this time they must have had liberal treatment through the summer. When they have not been well supplied with liquid manure the blooms they will produce will be few; but being kept free from insects they will afford useful flowers for cutting until January.

Calceolaria seedlings must not be allowed to become crowded in the seed pans, but should be pricked off as soon as they are large enough, and from the pans they can be transferred to small pots before they become drawn, keeping them in all stages near the light, and not where they will be exposed to a dry atmosphere. Three parts of turfy loam, one part of leaf soil, and one of thoroughly decayed dung with a little sand, is a suitable compost.

Rochea falcata when out of flower should have the main stem cut back, and the leaves removed carefully with a sharp knife. Insert them singly in small pots, well drained and filled with sandy peat; or they may be inserted round the sides of 5 or 6-inch pots, and afterwards be transferred when rooted singly to 3-inch pots. They may be placed on a shelf near the glass in a temperature of 50°, where they will soon root, the soil being kept just moist, for if kept wet the leaf cuttings will decay. It is one of the brightest of autumn-flowering plants, and is deserving of more general cultivation.

Chrysanthemums should be under cover, it not being advisable to house them too early, as if the flowers are not well advanced before the plants are placed indoors they are liable to become drawn and affected with mildew. The flower buds should be thinned out when

large enough. Supply the plants with liquid manure, and keep them tied out as required.

Clianthus Dampieri should have a temperature a little higher than an ordinary greenhouse, keeping it near the glass and away from cold currents of air. If the plants are in small pots shift with the ball entire, not even removing the crocks, pressing the soil down carefully. It succeeds best in lumpy peat with an admixture of charcoal.

Cinerarias requiring a shift must be attended to. The second lot may now be transferred to the pots in which they are to bloom. To flower satisfactorily at this season a temperature of 50° is necessary by day artificially. The temperature for the ordinary stock should be kept at 40° to 45° by day artificially, admitting air at the latter, fully at 50°, and closing at that degree. Do not be in a hurry in applying fire heat. In damp weather a little fire heat will be necessary to expel damp, air being admitted freely, but avoid a close warm atmosphere at night, or indeed at any time, as it is injurious to every greenhouse plant at this season. The night temperature should be kept at 40° to 45°, but frost being excluded the safety of the plants is insured. Watering should be done in the morning, and the supply regulated according to the requirements of the plants, keeping them rather dry than too wet.

Bouvardias.—To have the full flowering capabilities of these plants they require in the winter time plenty of heat and light, the temperature 60° to 65° at night, and an increase of 5° to 10° in the day. An application of liquid manure will assist their growth and flowering. Spring-struck plants grown on through the summer are the most suitable, they being now in 7 or 8-inch pots. *Humboldti corymbiflora* has large white flowers like a *Stephanotis*, the bunches being large. The *Bride* is very fine; *Bridal Wreath*, *candidissima*, *jasminoides*, *longiflora*, and *Vreelandi* are the best whites; *Brilliant*, *elegans*, and *leiantha* are good scarlets; *rosea oculata*, *blush*; *intermedia*, *pink*; *umbellata*, *rosy blush*; and *flava*, *pale yellow*.

NOTES ON VILLA AND SUBURBAN GARDENING.

FLOWER GARDEN.

Filling the Beds for the Winter.—When clearing the beds of their summer occupants all such plants as *Cineraria maritima*, *C. acanthifolia*, *Golden Pyrethrum*, *Golden Thyme*, *Golden Japanese Honey-suckle*, *Stachys lanata*, *Beet* (to be used in common with those small plants saved in the kitchen garden as advised), *Ajuga reptans rubra*, *hardy Sempervivums*, and *Sedums*, and any other hardy kinds, should be carefully saved and worked in afresh. With these may be associated small *Aucubas*, *Thujas*, *variegated Hollies*, *Retinosporas*, *Yuccas*, *variegated Euonymuses*, and other easily-moved and frost-enduring plants. These may be arranged either in groups and rings, or be dotted about the beds according to their respective heights and colours; the above-mentioned bedding plants in the first instance to be used for edgings, and in the latter for a groundwork—that is to say, should fill up the intervening spaces, and also form the edgings. Small shrubs suitable for bedding can be obtained at a cheap rate, and will be available for years, the frequent removals checking luxuriant growth. Much may be done without them, especially if a quantity of *Forget-me-not*, *Limnanthes Douglasii*, *Collinsia bicolor*, *Silenes*, *Wallflowers*, and *Daisies* have been prepared. The *Pyrethrum* is particularly useful, as it can be employed to form designs as in the summer bedding, filling in the outer spaces rather closely with *Ajuga*, *Daisies*, *Stachys*, *Limnanthes*, and *Silenes*, and those spaces nearer the centre with *Beet*, *Collinsia*, *Cineraria*, *Forget-me-not*, and *Wallflowers*. Suitable for dotting are small pieces of *Iris foetidissima variegata*, *golden variegated Lilium candidum*, and *Yuccas*. The *Pyrethrum* and other bright-coloured plants should be employed as much as possible next to the turf, dull colours failing in effect; yet *Sempervivums* are very suitable for fringing the raised beds.

A good arrangement consists of an edging of *Pyrethrum*, next this *Ajuga*, behind this *Stachys*; the remaining space, however large, consisting of *Forget-me-not*, and dotted among this either the *variegated Iris* or *Tulips*. Another mode may be as follows:—An outer line or ring of *Golden Thyme*, next either *red Daisies*, *Silenes*, or *Beet*; the remaining space being filled with *Cinerarias*, among which may

be dotted either *Hyacinths* or the *Spanish Iris*. A third may consist of a broad edging of either *red Daisies* or *Ajuga*, among which are dotted either *Crocuses* or *Snowdrops*; next another broad band of either *Limnanthes*, *Stachys*, or *pegged-down Cinerarias*, with *Hyacinths* interspersed, filling up the centre or back as the case may be with a groundwork of either *Collinsia*, *Beet*, or *dark Wallflowers*, among which might be dotted either *Narcissuses* or *Tulips*. Many somewhat similar arrangements, if well carried out with good plants and bulbs, should the winter prove of average severity, will eventually prove more effective and pleasing than the summer bedding. Carpet bedding, where the outlines of the designs have been formed with hardy plants, notably the *Pyrethrum*, and the groundwork formed with a hardy plant such as the common *Stonecrop* or *Sedum glaucum*, may easily be made effective by substituting *Ajuga* for the *Alternantheras*, *Beet* for the *Iresines* and other rather tall plants, and the *Stachys* for lighter-coloured medium-height plants. *Iris* (variegated), *Golden Lily*, *Yuccas*, and miniature variegated and *Conifers* are well adapted for “dotting.” With these materials carpet coloured beds for the winter may yet be formed, and will look well from the commencement.

Planting Bulbs.—Readers of this column who intend to plant bulbs extensively are referred to the instructive remarks on the subject by “A STATION MASTER” on page 370 of the Journal. The only objection to beds filled with bulbs as there recommended or otherwise is their bareness during the early part of the winter. This bareness may be obviated by covering the beds with small neat branches of evergreens as the bulbs are placed in. *Variegated Hollies*, *Aucubas*, *Berberises*, and *Ivies* of the tree type are very suitable, and should be arranged in bands and carefully pressed into the soil so as not to injure the bulbs; they will retain their freshness for a long time, and serve to protect the bulbs.

GREENHOUSES.

Potting Bulbs.—In continuation and conclusion of remarks on this subject, commenced on page 379, mention ought not to be omitted of *Amaryllis formosissima*, *Peacock Iris*, *Tropæolum tricolorum*, and *Cyclamen persicum*, as all are included in most advertised collections. The two first may be potted either singly in 4-inch pots, or three can be placed in 6-inch pots. The *Tropæolum* if moderately strong may receive an 8-inch pot, and the *Cyclamen* a 4-inch pot, or still larger if of good size. The bulbs of the first and the fleshy roots of the others should all be about three parts buried in the soil. Care must be taken to pot the tubers of the *Tropæolum* the right way upwards, and also to avoid breaking its delicate thread-like growth when it starts.

After-treatment.—The pots containing the six first-mentioned kinds—viz., *Hyacinths*, *Narcissuses*, *Tulips*, *Crocuses*, and *Snowdrops*, should be placed on a cool dry bottom in the open, and be completely covered to the depth of 5 or 6 inches with either sifted ashes, sawdust, or cocoa-nut fibre, the aim being to have the pots well filled with roots previous to the commencement of any top growth. No watering will be necessary unless the soil employed be very dry. The remainder may be either placed in a cold frame or on a greenhouse shelf, and will require but little water for a time. It may not be out of place to suggest the advisability of purchasing either the general collections as advertised, or collections of different kinds, leaving the selection of varieties to the vendors, as this will be found to be by far the most economical procedure.

TRADE CATALOGUES RECEIVED.

James Veitch & Sons, King's Road, Chelsea.—*Catalogue of Roses, and List of Iris Kämpferi Varieties*.

Charles Turner, The Royal Nurseries, Slough.—*Catalogue of Roses and Fruit Trees*.

Robert Parker, Exotic Nursery, Tooting, Surrey.—*Lists of Pyrethrums and Potentillas*.

Osborn & Son, Fulham, London, S.W.—*Catalogue of Plants, Shrubs, and Trees*.

Ormiston & Renwick, Melrose, Roxburghshire.—*Catalogue of Forest and Ornamental Trees*.

J. Cheal & Sons, Crawley, Sussex.—*Catalogue of Trees and Shrubs*.

Henry Merryweather, The Nurseries, Southwell.—*Catalogue of Fruit Trees*.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Addresses (A Deal Correspondent).—Write to Messrs. William Paul & Son, The Nurseries, Waltham Cross, Herts. (H. L. B. L. B.).—We are unable to answer your question. If you write to Messrs. T. Green & Sons, Smithfield Iron Works, Leeds, they will perhaps be able to give you the information you require.

Evergreen Screen Plant (Type).—There is none equal for your purpose to the Ivy; and *Hedera Regneriana* has fine, large, smooth, deep green foliage.

Large Gooseberries (Idem).—Amongst the largest are London, red; Catharina, yellow; Shiner, green; and Antagonist, white; but if you intend exhibiting it will not be safe to grow one variety only in each section.

Nomenclature (Old Subscriber).—We are obliged by your letter. We took special means to obtain accurate information regarding the Melon, and this we thought was all you needed.

Ferns (S. R. S.).—There is no work specially devoted to the Ferns you mention, but you will find much of the required information in the "Greenhouse Manual," published at this office, price 9d., or post free 10d.

Pears for Wall (R. B.).—The following good varieties usually ripen during December and January:—Glou Morceau, Knight's Monarch, Ne Plus Meuris, Winter Nelis, Zéphirin Grégoire, and Huyshe's Prince of Wales. They will succeed in your district.

Blisters on Willow (W. Begbie).—These blisters or galls are the work of several small flies in the genus *Cecidomyia*. They are gnat-like creatures, and their tiny wings shine with prismatic colouring under a magnifier. But it is not easy to rear them, for they are much infested by a parasitic fly still smaller, the larva of which starves or devours the one that is first tenant of the gall. Finally these galls become lodging places for sundry Acari or mites.

Angle for Vinery (M. M.).—Whether the house be a lean-to or span-roof the best angle for the roof is 45°, but for very early forcing steeper-pitched roofs were formerly employed. The angle must be calculated from the base, or the slope which it makes with the base; the base line and height in the centre of a span or back wall of a lean-to being equal, calculating from the top of the upright side or front lights when the angle of elevation is 45°.

Training Vines in Pots (A Young Gardener).—The canes being intended to be trained spirally around stakes they may be trained before starting, as it will tend to arrest the flow of the sap to the extremities, the point of the cane being kept rather lower than the other part until the eyes have broken along the cane, when it may be elevated. If for a trellis the canes should be depressed until they have the buds well broken, and then be secured to the trellis. Muscat of Alexandria is not a suitable Grape for early forcing, but succeeds if not started before January and afforded plenty of heat.

Keeping Pears and Apples (F. J.).—Your room with trellised shelves will answer for keeping fruit, although there is no means of affording artificial heat, the fruit being laid on clean dry straw and covered with straw in severe weather so as to exclude frost. Do not remove the loose bark on the stems of outdoor Vines until spring, and not then unless it is necessary to dress the rods with a composition to prevent mildew and insects appearing.

Wintering Pelargonium Cuttings (J. B.).—The house in which Roses are forced will not be too warm, providing you can afford the Pelargoniums positions near the glass and ventilators so as to secure sturdy growth; but if they must be kept at a distance from the glass they will become drawn and weakly, and be proportionately deteriorated for bedding. The room without a fire would be most suitable, removing them during severe weather to a kitchen or other place where they would be safe from frost. It would not answer to place them in a cupboard or cellar for any length of time. For the Pelargonium cuttings to succeed they should be placed in a house at this season with a minimum temperature of 55°; failing this you had better not prune the plant until the spring, when the cuttings will strike readily.

Forcing Seakale (Beginner).—You give us no data as to the proposed method of forcing, but we presume it is by dung or other fermenting materials. Take up the plants with all the roots possible, and place them so that about five crowns can be covered with an ordinary Seakale pot. The crowns should be, as grown, level with the surface, and should be placed so as to be covered with fermenting materials by the 1st of December to have heads for cutting at Christmas. If forced in a house the temperature should be 55° to 60°, and introduced at the time named. The best time to topdress an indoor Vine border is as soon as the foliage shows indications of falling. The sooner it is done now the better. Liquid manure should not be given to Vines that have Grapes hanging, nor should it be applied when they are at rest, but during growth.

Hyacinths (Old Subscriber).—If you order the "earliest varieties" pot them at once in 5-inch pots, covering the pots 6 inches in depth with cocoa-nut fibre refuse, leaf soil, or ashes, and when the pots are filled with roots and growth is apparent place them on the shelf of a house having a temperature of 50° to 55°. you will, we think, have the plants in flower by the time required. Winter Aconites require the same treatment as to potting and plunging, but must not be placed in a warm house. The best mode of obtaining good pots of Snowdrops is to take up some established clumps of the single variety, pot them, and grow them on the shelf of a light greenhouse. If you could bury the Hyacinths in a heap of leaves that are very slightly heated the growth would be accelerated, but much heat is dangerous.

Mildew on Roses (E. C.).—You had better prune the plants before you place them in the house or frame, then most or all of the affected leaves will be removed; then paint the stems with sulphur mixed to the consistency of paint with a strong solution of soft soap and a little tobacco water. A little sulphur falling on the soil is not injurious. If your plants when growth commences are regularly syringed with the soft soap solution as recommended by Mr. Barduey they will be kept free from mildew. We have seen a fungus resembling a cobweb spread over the surface of cocoa-nut fibre refuse in a close, damp, slightly heated pit; but in a well-heated propagating house, or when the material is exposed to the air, it is very rare that any fungus is seen on it to do injury. The other subject to which you refer shall have our attention.

Rose for Greenhouse (Bradford Reader).—A Maréchal Niel or Gloire de Dijon Rose would succeed in your house provided the stem was protected from the heat of the cistern. The soil would need to be good, and copious supplies of water would be required in the inside border. In all probability a Rose would do equally well, and perhaps better, worked on a standard Briar and planted at the back of the house outside, the growth being brought through the wall above the cistern; in that case the stem of the Briar would need protection with haybands. A Vine—Black Hamburg—would grow as well as a Rose in the inside border, as shown in your sketch, but its stem would need protecting from the excessive heat of the cistern. Cannot you plant in the front of the house and train the Vine up the roof? The Rose may be planted in November, and a Vine may be planted at the same time, but if it is in a pot spring planting is preferable just as the buds are commencing growth.

Overcropping Vines (J. E.).—Overcropping is a relative term. We have seen Vines decidedly overcropped when not bearing more than half a pound of fruit to each foot of rod, while other Vines were not overcropped with three times that weight of fruit. If your Vines are really healthy, with active roots, short-jointed wood, and thick leathery foliage, the crop you name is not by any means heavy. How many rods have you in the space of roof mentioned? If the rods are closer to each other than 3 feet, and the laterals from them are not more than a foot apart, your Vines are overcrowded, and the leaves will not be well developed, as they have not been fully exposed to the sun, nor will the wood be matured. Under these conditions the Vines will not be really healthy, though they may grow luxuriantly, and are therefore not able to perfect their crops. We suspect we have suggested the chief cause of your Grapes not colouring, and the evil would be aggravated by the insufficient ventilation to which you allude.

Myrtle Diseased (Richmond).—The leaves sent to us appear to be injured by the ravages of thrips, though the evidences of their presence are obliterated by washing with water. The leaves of the tree, if at all like those sent, will all fall. Syringe the tree with a solution of 4 ozs. of soft soap dissolved in a gallon of water, to which is added a quarter of a pint of tobacco water. The tree being thoroughly wetted, both on the under and upper side of the leaves, allow the mixture to become dry upon the tree, and then wash it off with water at a temperature of 120°. In a week repeat the washing or syringing with the tobacco water and soft soap solution, and syringe the tree twice a day afterwards for a week or ten days with water, keeping the soil no more than moist, as the demands of the head will be at a minimum, and avoid a wet state of the soil through the winter.

Tomatoes for a Cool House (R. G. M.).—With us as with you, Hathaway's Excelsior proves a somewhat lighter cropper than either Dwarf Orange-field or the Old Red, but the fruits are of better appearance and superior quality. As you prefer weight to fine quality and shape you will certainly do well to either grow more of the above older varieties, or to add Earley's Defiance and a few for trial of Conqueror. Earley's is apparently a good selection of Large Red (or as you have it Old Red), and is a heavy cropping variety, very suitable for a cool house. The colour of the Conqueror is a glossy vermilion, in the way of but superior to that of Acme and Vick's Criterion, neither of which were liked in the markets at one time. This prejudice may by this time have been overcome, at all events the Conqueror is of the three the most likely to effect this favourable change of opinion. It is certainly a heavily-cropping, easily-grown, early variety.

Seeds for Garden (W. W.).—Your question as put is almost unanswerable, as so much depends on the nature of the soil and the system of culture pursued. Perhaps the following table of "seeds required for a garden of 1 acre," extracted from the *Gardeners' Year Book*, will be of service to you; the quantities can be increased or diminished according to the extent of ground at your disposal:—Peas, 5 quarts; Beans, 2 quarts; Kidney Beans, 1 pint; Scarlet Runners, 1 pint; Cabbage, early, 2 ozs.; Savoy, 1 oz.; Brussels Sprouts, 1 oz.; Cauliflower, 1 oz. in two varieties; Broccoli, 2 ozs. in four varieties; Borecole, 2 ozs.; Cabbage, Red, ½ oz.; Kohl Rabi, ½ oz.; Onions, 4 ozs.; Carrots, 2 ozs.; Turnips, White, 2 ozs.; Turnips, Yellow, 1 oz.; Celery, ½ oz.; Spinach, ½ pint; Beet, Red, 1 oz.; Beet, Silver, ½ oz.; Leek, 1 oz.; Parsnip, 2 ozs.; Salsify, ½ oz.; Skirret, ½ oz.; Scorzoneria, ½ oz.; Endive, 1 oz.; Lettuce, 2 ozs. in two varieties; Radish, Long, ½ pint; Radish, Turnip, ½ pint; Mustard, ½ pint; Cress, ½ pint; Parsley, curled, ½ oz.; Potatoes, early, in two sorts, 1½ bushel; Potatoes, late, in two sorts, 2 bushels; Jerusalem Artichokes, 1 gallon; Garlic, ½ lb.; Shallots, 1 lb.; Sweet and Pot Herbs, of sorts, 1 oz.; Rhubarb, of sorts, 25 roots. To the above add one packet of each of the decorative and garnishing plants you name in your list.

Apples for Market (P. Gruel).—In reply to your request for names of "two hundred late sorts of dessert and kitchen Apples of good size and appearance, in use from October to May for market purposes," our reply is that we decline the responsibility of recommending anyone to plant so many varieties for the purpose in question. We presume you want two hundred trees, but you do not say so, and you could not possibly make a greater mistake than to plant so many varieties. Instead of naming two hundred we name fifty varieties, thirty for culinary and twenty for dessert purposes, that are likely to be profitable; but if we were planting as many trees as you propose we should not include more than half the varieties here named, or at least should only have one tree each of many of them to prove their adaptability to the soil and district. The first half or two-thirds of the varieties named in each section are the most likely to prove satisfactory, and those we should plant in the greatest numbers. **Dessert.**—Cox's Orange Pippin, King of the Pippins, (Golden Winter Pearmain), Golden Reinette, Scarlet Nonpareil, Court Pendu Plat, Scarlet Pearmain, Barcelona Pearmain, Lodgemore Pearmain, Baxter's Pearmain, Wanstead, Sturmer Pippin, Nonpareil, Dutch Mignonne, Herefordshire (Royal) Pearmain, Aromatic Russet, Claygate Pearmain, Winter Pearmain, Scarlet Crofton, Melon Apple, and Mannington's Pearmain. Many good dessert Apples are very small, but the above possess either size, colour, or quality in combination with free-bearing properties. **Culinary Apples.**—Warner's King, Dmelow's Seedling (sold as Wellington in the south), Beauty of Kent, Ecklinville Seedling, Alfriston, Stirling Castle, Round Winter Nonsuch, Striped Beefing, Brabant Bellefleur, Gooseberry Apple (grown largely for the London market), Fearn's Pippin,

Mère de Menage, Loddington Seedling, Waltham Abbey Seedling, Norfolk Bearer, Frogmore Prolific, Northern Greening, Kentish Fillbasket, Gloria Mundi, Castle Major, Tower of Glammis, Rymer, Sleeping Beauty, Yorkshire Greening, Forge, Bedfordshire Foundling, Winter Greening, Winter Codlin, Lady Henniker, and Cobham.

Cucumbers and Tomatoes (C. S.).—Your two long span-roofed houses with ordinarily skilful treatment ought to be remunerative whether the crops grown be either Cucumbers or Tomatoes. We are inclined to think you have an insufficiency of bottom heat for very early, and in fact the main crop of Cucumbers, as there ought at least to have been two pipes—say a flow and return. Taking all things into consideration, we should advise the planting of the warmest side of one house before the Tomato plants are much rootbound, and thereby receive a severe check. Any surplus plants may be fruited profitably, either singly or in pairs, in 12-inch pots; stake the plants and place them on the opposite side of the house till the space is wanted for plants obtained from a January sowing, by which time a crop will be set on them, and failing a better position may then be placed on your wide pathway to ripen. If there is any difference devote the warmest house to the Cucumbers, and plant the warmest side of this with January-raised seedlings, and when these are well established raise more plants for the opposite side. The latest planted in both instances will very probably be found most profitable “in the long run,” as the growth will be stronger and cleaner owing to the increase of solar heat (which ought to be taken advantage of by closing early), and a corresponding decrease in artificial heat. If cropped and treated rationally the plants ought to continue bearing till far into the summer. We should, however, advise you to raise another batch of plants of both Cucumbers and Tomatoes to follow those first planted, as being more likely to produce heavier and superior crops to those usually obtained from renovated old plants. When preparing your pits for either kind first fill the bottom so as to quite bury the pipes with broken bricks or something similar, over these place a layer of turves grass downwards, and failing this substitute rough and rather fresh stable manure; on this place mounds of rough and rich turfy soil 3 feet apart for Cucumbers, and a ridge of similar soil for Tomatoes, a plant of the former to each mound. The earliest Tomatoes may be planted 15 inches apart, and the more vigorous successional plants 18 inches apart. In all instances topdress frequently with rich rough soil; water often, sometimes with liquid manure, and always of the temperature of the house; attend well to the disbudding of the Tomatoes and the stopping of the Cucumbers, and avoid heavy cropping. When replanting all fresh soil need not of necessity be used, but it is advisable to work in some, and also a sprinkling of one of the artificial manures as advertised; sprinklings of the latter may with advantage be substituted for the liquid manure providing it is not used to excess. Early Tomatoes will do well in a temperature of from 60° to 65° by night, increased to 70° to 75° by day; and if any difficulty is experienced in setting a crop maintain a drier atmosphere for a few days, open the top ventilators early, and when the pollen is dry, which would be towards mid-day, lightly brush the flowers with a camel's-hair brush. The Cucumbers should receive about 5° higher throughout, a more moist atmosphere also being maintained. You should carefully read the remarks on Cucumber culture by Mr. Stephen Castle on page 369.

Names of Fruit (A. Ridgway).—The Apple is Pine Golden Pippin. (*Henry Riches*).—1, Not known; 2, Dumelow's Seedling; 3, King of the Pippins; 4, Royal Russet; 5, Blenheim Pippin. (*D. C.*).—1, Beurré de Capiaumont; 2, Comte de Lamy; 3, Figue d'Alençon; 4 and 5, not known; 6, Maréchal de Cour; 7, Groom's Princess Royal. (*C. W. H.*).—1, Wormsley Pippin; 2, Rhode Island Greening; 3, Herefordshire Beefing; 4, Reinette de Canada; 5, Royal Reinette; 6, Christie's Pippin. (*R. O.*).—1, Not known; 2, Newtown Pippin; 3, Adam's Pearmain; 4, Braddick's Nonpareil; 5, Sturmer Pippin; 6, Shepherd's Fame. (*W. H. Divers*).—1 and 2 we do not recognise; they may be local varieties or seedlings, and are very sour. No. 3 resembles Calville Blanche. (*F. O. M.*).—No. 1 is Cockle Pippin, and No. 2 Fearn's Pippin.

Names of Plants (J. Smith).—1, *Aster novæ-angliæ* var. *roseus*; 2, *A. Curtisii*; 3, *A. novæ-angliæ* var. *pulchellus*; 4, *A. dumosus*; 5, *A. ericoides*; 6, *A. Tradescantii*. (*W. C. B.*).—1, *Adiantum Capillus-Veneris*; 2, *Adiantum assimile*; 3, *Panicum plicatum variegatum*; 4, *Gymnogramma peruviana argyrophylla*; 5, *Selaginella stolonifera*; 6, The specimen was insufficient for identification. (*J. R. Wraybury*).—1, Apparently imperfect specimens of *Goniophlebium subauriculatum*; 3, *Pteris longifolia*; 2 and 4 were too much crushed to be recognisable. (*E. C. O.*).—*Medicago echinus*. (*H. H. T.*).—*Francoa ramosa*. (*H. A.*).—*Malva moschata*.

POULTRY, PIGEON, AND BEE CHRONICLE.

ROTATION FOR CROPPING LIGHT SOILS.

(Continued from page 382.)

IN concluding the subject of rotations for light soils we propose more particularly to refer to two descriptions of land which we have not yet touched upon—viz., the light thin weak land, often found at a very high altitude, and overlying the great oolite or Bath freestone rock, and known as “stone brash,” and which is found in particular districts, such as the elevated plains like those in Gloucestershire called the Cotswolds, and in various other counties, especially in the western and north-western portions of the kingdom. Although these soils are very thin, yet they are dry in the winter, affording excellent lying for sheep—in fact, upon these soils are to be seen some of the finest long-woolled

sheep, in proof of which are the Cotswolds, taking their name from the district of which they are natives. The other soils, which we feel bound to recognise as being of the greatest importance of all the light soils, are the gravels, in proof of which we find them when favourably situated as to climate, &c., making a higher rent than any other light land. They are met with in nearly all the counties to some extent, but more particularly we find them in the south and south-eastern districts, where they are called the home of the fat sheep, lambs, and bullocks, which supply the metropolitan and other large town markets with some of the choicest and best qualities of meat raised in the kingdom. Now, these gravels are found occurring here and there in the vales on the side of river courses, and at the mouths of rivers, and not unfrequently skirting the seaside. We have noticed that these gravels are generally situated next to the water meadows in most of the districts where the mixed soils occur, and this circumstance goes far to characterise the style of management and rotations which prevail in the tillage of such land.

We will, without further enlarging upon the subject, proceed to give the rotations adopted, and which we recommend, taking first the “stone brash” soils; and for the purpose of illustration we will again take a farm of 450 acres, situated on the open plains without downs or meadows, because in the absence of these we must apportion a certain area for Saintfoin, Lucerne, &c., for it must be remembered that these soils do not always answer in permanent pasture or down so well as chalk soils, therefore in arranging our rotation 50 acres must be in Saintfoin, &c. Our rotation will be as we recommend it, five-course—viz., 1st, Wheat; 2nd, Barley or Oats; 3rd, green crops and roots; 4th, Barley or Oats; 5th, Clover and Grass. If, however, an extra number of sheep are required to be kept a large flock will require a more extensive provision of green food, in which case the rotation should be—1st, Wheat; 2nd, green crops and roots; 3rd, Lent corn; 4th, Clover and Grasses; 5th, old lea. We will take the first-named rotation as adapted for a flock of a moderate size and a large lain of cereals. First course Wheat, 80 acres, dunged and sown at one ploughing and pressing. Second course Lent corn, 80 acres, autumn-fallowed or surface-cleaned, in order that the corn may be sown early in the spring, and this is of leading importance on such dry soil. The Lent corn, however, should be manured by artificials, say 1½ cwt. of Peruvian guano and 2 cwt. bone superphosphate per acre, applied by the drill with the seed. In case, however, of any portion of this lain being extra foul it should be pared and burned in the autumn; it would then require no artificial manure, as the ashes would be quite equal to produce an abundant crop of either Oats or Barley, but more especially drege, because in case the crop should be laid or lodged it would not injure the quality of the grain so much as it would a crop of Barley. Third course green crops and roots, 80 acres, of which 40 acres should be seeded with Rye, Trifolium, and Vetches in certain proportions upon the cleanest land, and the foulest to be autumn-fallowed for Swedes, Turnips, Thousand-headed Cabbage, or Rape. The same sorts of roots will also be grown after the green crops, as Mangolds, Carrots, &c., do not usually succeed as a rule upon the high cold hills. Fourth course 80 acres, 50 acres of which may be seeded for Barley, the remaining 30 acres to be seeded with drege after the latest feeding of roots, which should be cleared off by the 1st of May at the latest. Fifth course 80 acres, to be seeded in the Lent corn; 40 acres with Red Clover, Alsike, and Giant Saintfoin; and 40 acres with Dutch Clover, Suckling, and Pacey's Perennial Rye Grass, these seedings to be reversed at the next rotation. This course of cropping is better adapted for a dry or wether flock than for breeding ewes, because greater numbers can be kept for the feeding off roots in good time for Lent corn, and a lesser number for grass feeding in the summer months. The second rotation as above named, and suited

for a large flock of breeding ewes, is also a five-course, and will be cropped as follows:—First course, 80 acres of Wheat after Clover, and part Turnips fed off; second course, 80 acres, green crops in part, and followed by roots; third course, Lent corn, 80 acres, part Barley and part drege; fourth course, 80 acres, seeded half with Clovers and half with grasses, as before stated; fifth course, of 80 acres old lea, will be 40 acres of Clovers, to be cut for hay or fed by sheep; and 40 acres of grasses, to be fed off until midsummer, then ploughed-up and seeded for Turnips, to be fed off by sheep eating cake, &c.

We now come to the most interesting and important courses of cropping adapted for the gravel soils, much of which, especially as they are for the most part situated in the south and south-eastern districts, in a climate favourable not only for the growth of full crops of cereals, but famous for the abundant root crops, which as a rule are grown upon them. The exceptions are those gravels having a hard conglomerate of gravel, like concrete, just under the plough, which, however, when broken through by the steam power subsoiler generally becomes a useful porous soil. The four-course or old Norfolk rotation generally prevails, and all things considered we cannot advise any other rotation, except a deviation, which will be explained, but still leaving it a four-course. In order to describe it we will again assume the farm to be 450 acres in extent; the pasture land being 50 acres, leaves for cultivation 400 acres. The course is—first, Wheat of 100 acres, sown out of Clover lea, and yard dunged, one half of which being laid out upon the young seeds in the previous winter or early spring months, the other half being laid out immediately before ploughing and pressing for Wheat. The object of this arrangement is to have the dung when laid on in a fresh and valuable condition. After Wheat comes the second course of 100 acres for green crops and roots, and when these soils are free from couch, which they are usually, 20 acres would be after harvest in Italian Rye Grass, having been seeded in the Wheat at spring time. This furnishes abundance of food for ewes and young lambs up to Christmas; it is then ploughed deep and pressed. After harvest 10 acres of Rye is sown, 20 acres of Trifolium (two sorts), and 20 acres of early and late Winter Vetches. The root crops will follow the 50 acres deeply ploughed after Italian Grass, which will be cropped with 20 acres of Mangold and Carrots without ploughing the land, but only using the scarifier to keep it clean and moist, and no dung to be applied, only artificial manures with the drill. After feeding off the Rye, Trifolium, and Vetches, Swedes and Turnips will be sown as fast as the land is cleared, and sowing Swede seed up to the 20th of June. Common Turnips after that date. This also will be dressed with drill manure only. Third course 100 of Wheat, Barley, and Oats or drege in the following proportions in a favourable season—30 acres of the land cleared early to be Wheat, 30 acres for Barley, and 40 acres for White Oats or drege. This should be sown not later than the 1st of May, as the root land, when a full winter flock of early ewes and lambs, both of horned Dorsets or early Downs, will be nearly or quite all sent to market, both lambs and ewes likewise, because we have seen it done many years in succession.

This rotation is neither more nor less than growing large crops of food in summer and consuming them chiefly in the winter and spring, because the bullocks in the boxes are provided for by one-third of the root-crop pulled away, the remainder fed off by the earliest and best sheep that can be bought, and eating both cake and Beans during the whole time; the young cattle in winter and spring receiving Rye, Trifolium, Vetches, and Clover, maintaining them in an improving and probationary state until they go into the boxes for winter feeding. The fourth course of 100 acres will be Clover, 50 acres of broad and Alsike, and 50 acres of Dutch Trefoil and Suckling mixed, to be reversed in the next rotation. The Clovers will be cut for hay in part, and cut green for feeding cattle under cover on the other part. The Dutch, &c., will be cut for lamb hay, which is the only hay really adapted for them, being very soft and fine. Under this system very few sheep will be kept in summer, and these being some tegs or ewes to take ram early for the winter feeding. We have to name another variation in the four-course, for when the land is in high condition, a large quantity of cake, &c., having been consumed, the course may be somewhat altered, particularly after the land has been marled, or clayed and chalked, to give it a little more staple, 10 acres of the Red Clover lain may be cropped with early Potatoes instead, and the same quantity with winter, not spring, Beans; and also 10 acres of early Peas to be picked early for market if situated near towns, otherwise for feeding lambs, &c. The Wheat crops on this soil and rotation may with advantage be the best white sorts, such as Essex, Rough chaff, Champion, and Chidham.

WORK ON THE HOME FARM.

Horse Labour is now chiefly employed in preparing for and drilling

of Wheat, but on the warm dry soils the seed time is often deferred to the end of November and early part of December; for it is frequently found that during the dry weather, like that which has prevailed for some time past, the horse labour can be employed with advantage in continuing the work on the autumn fallows. The home farmer may be assured that it is best to make the most of this work during suitable weather in the autumn, for there is always more or less uncertainty in obtaining favourable weather for cleaning the land in the spring months; besides which, every period brings its labour required into prominent notice. It is therefore well to make available the first opportunity by fallowing and clearing the stubbles in the autumn. This idea cannot always be carried out upon the cold hill farms, nor yet on flat, strong, and low-lying land, for October is the best seed time for Wheat upon both these soils. Carting and storing the Mangolds and other root crops will afford partial employment for some horses. It should, however, be a matter of foresight by the home farmer as to whether the roots will all be required at the farmstead, for unless that is the case hand labour only need be employed in heaping and pitting the roots in the field where they grew, and where they will be fed by sheep on the land. In the event of any portion being required for cattle in the sheds and boxes the roots may be carted to the premises at a later period when the Wheat has all been sown and the horses more at leisure. If any hindrance to the ordinary horse labour of the farm should arise some of them may be employed in collecting earth from the roadsides, banks, and borders of the fields, &c., and made up into an elongated heap with cone-shaped top, and covered with bavons or hedge trimmings, or anything which will keep the earth dry. It will then be ready at any time for breaking down and screening in readiness for being used at the bottom of the cattle boxes, pig pens, &c., for absorbing the liquid manure and keeping the animals healthy at the same time. For many years we in our practice used over a hundred cartloads per annum made into manure by the cattle, and the home farmer must bear in mind that one cartload of saturated earth as above stated is equal in manuring value to two loads of straw-made manure.

Hand Labour.—Trenching in the meadows, hedging and ditching, banking, &c., will be going on in the enclosed districts, also the cutting and converting of the underwood in the woodlands and rows may now be done to advantage. The land, too, as fast as the Wheat is sown upon the heavy lands, should be carefully water-furrowed, and where there is but little fall care should be taken to excavate the bottom of the water furrows, not only deep enough to clear out the land furrows, but to deepen them sufficiently for the water to fall into the ditches of its own gravity. This, however, cannot always be so correctly done; it is therefore the best plan to look at the work again after heavy rains, for accumulated water may then be let off. Shepherds in every district have now important work to perform. The fatting sheep will still be folded upon Turnips or Cabbages, receiving half a pound of oilcake and a quarter of a pound cracked Beans each per day; where, however, the Beans are omitted the best Clover hay should be supplied in moderation, and increased as the season advances. The Hampshire down ewes in most instances will by this have the rams removed from the flock. The long-woolled flocks will still require the rams to remain with them for another month or more from this time, because the lambs will not be required to fall until the spring grass is nearly or quite ready for the ewes. The horned Dorset and Somerset ewes are now lambing fast—at least, all the best and earliest flocks. It is a most interesting sight to all who take an interest in this breed of sheep. For a long number of years it was our pride and our pleasure to possess them; therefore we are induced to say that we consider a well-bred flock of these animals, with numerous twin lambs at their side, is one of the most charming and entertaining objects to be met with in the breeding and rearing of sheep stock. We can therefore recommend them to the notice of the home farmer, where the soil and climate is dry and favourable, both for profit and their ornamental appearance in the parklands and pastures belonging to noblemen and gentlemen, and we have generally found that they have been pleased to see and possess them as part of the sheep stock of the estate. As fast as the lambs arrive we place the ewes and lambs upon Italian Rye Grass growing in the Wheat stubbles, which we sow on the Wheat in the spring, because we have found that the ewes will give more milk on this grass than when feeding on any other food; in fact, we have on some occasions sold fat lambs at Christmas of the best quality when they have had no other food, either ewes or lambs. Cattle of all ages which are kept as either store or dairy stock should now receive some Cabbages on the pastures daily to supplement the grass, which is now getting short, unless where specially reserved for late feeding. All the cart horses and young animals of different ages, especially this year's weaned colts, should have a portion of roots with their corn and other dry fodder, Carrots being the best; but Swedes will serve a good purpose until the spring, at about the March month, when Mangolds will be best for feeding until the Rye, &c., is ready. No horses should receive more than 10 or 12 lbs. of roots per day, given in two portions, which will keep them healthy.

THE METROPOLITAN DAIRY SHOW.

THE fifth annual Show of the British Dairy Farmers' Association was opened on Tuesday last at the Agricultural Hall, Islington, and closes to-morrow (Friday). It is the largest and perhaps the best

Show yet held by the Association, the large hall being well filled. The Exhibition comprises dairy cattle and all descriptions of dairy produce, with the various implements and appliances connected with its manufacture. Goats, poultry, and Pigeons are also included, while space is also devoted to bees and honey. Prize drawings and plans for a dairy farm homestead are on view, and there is the usual miscellaneous collection of articles more or less connected with the farm or dairy.

The live stock in the dairy classes number nearly three hundred, and comprise a valuable collection of animals. Most of the classes were well filled, but the Channel Island classes especially so, and it was here where the most keen and exciting competition took place. Her Majesty the Queen sent several animals to the Show, and obtained prizes in some of the classes.

In pedigree stock for Shorthorn cows in milk or in calf there was a fair competition, the prize being awarded to "Violet," belonging to Mr. W. H. Wodehouse, Woolmers Park, Hertfordshire, an animal showing great length of frame with her milking qualities well developed, while her fine breeding is unmistakable. Her Majesty the Queen took second prize with a very fine animal, but not showing the dairy qualities of the winner. For pedigree bulls the Marquis of Exeter was awarded the prize for his "Telemachus IX.," which is a magnificent animal, and well worthy of holding the premier position if its weight, which is enormous, is overlooked.

For Shorthorns not eligible for the herd book there is a good entry, and many useful animals are exhibited. The West London Dairy Society supplied the winners for those shown in pairs with a couple of red roan cows about five years old, remarkable for their milking qualities, and no doubt obtain their position from that cause, as we should consider the second and third of superior quality. Amongst the single cows the winner was exhibited by Mr. Thomas Birdsey of Leighton, Beds; she was five years old, and shows both size and symmetry. She is a capital specimen of a dairy cow, and is very rightly placed at the head of her class, which is good throughout, having many first-class milking animals amongst them. In the Ayrshire classes there is not a large competition, Mr. George Ferme of Streatham Hill being the principal exhibitor, and takes nearly all the prizes.

The Channel Island classes we consider to be the feature of the Show. A very large entry in the Jersey classes excited the keenest competition, which gave the Judges some considerable difficulty in deciding. The well-known breeder, Mr. George Simpson of Reigate, carried off the two first prizes for cows with two especially fine animals, while Mr. Cardus of Southampton took the third prize with a cow not at all deficient in good points. Most of the animals showed both colour and breeding, and the class was a very good one. In the heifer class, in which there is the large number of forty-eight entered, Mr. Cardus was successful with a heifer not quite twenty months old, having not long calved. The only fault we could find with the winner was its being perhaps rather light behind the shoulders, but this may be remedied when it reaches the age of the other competitors, though we consider it young to have bred a calf, and question whether it is sound policy. The second prize belonging to Mr. Simpson, and the third to Mr. Le Brocq of Jersey, are both fine specimens of Jersey stock, while the whole class is especially good.

Amongst the bulls Mr. G. Simpson was again successful with a capital animal of good colour, while several animals ran him close for the prize. The Guernseys were good, Mr. J. James' cow and Mr. E. P. Fowler's heifer being really first-class animals and good illustrations of the breed. The Kerry cattle are not numerous represented, but some good animals are shown, and they are no doubt good dairy stock.

Of foreign cattle some fine animals from Holland attracted our notice as combining great size with apparently good milking qualities.

The prizes for Goats attracted an entry of 114 animals, and the various breeds are well represented.

The poultry and Pigeon Show is held in the gallery, and is very large, there being nearly two thousand entries in the numerous classes, which are exceptionally good.

The numerous classes for cheese and butter are also well filled, and all kinds of English and foreign dairy produce are represented, there being several rows of cheese, while in the centre a large pyramid of foreign cheeses attracts considerable notice.

FAMOUS POULTRY YARDS.

GARTHMYL HALL (MRS. TROUGHTON'S).

It is a pleasure to us to resume a work which circumstances have for some time interrupted—viz., the description for our poultry-fancying readers of some of the best and most successful poultry yards. Through several seasons the name of Mrs. Troughton has often appeared high in the prize lists of our great shows, specially in the classes of Dark Dorkings and White Leghorns; rumour reached us that the homes of these winners were among the prettiest and best arranged of poultry yards, and we gladly accepted a hospitable invitation to Garthmyl Hall to inspect them. We have described establishments on various scales, from the modest abodes of one breed up to those of princely magnificence where almost every variety may be found,

Each has had its own characteristic features, and so have the Garthmyl yards. They are large yet manageable, and though there is much variety in the breeds kept, they are not so numerous that interest cannot be taken in individual birds. Their origin has been the same as that of the establishments of many a lady fancier—the country was dull, and Mrs. Troughton needed occupation. This she found, and useful occupation too, in the superintendence of her poultry. Their houses and yards, well adapted to the purpose, are for the most part of her own contrivance and the work of her gardeners; the poultryman is a native of the place, who has learnt his business in them.

The chief interest of such undertakings lies much in their gradual arrangement and expansion, and the pleasure of looking round places which are the result of home ingenuity is far greater than that of walking through the most costly erections of professed carpenters. We have seldom seen a place more suited to poultry than Garthmyl; it is situated in a richly timbered valley of Montgomeryshire. We entered by a drive curving through shrubberies and woods; Deodars are prominent on each side; then on the right appears a charming pool, trees feather to its edge, and it is broken with Reeds and Sedge—a veritable Paradise for waterfowl. Further on, as we approach the house, paddocks open on the left, and we catch the first glimpse of poultry. Here and there under trees are houses, each surrounded by its yard of wattle hurdles. The inmates were chiefly cockerels. We first saw Dark Dorkings, strong and promising birds, revelling in the shade of the spreading Oaks. Likenesses run through strains of poultry as well as through human families, and it interested us to recognise in some particular points of resemblance to their ancestors in our own yards. Among them were three or four Courtes-pattes cockerels, pretty, sprightly, saucy little fellows, with the characteristics of their breed strongly developed. It has been asserted that this is but a mongrel race, which will not breed true to its points; such cannot be the case when the veritable stock is procured. Mrs. Troughton brought her stock birds from a famed French yard, and the produce seem exactly to resemble their parents. Terrible little Turks they appeared, continually chasing the big Dorking cockerels about till they sank down exhausted. Doubtless their high spirits are somewhat due to their luxurious fare, for the next morning we saw such a meal of bread, and milk, and eggs, going to them from the breakfast table as few fowls ever taste.

To the south and front of the house were these scattered poultry houses; westward through the conservatory we came on to a fine lawn, with huge trees here and there on it, and delicious views of a long valley broken with wooded knolls. Beyond in a paddock are many yards, not the cramped places often so designated, but each a grassy enclosure, with more spreading trees, large enough for many birds to live in in health; these, too, open again into the open paddock, and by turn all the birds can have full liberty. First were a quartette of yards, one house in four divisions serving for them. This is an economical plan of construction. In one were a group of Golden Poland cockerels, then White Leghorn cockerels in numbers (among them one superb bird), then Silver-laced Bantams, then Golden Poland pullets. From these yards we emerged into an immense enclosure, more like a field than a yard, all backed to the north by the shelter of a dense wood. Here were many birds, chiefly Dark Dorking pullets; and then came a troop of Ducks from a large pond abutting on this great run—such a troop of Ducks as we have seldom seen; not obese exhibition creatures, the very sight of which we abhor, and whose appropriate abodes are usually pigstyes, but the most active, hard-feathered, glossy-plumaged flock. These were white Call Ducks and sheeny black Ducks, and most numerous of all wild Ducks, the Mallards, in the fullest glow of their new plumage. We were greatly delighted with the busy quacking throng, again and again turned back to watch them, and the next morning counted no less than eighty-five at once on the water. Next on the edge of the deep wood, in a kind of bower, we visited the old Dorking hens, in warm retirement for the moult; and then there were many neat arrangements to be seen—a home-made artificial "mother," in which all Mrs. Troughton's birds are reared; most of them are hatched, too, in an incubator. One long house, too, specially took our fancy. All appliances for an exhibitor were at hand—pens for the private judging of several birds, meal tubs and corn bins and a vegetable slicer, and then on each side of a central passage larger pens for birds fresh from show, or in inclement weather, or during the moulting season. Thence we came to a particularly pretty run, a large long enclosure, protected from east winds by a high garden wall; two or three thatched sheds open into it, and some moulting birds were basking on the sunny side of fine thick Conifers. Among them, his career over, a grand old Dorking cock; in his chickenhood a

special favourite of our own, and the sire of most of Mrs. Troughton's strain.

Space fails us to recount all the contrivances we saw, but we must not forget a long row of coop-like connected sitting places, in each of which a hen can sit undisturbed, and as they are partially glazed can remain with her brood through their earlier days. From the poultry yards we passed on to a pretty sunk flower garden, and thence to kitchen gardens and vineries, where all was preparation for a neighbouring fruit and flower show; thence, too, we believe as many prizes or more came to Garthmynl as come from the poultry shows. Beyond the gardens another treat awaited us—a paddock with Alderney cows and some immensely powerful Norwegian cobs, and then the stables. Mrs. Troughton is quite as good a judge of a horse as of a Dorking, and has much longer been a fancier in this line. The cobs of Montgomeryshire have always been famed, and we saw as fine a pair in the stable of Garthmynl Hall as we have seen for many a day. But we are wandering beyond the "famous poultry yard." We revelled in the sight of it and its lovely surroundings, and hope ere long to see some of its tenants again at the Crystal Palace and elsewhere with prize cards over them. We cannot end without advising our lady readers with spare time in the country to devote themselves with like energy and ingenuity to make their poultry yards useful and famous.—C.

VARIETIES.

HULL AND EAST RIDING CATTLE AND POULTRY SHOW.—Amongst the prizes offered for competition at this Show are the Corporation Plate, value £200, for the best beast in the open classes; a piece of plate, value £100, for the best Shorthorn; a similar prize for the best Scotch or crossbred beast; and a Challenge Plate, value £100, for the best beast in the Show; entries close on November 2nd. We are requested to direct attention to the following error in the schedule:—Classes 78 and 79 are stated to be for Spangled Hamburgs. The schedule should read, "Class 78 Golden-pencilled hen or pullet, any age; class 79 Silver-pencilled, any age."

— AGRICULTURAL STATISTICS.—From the agricultural returns issued by the Board of Trade we learn that the total quantity of land returned in 1880 as under all kinds of crops, bare fallow, and grass amounted, for Great Britain, to 32,102,000 acres. For Ireland the returns show a total of 15,358,000 acres, and for the Isle of Man and Channel Islands the totals are respectively 97,000 acres and 30,000 acres. Thus for the whole of the United Kingdom the cultivated area was in 1880, 47,587,000 acres, exclusive of heath and mountain pasture land, and of woods and plantations. In Great Britain the area returned as under cultivation has increased by 126,000 acres since 1879, and the total increase in the ten years since 1870 is no less than 1,694,000 acres, or a greater area than the whole of Devonshire. Of this increase about two-thirds, or 1,187,000 acres, were in England, 220,000 acres in Wales, and 287,000 acres in Scotland. A large share of this increased acreage must be credited to the more correct returns of late years, when errors from the use of local acres, such as "Scotch" or "Laneashire" acres, and also the omission of out-of-the-way farms, have been discovered.

— ACREAGE OF CEREALS.—The area under Wheat in 1880 was 2,909,000 acres, or 19,000 acres more than in the previous year. The Wheat area of 1879 was, however, the lowest on record since the returns were first obtained in 1867, and the present year's crop was grown on nearly 591,000 acres less than in 1870. In some counties it has been stated by the collecting officers that a favourable autumn led to an increased breadth of Wheat being sown, but the large number of unlet farms, and of farms where agricultural depression prevailed, appears to have caused much Wheat land to be left in fallow, as will be noticed presently. In Barley there is a considerable decrease since 1879, when 2,667,000 acres were sown, as compared with only 2,467,000 acres in the present year. The inferior quality and the difficulty of securing the crop last year are stated by the officers in some places as having caused this decrease, but it may be noted that the present year's acreage under Barley is fully equal to the average of the last ten years. Oats were sown on 2,797,000 acres, or an increase of 5 per cent. over the area in 1879, and these figures have only once been reached since 1867; but the other stock-feeding

corn crops show a considerable falling-off, Beans being grown on 427,000 acres as compared with 530,000 acres in 1870, and Peas on 234,000 acres, against 317,000 in 1870. The imports of Maize, which compete largely with these crops, have somewhat declined during the past year, but are still more than double those of ten years ago. Taking, then, all the figures as to the corn crops in Great Britain, we find their area was 8,876,000 acres, or a decrease of rather more than 1 per cent. from the previous year, and of 7 per cent. from the year 1870.

— A SUCCESSFUL VERMONT APIARY.—A correspondent writes from Danby, Vt., to the "American Bee Journal":—"I have extracted 4000 lbs. of white honey, of good quality, from about seventy colonies. I do not know whether this is quarter, half, or a whole crop. I have spent about twenty days in getting it, and am well satisfied with the result. I sell extracted honey at 15 cents per lb., and comb honey at 20 cents. I have been in the business three summers, having started with bees in boxes; they are the Langstroth hives now, and are mostly in good working order. Have had but one swarm leave me; that went fourteen miles by observation, and how much further no man can tell. I live between two high mountains, the sun always shining into our valley at noon, and the flowers always blossoming either in the valley or on the mountain sides. Basswood, Melilot, White Clover, and Buckwheat are the main supply. I winter the bees in a building with walls 26 inches thick, and floor overhead covered with sawdust. It does not freeze in the coldest weather, or get warm during a thaw. The temperature is regulated by ventilators. The bees consume but little honey during the winter. I am well pleased with the business."

— POTATOES FOR FATTENING CATTLE.—"As the crop of Potatoes is large this year, and prices low, it is probable," says the *Irish Farmers' Gazette*, "that growers in districts remote from markets may find some difficulty in disposing of their surplus supply. We do not require to remind them of the value of Potatoes as food for pigs; but it would appear that it is not so generally known that cattle may be profitably fattened for the butcher on Potatoes. In the early part of the present century Turnips were not much known in Ireland, and a considerable proportion of the cattle fattened during winter at that time were fed upon Potatoes. Potatoes are given to cattle either raw or cooked, by steaming or by boiling. When given whole cattle will sometimes choke upon them, and Potatoes used in the natural state are also apt to cause a troublesome amount of swelling from flatulency. Both objections may be obviated by steaming the Potatoes or by pulping them and mixing them with chaffed straw or chaffed hay. If some cake, Indian meal, or crushed Barley is mixed with the mass a very fattening description of food will be obtained at a moderate cost. Potatoes lose very little of their weight by steaming, and when given to cows in milk they should always be cooked, and given while still moderately warm. In feeding cattle upon Potatoes it is advisable to begin with a small quantity daily at first, say 10 or 12 lbs., gradually increasing the quantity to 28 lbs. per day or more, according to the size of the animals, &c. With beef at 70s. per cwt. there can be no room to doubt the profitableness of using the surplus produce of this year's crop of Potatoes in fattening cattle for the spring markets."

— MORTALITY IN SHEEP.—At a recent meeting of the Devonshire Chamber of Agriculture Mr. James P. Heath read a valuable paper on this subject, from which we cite the following from the *Exeter Flying Post*:—"During the past fifteen years he had especially studied the diseases of sheep, and had practically treated over three hundred thousand with a loss of less than 3 per cent. As soon as the flock is found to be affected the owner should immediately provide the whole of the animals with shelter, and supply them with the best food—Turnips, hay, and corn—and twice a day administer gruel seasoned with salt, and with a couple of ounces of spirit mixed with it. Methylated spirit was the cheapest for stock, and at double the strength of brandy it cost only 5s. a gallon. Common fluke-rot in the earlier stages was curable; but when there was an alteration of the structure of the liver by disintegration it was useless to expect a cure. The most that could be done was to get flesh enough on them to kill, as they would not pay to keep for

store purposes. They should be given corn daily, with common table salt mixed with it, not once or twice, but continually, and powdered sulphate of iron once a week, mixed in the same manner, to supply the blood with the red globules which almost entirely disappear where death proceeds from the presence of flukes. To prevent the development of flukes when the sheep were put on low feeding land in the summer, without any other food, sow manure-salt broadcast over the pasture before allowing the sheep to graze. Two cwt. or three cwt. per acre was sufficient. If the sheep were kept for the winter on doubtful pastures, sow the salt spring and autumn as well. It was well known to be impossible to give sheep the fluke-rot in salt marshes over which the tide flows. The insect, or entozoon, might be almost described as a fresh-water fish, so nearly does it resemble a fish's shape. In conclusion, Mr. Heath said he felt convinced that if these measures were systematically carried out, there was no reason why there should be greater mortality among sheep than any other live stock, and that if they were generally adopted the youngest farmer present would never live to see a repetition of the disastrous season through which they had just passed."

QUEEN ENCASEMENT—MAKING THE MOST OF WEAK STOCKS.

WHETHER encasement of queens is of one or of two kinds is a question to which perhaps no bee-keeper is able to give a thoroughly satisfactory answer.

It is probably true that at times queens are "balled" by their own bees for the purpose of making impossible any attack by aliens which have been added or have added themselves to their number; but for myself I have of this never had any satisfactory proof. In uniting blacks to Ligurians, although I have many times had to release the queen, I have never found that the yellow-banded bees formed the enclosing mass, which should at least have happened occasionally according to the theory of defensive encasement. Yet we must remember that this theory has been advanced by some of the most observant amongst apiarians, while we all are occasionally met by such unexpected behaviour (apparently vagaries) in the workers towards the queens, that we feel as yet in the dark without a shred of explanation to offer. Our difficulties notwithstanding, it is not too bold to say that dissatisfaction is almost if not quite always the reason of the trouble. The past spring has apparently been remarkable for the unusual number of encasements occurring in hives which have been in no way disturbed. Of the embarrassments of this order which I have this year encountered, two at least seem worth recording as showing that bees will often bear with a queen that they know to be imperfect while they have no chance of getting a better, and anything which helps to explain the reasons of queen-rejection is of value as possibly leading up to some improvement in queen-introduction.

The Cyprian queen which Mr. Jackson presented to the Association I was asked to "have and to hold" for the Association and for apiculture. This queen had had the wings on the left side removed. She was introduced to a small stock without difficulty, and was quickly built up into strength. She laid magnificently, and no queen could have discharged her duties in a more queenly fashion. Royal cells were started, and frame after frame was removed in exchange for foundation to utilise the cells and keep my wingless Cyprian contented, lest in an attempt at swarming in my absence she should be lost. Yet ovipositing went on so rapidly, and queen cells were so constantly produced, that I moved her stock and put the mother into another hive on the old spot with a couple of frames of hatching brood, thinking that the bees would conclude that swarming was over, and so settle down to storing. But it was not so; queen cells continued as before to poke out their bell-like openings, whilst I began to be made anxious by noticing that the much-valued mother exhibited more and more decidedly the rickety gait which no one likes to see in a pet of the apiary. Eager to secure daughters, because I feared the loss of the mother, I continued to hatch these cells in nuclei, but I have had to pay the penalty. The queen at a later examination was found encased. It was too late, and probably would have been useless had it been earlier to try her in another hive. She is gone, and an unmated successor remains. I happily have a good number of her regal children for drone-raising in the spring (for the latter, be it remembered, will be pure even if misalliances have occurred), while another queen from a distinct portion of the island of Cyprus, and imported direct by Mr. Jackson, is going in fine order into winter quarters, and will, it is hoped, supply many brides to the drones aforesaid. My limited knowledge of Cyprians led me to

believe that the continued and exceptional production of queen cells was characteristic of the species or variety, whichever it may be determined to be; but I now believe that some defect in the mother, known to the bees alone, determined them to remove her, and that her supercession and not swarming was the occasion of the continuous production of royal cells. The encasement was only the preliminary to her ejection, and a safeguard against the destruction of the maturing nymphs. Had I been able to prevent all of these hatching within the hive no doubt the queen would still have been tolerated, in the spirit of the woman who complained of a bad husband, but added apologetically "he is much better than none at all."

It is my plan now to keep the population of my nuclei at work in nursing and raising bees by constantly giving them, as they are able to bear them, frames of eggs or larvae. In this way the nuclei instead of becoming weaker grow into strength, and are able by the time the queen comes into laying to brood all the eggs she can produce. These frames of eggs cost comparatively nothing, for in poor stocks the queen if worth keeping can always furnish more cells than the bees can cover, and by placing in the centre of such stocks an empty comb it will be furnished in a couple of days at most with a good patch of eggs. If this be allowed to remain ovipositing will be nearly suspended, the queen will become for a time comparatively idle; but by removing it and giving it to queenless stocks, the bees of the latter will be provided with employment, and in the end much strengthened, while a frame of empty comb returned to the weak stock will evoke the energies of the queen. By repeating this plan queenless bees can be kept going and at work, and queens in weak stocks can be made almost as prolific as though they were in strong stocks. This explanation was necessary to make clear the second case to which I wish to refer. A nucleus possessed a queen which had not apparently mated, although she was between a fortnight and three weeks old. In order that it might not grow weak I gave it a frame of eggs and larvae. An hour or so after that husky buzzy roar which means an encased queen attracted my attention, and looking within I found the well-known compact mass, while every bee was fanning and running hither and thither so as to make confusion worse confounded. I broke up the crowd, found her majesty, smoked them till they must have felt like the boy in "The First Whiff," and placed the queen on the alighting board, but she was seized immediately. Releasing her again I carried her about 20 yards and threw her into the air. In a few minutes she again sought an entrance, proving that she had previously flown for impregnation, but in a moment she was in the grasp of two or three and thrown to the ground. Thinking the bees knew what was best I dropped her into methylated spirit, and inserted a Cyprian cell, which has furnished a good mother now wintering at the head of a stock of unusual strength. That this case is in large part parallel with the previous one is, I think, apparent.

Bees having normally but one queen, a means of getting rid of excess seems to be a necessity of their economy, and that means is for the mature insect encasement. Ants have many queens, and they accept at once those of any nest of their own species. In each case one fact in part at least explains the other.

The only practical point that appears to come out of cases such as those I have related is this, that a queen is accepted very much more readily by a stock if the old queen has been in any way injured. Two accidental cases have occurred amongst my bees of a very startling kind proving this most conclusively, but upon these space forbids my saying anything now. May not, however, the difficulty experienced sometimes in introducing a new mother arise from some defect or injury possibly given during the time of caging? And we must admit that since bees have the power of recognising every member of their own big household, and distinguishing every stranger, it is quite likely that little matters which we cannot detect are to them as conspicuous and distinct as facial expression is to us.—F. CHESHIRE.

SUCCESSFUL BEE-KEEPING.

It is pleasant to write, read, and think of successful men and successful work. The success of the bee-keepers at Carlisle in Lanarkshire has during the last fifteen years often commanded prominent notice. One or more of these bee-keepers annually send to me statements of their results. The report this year has come from Mr. James Rennie, who, I believe, is the largest bee-keeper in the locality. He says, "This year (1880) has been a successful one, the best for profit that I have ever had in this part of the country. The bees did not gain much weight of honey from the fruit blossoms and Clover—just enough to keep them breeding. They made lots of workers. On being removed to the heather they had three days of fine weather each week for a fort-

night, and ten days at the winding-up or finish. The Heather blossoms failed before the weather. There is not a bee-keeper in Carlisle worthy of the name who had not hives 100 lbs. in weight and over, though they were comparatively light when taken to the moors. Mr. Lindsay took eight hives to the moors. He weighed them when they went and after their return. The following figures indicate how much weight was gained on the heather:—

No. 1 stock hive rose from	31 lbs. to	82 lbs.
2 "	60 "	to 143 "
3 "	45 "	to 105 "
4 "	53 "	to 140 "
5 first swarm	60 "	to 120 "
6 "	65 "	to 135 "
7 "	55 "	to 140 "
8 a turn-out	30 "	to 89 "

It will be seen that the eight hives gained 555 lbs.

"Mr. Lindsay does not take second swarms from his hives. Mr. John Jack had a stock hive that yielded two swarms, the first of which cast off two virgin swarms. The first virgin swarm broke down in going to the moors. On their return their weights were as follows:—Stock hive, 97 lbs.; first swarm, 47 lbs.; second swarm, 112 lbs.; first virgin, 37 lbs.; second virgin, 26 lbs.; total, 319 lbs.

"The produce of one of my own hives is as follows:—Stock hive, 102 lbs.; first swarm, 148 lbs.; second swarm, 76 lbs.; third swarm, 92 lbs.; virgin swarm from second, 56 lbs.; total, 474 lbs. Please to write soon and let me know if you ever knew a return equal to that of my stock hive and its swarms."

Though Mr. Rennie is a clever and successful bee-keeper, and though he realised about £40 from eight stocks in 1878, I think this is the first year he has carried the honours of the greatest success from a single hive. The late Mr. Reid, shoemaker, carried the honours one year, then Mr. Henshilwood, grocer, took the laurels of greatest success, and two years ago Mr. James Somerville, thatcher, won the honours. This year Mr. Rennie, who is regularly employed in a timber yard in attending to the engine, comes to the front with a higher figure than has ever been reached before, so far as I can recollect. The gross weight of 474 lbs. from one hive is "a pattern card" for all British bee-keepers. I commend it to the favourable notice of the bee-keepers' associations of this country, for it is well known that the hives and system of management through which such grand results and success were reached receive but little, if any, countenance and patronage from such associations, and yet the successful men of Carlisle and surrounding country are perfectly satisfied with their hives and system of management. This system has been successfully practised there for sixty years, and practised with increasing confidence.

To criticise the British Bee-keepers' Association is not my work, but I may be permitted to suggest a broader platform than is occupied at present. There are other excellencies beside the moveable-comb system, and surely it would be good policy to conserve them instead of attempting to cry them down. It has always appeared to me that the associations would exalt themselves in the estimation of the country if they encourage and hold up to view such examples of success as those now recorded. The introduction of the bar-frame hive is not the *summum bonum* in apiculture, but honey and profit. It would be pleasing indeed to see the associations turn over a new leaf and become less one-sided, less revolutionary in their aims, and broader in their sympathies and encouragements.

Some time ago three gentlemen from Yorkshire came here for an afternoon's talk about bees. One of them said, "When you die, Mr. Pettigrew, you will leave no lieutenants behind you." What nonsense! Five thousand successful men will stand by the straw hives and gain recruits and confidence all along the coming ages.

I shall be pleased if some of the Perthshire and Aberdeenshire bee-keepers send to this Journal an account of the honey harvest this year. The Scotch bee-keepers have been favoured with a finer season for honey than the English; and if the Stewarton and bar-frame hive gentlemen would send their reports we should be able to compare notes. I expect to receive more reports from Lanarkshire.—A. PETTIGREW.

HIVES AND HONEY AT THE DAIRY SHOW.

The following prizes were awarded at the Show that is now being held at the Agricultural Hall, Islington:—

BEE HIVES.—For the best *Observatory Hive*, stocked with Bees and their Queen.—1, J. A. Abbott. 2, Neighbour & Son. 3, C. N. Abbott. For the best *Moveable Comb Hive* for general use.—Price not to exceed 15s.—1, A. Blake. 2, S. J. Baldwin. 3, C. N. Abbott. For the best *Moveable Comb Hive* for Cottagers' use.—Price not to exceed 10s.—1, A. Blake. 2, C. N. Abbott. 3, S. J. Baldwin.

HONEY.—For the best display of Comb Honey in sections, exceeding 12 in number, each section not more than 3 lbs. in weight.—1, J. T. Thorne. 2, T. W. Cowan. 3, Neighbour & Son. Extra. 3, W. E. Warren. For the best 12 sections of Comb Honey, each section not more than 3 lbs. in weight.—1, T. W. Cowan. 2, A. Rusbridge. 3, J. T. Thorne. *etc.* For the best 6 sections of Comb Honey, each section of not more than 3 lbs. in weight.—1, T. W. Cowan. 2, C. N. Brooks. 3, S. Thorne.

Extra 3, J. T. Thorne. For the best exhibition of Comb Honey in one or more supers, of any material, Sectional Supers excluded.—1, A. Rusbridge. 2, T. W. Cowan. 3, Neighbour & Son. For the largest and best exhibition of Run or Extracted Honey in glass jars or bottles, each entry to consist of not less than 20 lbs.—1, A. Rusbridge. 2, R. Scott. 3, Mrs. R. Spencer. *etc.* For the best exhibition of Run or Extracted Honey in small glass jars, not to exceed 2 lbs. each, each entry to consist of not less than 10 jars.—1, R. Scott. 2, A. Rusbridge. 2, F. M. Smith.

BEE SWAX.—For the largest and best display of Pure Beeswax, in bars or cakes, from 1 to 3 lbs. each.—1, C. N. Abbott. 2, W. Hunt. 3, R. Scott.

OUR LETTER BOX.

White Dorkings (R. S.).—There are both single-combed and rose-combed. We know of no difference in their qualities, but the cocks and hens must all have the same form of comb—that is, all must be single-combed or all double-combed. They are as good layers as the Dark-coloured Dorkings.

Bee Moth Destroying a Hive (K. B.).—Mr. Cheshire, to whom we submitted the comb you sent, says, "The history of your misfortune is undoubtedly as follows:—Your skep was strong and swarmed, and then sent off a cast. After this it was necessary that the new queen should take her bridal tour, during which she was from some cause lost. The bees were now hopelessly queenless, and death quickly commenced reducing their numbers and prevented them from covering and protecting the whole of their combs. The mother Moth (*Galleria Mellonella*) gained ingress and deposited her eggs, producing the noisome brood, some members of which arrived in the box containing the debris left after their destructive work. The bees have died out, and the grubs unhindered have reduced all to a wreck." We shall shortly publish some notes on this subject from Mr. Cheshire.

METEOROLOGICAL OBSERVATIONS.

CAMDEN SQUARE, LONDON.

REMARKS.

17th.—Calm and overcast, slight fog in afternoon; clear fine evening; moonlight night.
18th.—Fine and bright throughout; moonlight night.
19th.—Rain in early morning; fair pleasant day, but overcast; rain again 9.30 P.M.
20th.—The rain which began last night turned to snow about midnight, and at 9 A.M. the ground was covered with snow nearly 2 inches in depth; snow fell until noon; fine with bright clear sky after 3 P.M.; starlight evening, lunar halo.
21st.—Very cold day, with bright sunshine.
22nd.—Wet early; overcast greater part of the day; high wind in evening; rain after 9 P.M.
23rd.—Rainy overcast morning, fine and bright after 11 A.M.; cold wind during the day.

The week is noticeable for the exceptionally early and heavy fall of snow. There is no previous instance of such a fall in October since observation commenced here in 1858.—G. J. SYMONS.

COVENT GARDEN MARKET.—OCTOBER 27.

WE have no report to make this week. Business quiet, with large consignments of American Apples on hand.

THE VINERY IN AUTUMN.

THE growth of Vines should now be completed, as any made after this time will serve no good purpose. I like to see Vines cease growing in September, the time from then until now being occupied in ripening their wood. This is the great secret of success the following season. Many Vines showed prominent marks of the imperfect ripening last year, when they were started into growth this season; but nothing of the kind should be visible next season, as the autumn has been very favourable for ripening wood. Still there may be cases where the wood is not now so ripe as it should be, and no time must be lost in aiding its maturation. Remove every lateral growth and all decaying leaves. Keep a little fire on continually, and ventilate night and day. A fortnight of this treatment will do much in ripening the wood and insuring success next year. Vines bearing fruit will be benefited by the treatment, as it will be the means of preventing the fruit from decaying, and this is no small advantage at the present time, as it is just now that Grapes are most likely to decay. The fall of the leaf and the change of the sap affects them very much. In a month or so they will be past all danger.

The remarks by Mr. Taylor in a recent issue on the damping question were interesting, and no doubt correct, but his treatment must be carried out with great care, or more harm than good will follow. I approve of and practise watering the roots even when the fruit is ripe and throughout the winter, but under chosen circumstances. Were we to water the inside border during a rainy day, and a dozen or more similar days follow in succession, I know that we should be the losers by the operation, as no matter how fire heat may be employed in a vinery during wet weather, it is most difficult to keep the fruit from decaying, and the evil is still worse when the border is wet on the surface. Vines, however, do not need water either daily or weekly at this time; and when the border requires water I advise that the supply be deferred until the first bright morning when it can be done early, opening the ventilators at the same time, and keeping the fire on all day, so that the interior of the house may be well dried by night. This is a safe plan, especially in vineries where there is not enough fire heat to render the place dry in an hour or two, or even keep the temperature up to a given point in all weathers. Where the house is moderately air-tight, and the interior dry, I think the best way is to keep the ventilators quite close in damp weather. This I have found to do much good in many cases,

and is not so expensive as firing continually when there is no occasion for it.

All Grapes should be examined daily at the present time, and for the next month. There may not be more than two bad berries to take out, but by removing them it will reduce the chances of having more, as when they are only examined once or twice a week a number will often be found together, whereas had the first one that decayed been at once removed, it is likely that another would not have been destroyed.

It is remarkable that the Black Hamburg is not more grown as a late Grape. It is a great favourite at all times owing to its excellent flavour, still it is hardly grown to meet any demand after the end of October. If I were to supply Lady Downe's, Gros Colman, and others of the kind to my employers in November and December, an explanation might soon be desired, as they, like the writer, regard quality and superiority before external appearance. Although, no doubt, Gros Colman might look better on the table than our Black Hamburgs, yet they would not bear comparison in flavour. Black Hamburgs lose their colour when they hang for a long time after being ripe, but they never lose their flavour, and one good dish of Black Hamburgs at Christmas is worth dishes of all the other late Grapes together. The Black Hamburg has much to recommend it for late use. It will keep as well as any late Grape until the month of January, and it is certainly much easier to cultivate, so as to be thoroughly ripened and coloured by September or October, than any of the late varieties. No other black Grape is so well worth growing for supply from May until January as the Black Hamburg, and I wish to impress this fact on all Grape-growers who love well-flavoured fruit.

It is surprising how fast mealy bug appears to be spreading in vineries. Many I know, who would not previously own to having such a pest on their premises, are now complaining of it. Many think it is during winter the attempt must be made to thoroughly destroy it; but this will not do it altogether. It must be searched for and killed all the year round. I have killed many more when the Vines were in leaf than when they were bare. Dressing the Vines with any mixture I have tried will not exterminate the pest, and now I prefer leaving the rods clean and killing all the insects from their first appearance after the Vines have been started into growth. In this way they may be kept from doing any harm. Fir-trec oil, so far as I have tried it, seems a greater enemy to mealy bug than any other insect, and I advise all interested in the matter to give it a trial. The Vines, glass, and woodwork may be washed with it in a very strong state.

Vines from which the Grapes were cut some time ago, and which now have the wood hard and brown and denuded of leaves, should be pruned at once. When this work is neglected until a short time before the Vines are started into growth again, it is very often imperfectly done. It does not take long to prune them, but the cleaning afterwards involves much more time; and if they are pruned and cleaned now, if it is seen in a month or two hence that they are not so clean as is desirable, they can then be attended to again before starting time.

Vines in pots are yearly becoming greater favourites. They may be grown in any kind of house. Those with no proper vinery might have plenty of Grapes by growing Vines in pots. Like many other plants, they can be bought more cheaply than

they can be propagated and grown at home. I do not mean to say many could not raise them with little expense, but they will not, as a rule, be so good as those specially prepared in a nursery, and it is by the crop which is obtained from them that we must judge their relative value. A good Vine occupies no more space than a poor one. One requires as much attention as the other, and if those of our own growing will only produce five or six little bunches to the ten or twelve large bunches to be had from the best Vines, those most to be preferred will not be difficult to decide. Many Vines in pots of last season's growth did not prove satisfactory this spring, but they will be very different next year, as everything has favoured their perfect development. Those intending to purchase Vines in pots should order them at once, and have them home as soon as possible, as I know from experience there is nothing to be gained but much to be lost by delay.—J. H. M.

HINTS UPON AND A SELECTION OF ROSES.

AT the present time many, doubtlessly, contemplate either supplementing their stock or making a first attempt to cultivate "the queen of flowers," and to whom a few hints may prove acceptable. In the first place, then, I should advise those inexperienced in the matter to give their orders at once, for nurserymen, as a rule, work on the principle that the first come be first served, and what is more with the best plants. By ordering late in the season, not only is there a risk of receiving the weakest plants, but, this season especially, there is every likelihood that all the popular varieties, and which are those that beginners and the owners of small gardens really desire, will be sold out quickly. Where but few Roses are grown they should be of the best description, and from which the greatest number of blooms shall annually be taken. In my brief list, therefore, I shall enumerate those which not only are fine summer Roses, but which also will give some really good and very acceptable blooms during the autumn months.

If a general election of varieties took place the one to head the poll, all points considered, would very probably be Gloire de Dijon. A more serviceable Rose than the "old Glory" I do not know, for whether grown as a standard or a dwarf, up pillars, on walls, or rambling over shrubs, it seldom fails to give a more or less continual supply of useful if not always well-formed blooms from the commencement of the season till severe frost commences. Pruning lightly is a mistake often committed with this and other Tea and Noisette Roses. Long ripened shoots if laid-in to their full length will flower at nearly every joint; but unless they have been much bent or depressed, the growth that should supersede these exhausted shoots will not be formed. We prune our standard Gloire de Dijon rather closely, and in addition to good heads of bloom in the summer a few strong shoots are produced each with a terminal bud, which is followed by other blooms down nearly the whole length. These are usually taken out at the next pruning. Other good Teas are Madame Falcot, Marie Van Houtte, Homère, Souvenir d'un Ami, and Safranc, all of which do well either as standards or on walls, and are really invaluable for cutting when in a bud state, giving at least three times the number of blooms that the Hybrid Perpetuals do. The standards of these are pruned similarly to the latter, weak shoots being cut hard back, say to the second or third joints; but any very strong shoots are twisted round and tied-in, as hard pruning of these only induces the formation of still stronger growth.

Maréchal Niel fails as a standard, but is well worthy of a place on a warm wall. This, or part of the tree, requires to be hard-pruned occasionally, in order to secure long and strong shoots, from which only can good blooms be obtained. For this reason I should advise the owners of apparently worn-out specimens to cut them back next February to the main stems, as, although this will entail the loss of much inferior bloom the same season, they will be well repaid for the sacrifice in the next. It is the practice of some skilful rosarians to have at least two plants of Maréchal Niel, and to cut one back each alternate year, thereby invariably securing a quantity of fine blooms. Another extremely useful Noisette, and which, unlike the foregoing, is both perpetual-flowering and well suited for growing as standards, is Céline Forestier. I find its blooms particularly good for bouquets, but unfortunately that and the beautiful Lamarque are not so hardy as one would wish. The old and vigorous Noisette Jeanne Desprez on a high wall with a north-east aspect proves exceptionally hardy, and this season has given many splendid bunches of bloom.

Of Hybrid Perpetuals La France proves by far the most floriferous,

and is one of the best. Of this and Marie Baumann, Charles Lefebvre, Capitaine Christy, Alfred Colomb, Mons. Etienne Levet, Madame la Baronne de Rothschild, Jules Margottin, Général Jacqueminot, Duchesse de Caylus, Duke of Edinburgh, and Comtesse de Chabillant we had not only a goodly number of handsome blooms in the summer, but have cut many creditable examples up to the end of September, and they are still blooming. To these may well be added John Hopper, Duke of Connaught, Beauty of Waltham, Annie Wood, Madame Victor Verdier, Mons. François Michelin, and Prince Camille de Rohan.

All the above with me are perfectly hardy. They are principally budded on the Briar stock, which suits our deep and rich soil, but they succeed equally as well on their own roots. Those who have a light and rather poor soil should order Roses that are budded on the Manetti stock, taking care when these are received to bury the part where the bud was inserted just below the surface. The Manetti stock is not recommended for the Teas and Noisettes, and if dwarf plants are required they will be found to do well on their own roots. The evil attending planting dwarfs or those on their own roots is that they are seldom properly pruned, and for this reason are soon comparatively worthless. There are two methods of pruning dwarfs, each of which answers well. My practice is to prune them precisely the same as the standards—that is to say, all spray is taken out, weakly shoots cut to about the second bud, and the vigorous shoots to the fourth, or they are left still longer in the case of the over-luxuriant growth. Some of the latter is sometimes taken clean out, and also some of the old wood is shortened in, in order to well balance the head and to keep the growth constantly starting from near the centre. The other plan is to lightly shorten all the strong shoots, and to peg these down, the bloom springing up from the entire length. Fresh growths start from the centre, which are thinned out, and the best selected to take the place of those pegged down the previous year. One year's neglect upsets the whole system. The same may be said of neglecting to prune standards, but then these being so conspicuous are not so liable to be overlooked. If dwarf, pillar, and wall-trained Roses were as regularly pruned as standards they would not so frequently be seen in a flowerless insect-infected condition, but would give equally as good displays in their respective seasons as others.

I often think that if many gardeners and amateurs knew how easily Roses are struck from cuttings we should see a great many on their own roots both in pots and in the open ground. All that is necessary is to select a few well-ripened shoots at pruning time, taking them off with a "heel"—that is to say, with a small piece of the older wood attached, and shortening back to about four or five buds. These may be either dibbled under handlights placed at the foot of a north wall, or in the open ground in the same position. A little road grit may with advantage be used, and the cuttings should be inserted firmly.—W. IGGULDEN.

PEACH BLISTER AND POTATO DISEASE.

THE discussion on "Fungi, a Cause of Disease," is of much greater consequence than at first appears, for instead of complaining that our crops are destroyed by some mysterious occurrence, we should search out the actual cause and endeavour to find a remedy. It is well known that there are certain forms of the lower orders of the vegetable kingdom that are present everywhere, and only require suitable conditions to bring them into activity; therefore if we carefully make our observations it will not be difficult to discover what is most favourable to their existence, then we should endeavour to bring about a state of things that will act against them.

It is generally acknowledged that vigorous health is antagonistic to disease, therefore I consider "S." is reasonable when he states that unripe wood is favourable to Peach blister. In that case imperfectly matured tissues form the condition congenial for the fungus, which quickly germinates, and we see the effect in the blistering of the leaves. It is, therefore, plain we should insure the ripening of the wood as much as possible, bearing in mind that excessive luxuriance or want of heat is calculated to render the tissues imperfect. Why the blister does not appear so much under glass is because the wood ripens better, the Peach being a native of a warmer climate. If our seasons are not dry and warm the wood does not ripen sufficiently to resist disease.

For the Potato disease the condition is apparently disorganised tissue. We find heavy clays, low undrained ground, thick planting, crowned with a wet season, most favourable to the disease. What is more reasonable than that we should seek the reverse of those conditions, and plant our hills and lightlands; then we should have Potatoes, not very large, but free from disease. It is desirable to select well-formed suitable-sized Potatoes for planting; the very

large and very small are not fair samples of the variety you wish to increase. The best early Potatoes are sent to Covent Garden market from Lisbon, and are grown in shallow sandy soil, and are quite free from disease. Then if light soils are so good for early varieties why not for the late also? The crops may not be so great, but a small quantity of good tubers is of more value than a large but diseased crop. It is plain we should select a warm position and light land as the best preventive of disease. We should then not have to complain of the *Peronospora* which we so frequently incautiously encourage by planting in unsuitable ground, thus producing disorganised tissues, which, combined with congenial atmospheric conditions, render the plants liable to the attacks of the fungus. Decay commences, and what we call the Potato disease is simply the result of the fungus acting upon and destroying the tissues.—R. C.

THE TUBEROSE.

ACCORDING to Loudon this beautiful flower was introduced into this country fully two centuries and a half ago, and gradually came into favour among gardeners—not so much, perhaps, from its merits as a plant and easy culture, as from the beauty of its flowers. I, however, think it is not grown by gardeners so much as it ought to be, hence my reason for calling attention to it. There is a tendency among us to cultivate plants that possess good habit and ornamental foliage combined, with but a moderate amount of merit as to the flowers they produce; but those whose ambition it is to grow the most beautiful flowers must certainly include the Tuberose. I have grown it for many years and cannot yet find a substitute for it. Even the lovely *Stephanotis* and *Gardenia*, useful as they are, have not supplanted it.

Purchase the bulbs of a respectable nurseryman, who will supply good, sound, well-ripened bulbs reasonable in price. Now is a good time to obtain them for early spring blooming. If in quantity divide them into two or three batches for succession. Pot the first at once, either three bulbs in a 32-sized pot, or one good bulb in a 48-pot. In either case use a rich loamy soil, or if the loam is poor add one-third of well-decayed manure that will pass through a quarter-inch sieve, and a little sand. Pot rather firmly, afterwards place them in a cold frame, and cover them with fine coal ashes or some other material that will run between the pots. This will keep the soil sufficiently moist for rooting to commence, which will begin in a fortnight. As they advance take them out, and for a few days place them in a position where they at first have but a moderate light, such as under the stage of a plant house. It will be seen that the young growth will gradually assume a natural colour, when the plants may have the full light and heat of an intermediate house. A stove heat is more than they need, and to have them in flower quickly a cool greenhouse is not sufficient. After making a little foliage the flower spikes begin to appear, and as they grow to from 2 to 4 feet in height and are very slender, a stake must be placed to each. Each spike if good will produce two dozen blooms in succession, pure white with a most delicious fragrance.

There are three or four so-called good varieties in cultivation, but the best are the old *Polianthes tuberosa* and *P. tuberosa fl.-pleno*. When in bloom they are conspicuous if placed in the conservatory with the spike of flowers arising just above other plants, but they would be principally required for cutting. The perfume is strong, therefore for room or any part of house decoration too many must not be employed at one time. During growth the plants are subject to the attacks of green and black aphides, which infest the spikes of flowers. Liquid manure given twice a week will be found to benefit the plants, and by potting in succession they may be had in flower during the greatest part of the year. Some cultivators assert that if after flowering the bulbs are well ripened off they will flower as well another year; but although I have tried that plan I could not find that they were to be depended on, as not above one-third of the bulbs flowered, and the spikes were short and the flowers small. No doubt most florists and growers for market around large towns find a ready sale for the Tuberose flowers. They are among the most useful for cutting for bouquets, wreaths, and buttonholes, as they are sweet-scented, pretty, and last a long time.—THOMAS RECORD, *Sheffield*.

TRANSPLANTING FRUIT TREES.—In the last issue of the *Journal* I read some instructions regarding transplanting. Let me say for the encouragement of any who may have such work before them this winter, that I lifted a row of what had been dwarf standard Apple trees, but which have now become large. The soil being very stiff I had a large tub with water at hand into which every tree root was laid and well washed, all bad root

or canker was removed, and the trees were then planted as described by your correspondent. The result has been that we had a crop of Apples last season, whereas these trees had previously seemed to be decaying.—A. B.

FUNGI A CAUSE OF DISEASE.

I VENTURE to say a few words with regard to the discussion in the *Journal of Horticulture* between Mr. Luckhurst and "S." about the Potato disease, cause, and effect, and whether fungi are the results of disease or the cause. It seems to me that there is a third point not touched upon. The cause of a disease is not the same as the disease itself, and the result or effects produced by a disease is, again, different from the cause of the disease, or the actual disease itself. Take, for instance, disease in animal or human life. Infection is the cause of disease, as in the case of cattle plague or pleuro-pneumonia. The result of the disease differs according to the treatment, or the power of resisting it, or the malignity of it. Some diseases are far more infectious than others; certain states of vitiated atmosphere and climate induce disease in many cases; but we must distinctly draw a difference between the cause or origin of disease, the disease itself, and the results. I need not enter upon so wide or difficult a subject as the infectious natures of disorders, such as typhoid and scarlet fevers, small pox, &c., but it is an undoubted fact that the most dangerous diseases are often the most insidious, and arise from apparently small causes.

The question in discussion between Mr. Luckhurst and "S." is whether fungi are a cause or only a result of disease. I presume Mr. Luckhurst would wish us to infer that it is owing to a previous disease or injury to the plant that fungi are produced—in other words, that the plant is diseased, and owing to the disease the fungi grow. Why, however, in the case of the Potato disease was it unknown in England previous to a particular year, 1845? and why is that disease, which was then introduced into England, always accompanied by the attack of the *Peronospora infestans*? Our leading fungologists, who have carefully examined the question, have certainly decided that the injury to the Potato plant is caused by the spread of the fungus by means of spores and mycelium through the tissues of the plant, the leaf, haulm, and tubers; that as "A LINCOLNSHIRE POTATO GROWER," in the *Journal of Horticulture* of the 23rd September, in calling attention to an article of Mr. Worthington Smith's in the *Agricultural Gazette*, points out that the spores of the *Peronospora* are present everywhere, and that the resting spores have great vitality. Only those who have carefully studied the question have any idea of the number or the minuteness of the spores of the various fungi, and this which attacks the Potato seems to be a remarkable example of it. There are certain stages of growth combined with atmospheric influences, such as moisture, warmth, &c., which predispose the plants for the reception and growth of the fungi. We may thus say with Mr. Luckhurst there are causes which help the disease; but surely these causes are not the disease itself, but the injury to the plant and the destruction of the crop is caused by the growth of the fungus. The fungus cannot in my opinion be called the result of the disease, but is the actual means by which the Potato plant is destroyed and the tubers made unfit for use, and therefore may be considered as the disease itself. There are kinds of Potatoes no doubt less liable to the disease than others, but experience has proved that none are altogether capable of resisting it; and though in the Scotch Champion, Magnum Bonum, and others of that character which have harder and more fibrous haulms, the tissues seem less favourable for the growth of the fungus, still no Potato is disease-proof, and we cannot, I think, under these conditions separate the fungus from the disease itself, or say that the fungus merely grows on plants previously diseased, which seems to be the line of argument Mr. Luckhurst takes. The same seems to be the case in Peach-leaf blister. Cold winds are the predisposing cause, but the disease itself is from the growth of fungus, which finds the leaf injured by the cold winds a suitable nidus; the result is the destruction of the leaf by the fungus, and the disease often spreads to other leaves on the same tree which were not previously injured by the cold winds.

I had written the above remarks previous to reading the *Journal* of the 21st, which contains another letter from "S." on the subject. I think what he there says should be sufficient to show Mr. Luckhurst that his statements with regard to fungus being always or even generally the result of disease will not hold true in the generality of cases. In the *Journal of Horticulture* 14th Mr. Luckhurst tried to explain his original statement, where he uses the expression "In every instance the idea is erroneous," by saying his statement was only "general" as far as it referred to the three forms of disease mentioned. Certainly the words "in

every instance" could not without this explanation be supposed to refer only to the three in question; but even if he intended his remarks only to be so applied, it seems very bold and decided to affirm that the generally received opinion with regard to the Potato disease and Peach blister is altogether erroneous. I have certainly seen the foliage of the Potato plants injured by the mycelium, and the spots so produced, long before the legitimate functions of the foliage had been fulfilled. There can be very little doubt in the minds of most persons who have taken notice of the spread of the disease, that under certain favourable atmospheric conditions and on wet or cold soils the disease will progress most rapidly, especially when the plants are too close together or growing in confined spaces, and that the proper functions of the leaves and haulms are arrested before the tubers have completed their growth. Mr. Luckhurst's remarks about the Dr. Hogg Peach not suffering again from the blister after it was covered with glass does not in the least prove in my mind that the disease itself is not caused by a fungus, or rather that the blister is ever found without the fungus. There can be little doubt the cold spring winds predispose the leaves to this disease, but are not the actual cause of the disease.

While on the subject of Potatoes and Potato disease, I venture to say that many Potatoes vary so much from the nature of the soil in which they are grown and the treatment received, that the sorts which succeed in one place do not come to perfection in another, or are much deteriorated. I have at one time or another tried a great many varieties, and have found that many which succeed in good soil and favourable seasons are inferior in others. Unfortunately some of the best varieties, as the Ashtop Pluke, Lapstone, Snowflake, Myatt's Prolific, and others, are more liable to disease. The Scotch Champion have proved very good with me in light soil, but they require plenty of room so as to have air and light; the same may be said of the Magnum Bonum and Red-skinned Flourball. It is a pity that in judging Potatoes more attention is not paid to quality rather than quantity, as in many instances I have seen the premier prizes carried off by Potatoes not fit for a gentleman's table, and this, if I may judge from the accounts given, was much the case at the last large Exhibition at the Crystal Palace.—C. P. P.

No one can fairly object to positive statements provided they are supported by a reasonable show of facts, but when a generally accepted opinion founded on undeniable evidence is assailed something more than mere positiveness is requisite. Every man is entitled to enjoy his opinion, but before making it public he should at least be at the trouble of obtaining proofs of sufficient weight to render it worthy of consideration. This I maintain Mr. Luckhurst has not done, for I fail to perceive in the whole of his communications one fact that is not conformable to the fungoid origin of the Potato disease and Peach blister. I, too, write "for gardeners and gardening," and it was a desire that doubtful statements should not go unanswered which first prompted me to enter on this discussion. Mr. Luckhurst must be aware that he occupies a high position among horticultural writers, and consequently an opinion from him would possess much more weight than from anyone of less acknowledged ability as a practical man. It is for this reason that he should be careful in what he writes to avoid propagating errors which are always likely to be accepted when supported by authority.

In his last communication he has gone wide of the subject, whether from inadvertence or a desire to obtain a champion for his cause I know not, but in either case it is plain that he ineffectually endeavours to draw support from "NORTHERN GARDENER'S" remarks upon lifting Potatoes, which had no reference to the cause of the disease. Why does Mr. Luckhurst still continue to ignore the questions I put to him? I have met all his statements and questions fairly and openly, why does he not act similarly? However, even at the risk of repeating myself, I submit the following facts to his consideration, and I challenge him to prove them incorrect before he can reasonably assume to have established his opinion. The fungus *Peronospora infestans* produces by its action on the substance of the stem, leaves, and tubers of the Potato that condition which we term Potato disease. The same disease first appeared in this country attended by the fungus; neither had been previously known here, and the disease is never found without the fungus. Peach blister is similarly attended by the fungus *Ascomyces deformans*, which is known to possess the power of injuring the tissues of the leaves, producing the appearances that characterise the disease; whereas cold wind, though acting injuriously upon tender foliage, does not produce a similar condition, but causes shrivelling or a brown scorch-like appearance.

As to the conditions that favour the growth of these two fungi,

the following facts are generally accepted and are in accordance with my experience. First, regarding the Potato disease, it has been proved that a particular temperature and moisture are requisite; and further, if the former be sufficiently high, the greater the abundance of moisture the more prevalent and disastrous the disease proves, consequently anything that tends to promote the accumulation of water in the soil or atmosphere has an equal tendency to encourage the growth of the fungus. When moisture is so abundant the plant becomes charged with water, either rapid growth ensues, thus forming loose tissue that the mycelium of the fungus can readily penetrate, or the flow of the sap becomes temporarily checked, as, if the moisture is not disposed of by evaporation or growth, absorption is diminished, and there is an approach to stagnation that may also be a condition suitable to the fungus which then commences the destruction of the tissues. We can on these views understand why in very light, well-drained, or sandy soils there is little disease, that wide planting is beneficial, and that those varieties with erect firm woody stems and abundant foliage are better enabled to resist the attacks of the fungus, because they can dispose of a great quantity of moisture either in growth or by evaporation from their more extensive foliage surface.

"INTERLOPER'S" statement that cells are burst by the absorption of abundant moisture is utterly indefensible. Cells are connected with each other, and it is through the walls that the sap passes in rising to the leaves. The growth or degree of evaporation from the foliage determines the rapidity of the absorption. When the former diminish the latter decreases also; so that as the amount of moisture in the cells is determined by the general requirements of the whole plant, the quantity will be greatest when the demand is greatest, provided there be sufficient moisture in the soil; but as then the sap is rapidly passed on to supply other parts of the plant it has no tendency to cause bursting; consequently, according to "INTERLOPER," the cells must be burst by an amount of moisture which is less than the greatest they can contain—an obvious impossibility. I may remark that most of "INTERLOPER'S" other statements as to the conditions under which Potato disease appears are very reasonable.

I have previously stated that I regard unripened wood as one of the chief conditions that favour the production of Peach blister, and from further observation and reflection I am confirmed in that opinion, but the subject requires investigation. Mr. Luckhurst might have seen from my remarks on this point at page 368 that I considered Peach trees under glass are less liable to blister owing to the wood being better matured.—S.

LAPAGERIAS AND OTHER PLANTS AT SOUTHGATE.

"WHY do they call you Lapageria Tom?" was the question put to Mr. Howard, the very successful owner of the largest Lapageria manufactory in the world. "I don't know, except that my name is William," was the quaint reply; and having heard so much of him and his work I very cordially accepted the offer of my excellent friend Mr. Horace Mayor of Winham Hill, when staying with him, to drive me over to his establishment. Now I had seen Lapagerias, as I have stated, at Messrs. Fisher, Son, & Sibray's at Handsworth. I had wondered at the numbers of plants, at the rapid manner in which they were propagated, and the successful manner in which they were grown; but having seen both places I am at a loss what to say. The method of propagating is the same—viz., that of growing them in beds and layering the shoots, from the axils of which a plant starts forth, so that multiplication proceeds very rapidly. But there is one difference in the method of culture—they are grown in a much cooler temperature at Southgate than at Handsworth. Indeed they are treated almost as if hardy, certainly not regarded as tender as a Geranium, and I saw a whole frameful of plants which had never had any fire heat. Houses are specially devoted to them, where they are trained up to the roof much in the manner in which pot Vines are found in May, and in this way they bloom most profusely—ropes of bloom with twenty or thirty blossoms on them; and on turning out one of the pots to show me how they rooted I was astonished to see the mass of strong fleshy roots that they contained, in fact ready for a pot twice the size. The object, indeed, of Mr. Howard seems to have been to get as much health and vigour into the roots as possible, and this he has attained with a corresponding strength of growth. It seems that one has to be very particular in touching the young shoots, for they almost invariably die away when that is carelessly done. Such success has been obtained both at Sheffield and here in the propagation of Lapagerias must soon bring this very beautiful plant within the reach of everybody who has a greenhouse.

Another speciality of Mr. Howard's is the very beautiful Chrys-

anthemum frutescens Etoile d'Or, which he introduced from abroad, and of which he has now somewhere about ten thousand plants; but even this is not enough, and he had telegraphed that very morning for a thousand more. These are grown more for the sake of their blooms than for the plants themselves, and by judicious management they may well nigh always be had in bloom; and for the bouquet makers they are at all times most valuable, while as pot plants able to stand the heat of a sitting-room they are also most desirable. A large houseful of *Adiantum euneatum* for cutting shows how valuable this pretty Fern is. All the accessions that have been made to the class do not displace it, *A. gracillimum* and *A. farleyense* are not nearly so much appreciated.

Another plant to which Mr. Howard has devoted considerable attention is the perpetual-flowering Carnation. He has endeavoured to procure some which will not deserve the name of Tree Carnations, but by the dwarfness of their habit be more readily accessible. It is not every greenhouse that can house these tall plants, but most amateurs would welcome some not so tall, and this Mr. Howard has succeeded in obtaining. Houses were filled with nice stubby plants which grow about 18 inches high, and these he is preparing to send out in six different colours. These come in very usefully for cut flowers.

The place itself does not impress you much as you enter it. It is in a gravel pit, and no end of troubles have been occasioned by the water; but rough though it seems, you very soon find out that it is in the hands of a man who knows what he is about, and whose skill and industry will surmount any difficulties he has to contend with.—D., Deal.

THE CHAMPION POTATO IN THE NORTH OF SCOTLAND.

It is surprising how the cultivation of the Champion Potato has spread over the Highlands of Scotland. It is in general favour both with farmers and cottagers, the latter also esteeming a variety they call Red Rocks.

I planted for the first time in the garden here one peck of Magnum Bonum, from which I obtained three bushels of tubers of excellent quality, not so waxy as one of your correspondents describes them. I hear that at the Inverness Farmers' Grain and Root Show Magnum Bonum was first and Champion second in the late Potatoes. I hope to see in two or three years that the Magnum Bonum is as generally known in the Highlands of Scotland as the Champion is, both of which are the best disease-resisting Potatoes we have.—ANGUS McDONALD.

ABNORMAL GROWTH IN THE GRAPE VINE.

REFERRING to Messrs. Taylor and Iggulden's notes on this subject, may I be allowed to say that the Vine alluded to here as having been rooted at the upper end and then severed from the original roots was so treated by way of experiment, and that the idea was perfectly original, as was also the thought of rooting the Vines at all in that way? but I did not, nor do I consider such an idea more than a natural one for any man of ordinary intellect. Had I thought otherwise my pride would have received a severe shock on a friend referring me to page 810 of the *Gardeners' Chronicle* for 1875. There I found recorded that Mr. Rochford, Page Green, Tottenham—a successful market cultivator—had been practically testing for years what I considered my own discovery. To say that I was not at first a little disappointed would be contrary to human nature; but, on the other hand, to counterbalance my disappointment I had the opinion of a practical man that my intended discovery was already a success, and so I went on with it in greater confidence. Now I am more enamoured of it than ever, and that for a very good reason—viz., that the Vines evidently appreciate being rooted at each end, as is shown by the production of finer Grapes.

The house in which the experiment has been carried out was originally a lean-to, but the Vines did so well that the back wall was taken down and the house made into a span, the Vines being trained down the roof, and as soon as they reached the bottom a border was made and the tops pegged into it. The house is 51 feet long and 25 feet in width; the length of rafters, both sides, being 36 feet. There are ten Vines in the house, each Vine having two rods, so that each Vine has from border line to border line upwards of 40 feet run of rods, and each Vine three distinct sets of roots, caused by the rooting of each rod at the ends. The one Vine that was severed after the first season's rooting was merely tried to test its fruiting powers when turned upside down. The portion left was 6 feet long, and the same season carried and finished off perfectly four good bunches of fruit, certainly as good

as those on the parent Vine. Perhaps I ought to add that the tops, or rather what were the tops, the first season persistently pushed young shoots through the soil, which were as persistently rubbed off, and now they manifest no disposition to throw up suckers or shoots, and the Vines are of equal strength throughout.

I am not a scientific man, so cannot solve the problem as to the changed route and circulation of the sap, hence I must leave that to the vegetable physiologist. It is sufficient for me that the experiment has been successful as regards the production of fine Grapes.—W. WILDSMITH, *Heckfield*.

THREE GOOD ORCHIDS.

ODONTOGLOSSUM ROEZLII.—Though this species may not be so useful as *O. cirrhosum* or *O. Alexandræ* it is nevertheless one of the finest of the genus, and from the easiness with which it is cultivated it is one of those sorts which every gardener may safely take in hand. I have not tried it in a lower temperature than 55° throughout the winter; perhaps 5° higher would be better, as it is constantly growing. Our plants are grown about 9 inches from the glass. It does not root deeply, but produces numberless rootlets through the surface of the potting material. It is very necessary to keep the soil always in a fresh condition. When repotting I wash the old material from the roots and place the plant in pots just large enough to hold the roots, pressing the soil in rather firmly. The compost used is the fibres of peat, living sphagnum, and small pieces of charcoal in about equal proportions; in this I find it roots freely and requires a good supply of water when in full growth. At no period of the year should water be entirely withheld.

EPIDENDRUM VITELLINUM.—This very distinct Orchid is another species which ought to be found in every garden. I have heard it called difficult to manage, but cannot say that I have found that correct. I commenced with a stock of newly imported plants, which arrived in the early part of the year, and would advise those who intend to add this species to their collection to obtain their plants the same way. They can be bought at a much cheaper rate than established plants, and are very easy to establish; the second season's growth in many of the plants giving larger bulbs than those made in their native country. When received, after washing them, nearly fill as many pots as will be required with clean potsherds, on these place some sphagnum and a small portion of a soil composed of peat and sphagnum, rather more of the former than the latter, adding a few small pieces of charcoal or potsherds, then place the old roots so that the plant may be kept firmly in its place after the rest of the compost has been added. The base of the old pseudo-bulbs may be slightly buried, which will cause them to break freely; keep them well above the rim of the pots, and water only when the soil requires it; place the plants where they can at all times have a supply of fresh air, and when they are close to the glass I find them do very well in the same temperature as cool Orchids, only they will not bear a stagnant atmosphere. After the young growths have made some progress the second year turn out the whole stock and repot them if necessary, removing the whole of the old soil; do not drain the pots so much this time, and give the roots a greater depth of soil, supplying water when it is really required. Under such treatment I have found this Orchid succeed very well.

CYPRIPEDIUM INSIGNE.—This is another easily cultivated Orchid, and one that well repays good treatment. Our plants are repotted every second year; if they are allowed to remain longer without repotting, the flowers are much smaller than they ought to be. I treat these like ordinary plants in the mode of potting. For plants in 6 or 7-inch pots about 1½-inch depth of drainage is given; the roots of the plants are washed clear of all old material, and the new potting soil is packed equally amongst the roots in repotting, leaving half an inch underneath the rim of the pot clear for receiving water. The compost I employ consists of peat, sphagnum, dry cow dung, and broken potsherds, and the second year a surfacing of cow dung is given the plants, and soot water used for watering. About twice a week is as often as they require water. After flowering our stock is placed in a cold vinery, and in spring the plants are kept warmer. Through summer a pit is found for them, and when in flower they may be placed wherever they may be required.—R. P. BROTHERSTON.

WINTERING FUCHSIAS OUTSIDE.—If there are any who have Fuchsias outside at present, or who have not space sufficient to secure all under cover, I would recommend them to make a trial of bedding-out their plants in the mixed border. I take them out of their pots, prepare and manure the spaces intended for them,

and make the soil as loose and as friable as possible. This is the only care or trouble necessary, except to cover or mulch round the roots with cocoa-nut fibre, coal ashes, or fine cinders; or what I consider better is dry peat soil made into a conical little mound. The centre of this remains dry a long time thus built, and while dry no frost will penetrate it. If any of those substances cannot be readily procured fine hay, bracken, &c., may serve as the best substitute. Compare this with the ordinary custom of wintering under the stages, where space can often be but badly spared; where the plants are often, too, if in a cold house, as badly frozen almost as outside; where drip from the roof or from the watering destroys the majority of the best plants; or what is even worse, where the heat is maintained and the plants are prematurely forced into leaf and flower. The flowers produced by plants established in the open ground have been much superior to those produced by plants in pots.—W. J. M., *Clonmel*.

LAWN MOWERS.

MESSRS. JAMES CARTER & Co. do not seem quite satisfied that I did not, in my few remarks on this subject on page 374, give more striking proof of the advantage of leaving the grass uncollected. Our use of the box is limited to one round of the machine next the flower beds and by the side of walks; and if Messrs. Carter & Co. have ever used a mowing machine at the rate of four miles an hour they would observe that the machine does not deposit the grass on the exact spot it was cut from, nor in the exact wake of the machine; so that I may say that our grass is virtually all mown without the box as far as the distribution of the grass is concerned.

My idea of a well-kept lawn is that it should never appear to need mowing. It should always be done before it needs it; and if I were to see a man mowing without a box where the grass is so rank that he has to sweep it up afterwards I should not have a high opinion of that man's intelligence.

I advocate having the grass uncollected on the score of economy as well as for the benefit of the lawn. With a 20-inch machine it takes us five hours each time to mow without the box, but if we use the box it takes us an hour and a half or two hours more; so that it amounts to this, that we can very nearly mow three times without the box during the time we would be doing the work twice with it. The grass is thus always in order instead of being out of order two days a week; the work is much easier, and there is no necessity for applying lawn manure in the spring.—R. INGLIS.

STILL MORE ABOUT POTATOES.

ALTHOUGH I am not at present engaged in Potato cultivation I shall not say anything in these notes that has not been gathered from the most authentic sources in this district—the fertile tract of land near the seacoast, and stretching from the Tyne to the Wear, anciently known as Werewickshire. The soil here is admirably adapted for Potato-growing; overlying as it does the magnesian limestone, it seldom becomes waterlogged where any attempt at drainage has been made. The great breadths of Potatoes in this neighbourhood are all grown by farmers, market gardeners do not grow them extensively. Last year Champion was the only variety that paid well and that withstood the attacks of the disease. This year, as might have been expected, Champions were largely planted; what the results will be yet remains to be seen. Champions in this district are supposed not to be fit to lift till the latter end of October. Regents and Victorias are perhaps next in demand here, nearly everybody having his own strain of each variety. One of my immediate neighbours sold a breadth of Dalmahys in the latter part of August, and they were lifted in the early days of September. The tubers were very slightly touched with disease, although the plague had been plainly visible in the haulm for several weeks. The dealer who bought them informed the writer that the yield was 8 tons an acre, which is considered a heavy crop here. If people would give the absolute yield of Potatoes, instead of "at the rate of," it would be more satisfactory—of course I am alluding to large growers; a small grower can only give relative values. The price, I had almost omitted to say, was £19 per acre, the grower ploughing the crop out, and the purchaser doing the rest of the work, such as sorting, weighing, carting, &c.

The same farmer has a breadth of Champions, for which he wants the same price per acre, but for which his highest offer is only £15. The writer had the pleasure of going over the field with the grower and trying the Potatoes, which certainly did not appear to be either such a heavy crop, such large tubers, or such good quality as the Dalmahys, but they were almost free from

disease both in haulm and tuber. The disparity of the price received for one crop and that offered for the other fully bears out Mr. Beachey's assertion that other varieties sell for more than Champions, but I cannot admit that they sell for £5 or £6 per ton. One farmer here is selling his crop by weight at the low price of £2 10s. per ton; another is receiving £3, both for Regents. On the farm above mentioned, where the Dalmahys were grown, Magnum Bonum has been tried as an experiment. The number of tubers per root is very great, but they are not large enough for market purposes, and are not, at least now, of good quality, but are free from disease. They will be tried again next year at 4 feet apart, this year they were rather crowded. A neighbouring grower, who this year planted largely, is lifting to-day (19th October) his Regents. I am afraid they can scarcely be called a crop, as all told they will not weigh 5 tons an acre, and quite one-half of them are diseased. They are being disposed of at £3 per ton.

Mr. Beachey says that "disease is (practically) nil" in Devonshire. In Werewickshire it appeared with the sultry humid weather in the latter part of August; the days were still and quiet, not extraordinarily hot, and the nights were warm and foggy. Disease under these conditions made rapid progress in the haulm, but did not affect the tubers till the deluge of September seemed literally to wash it down to the roots. After the second week in September the fall of rain was discontinued, in fact has been ever since with the exception of light showers now and again, and we had bright, warm, breezy weather, which partially checked the disease. It would be difficult to over-estimate the value of a breeze of wind moving the haulm of a crop of Potatoes all the season. I have not been able to discover much progress that the disease makes under such conditions, its most rapid strides are made in still weather. The farmers may, perhaps, be blamed for not lifting their Potatoes at the first sign of an attack of the enemy, but farmers are like other folk—they know their own affairs best, and the changeable weather came upon us just in the middle of the harvest, and no doubt they did everything to the best of their judgment to secure first their corn, which was no easy matter, and then the rest of their crops.—PETER FERGUSON, *Mere Knolls, Monk Wearmouth*.

ANEMONES.—No. 1.

THIS is a somewhat extensive genus, mostly confined to the temperate regions of the globe, some species being found at considerable elevations. The popular name, Windflower, is derived from the old superstition that they only opened their flowers when the wind blew; but as they are found in exposed situations it would be difficult to find open flowers when the wind does not blow, especially as the majority bloom during the early spring months. They may be briefly described as dwarf-growing plants with tuberous roots, which in some species are little more than thickened rootstalks, but in others become spread out into large, irregular, flattened masses. The leaves are twice cleft; the scape erect, simple, or branching; involucre composed of three leaves. When the stem is unbranched the flowers are all within a common involucre, but when it is branched each flower is furnished with one. In the case of single flowers the petals are entirely wanting; the absence, however, is well substituted by the large highly coloured sepals. Under cultivation Anemones readily become double-flowered when the petals are numerous, being developed at the expense of the stamens. The genus has been divided into three groups or subdivisions—viz., 1, *Anemone*; 2, *Hepatica*; and 3, *Pulsatilla*. *Anemone stellata*, the Star Anemone, and *A. coronaria*, the Poppy Anemone, are largely cultivated as florists' flowers both in the single and double state, the last named especially having received great attention at the hands of the French and Dutch growers. They are all plants of easy culture, thriving best in a rich light loam, but seldom fail in any ordinary garden soil. They may be increased by divisions of the root or by seeds.

A. alba.—A rare species at present in English gardens. It is a dwarf plant, seldom exceeding 6 inches in height, with divided leaves, flowers large and pure white. It flowers in June, and is well represented in the accompanying engraving. Native of Siberia.

A. alpina.—This is a bold-growing species in a cultivated state, and one of the most plentiful plants in its native habitats, being distributed from the base almost to the summit of the mountain ranges of Europe. It is found to vary from a few inches to about 1½ foot in height, the latter being its usual proportions under cultivation; hence it forms a beautiful clump in the border, where I prefer it to the rockery. Leaves with deeply cut segments; flowers large, white inside, tinged with light blue

on the exterior; sepals slightly spreading. Flowering from April to May. Alps of Central Europe.

A. alpina, var. *sulphurea*.—A plant exactly resembling the type, but with pale yellow flowers, forming a pleasing contrast. It flowers at the same time as the last.

A. angulosa.—This fine species belongs to the group *Hepatica*, and it resembles in many respects the well-known *Hepatica triloba*

Fig. 76.—*Anemone alba*.

of our gardens, from which, however, it may be readily distinguished by the size of its flowers and by the large palmate leaves, which are five-lobed and deeply toothed, the flowers $1\frac{1}{2}$ inch in diameter, with deep sky-blue sepals. It forms a lovely border plant, attaining a height of 9 to 12 inches, and blooms during the spring months. Hungary.

A. apennina.—A lovely plant, by some considered an indigenous species; but although naturalised in a few localities it cannot be claimed as British. It attains a height of about 6 inches, and soon forms beautiful clumps of vivid green spangled with brilliant azure blue flowers. March and April. Italian Alps.

A. baldensis.—This is both a rare and beautiful plant. It should be planted in a sunny open spot in the rockery. Leaves deeply divided into linear lobes. Flowers large and spreading, pure snow white, the exterior suffused with rosy pink. April and May. Austrian Alps about Kaernten.

A. blanda.—This beautiful plant slightly resembles *A. apennina*. The leaves, however, are scarcely so high, thicker in texture, and deeper green. Flowers large, deep sky blue. January and February. Greece.

A. coronaria.—Of this species there are now an immense number of varieties both double and single, and of nearly all shades of colour from brilliant scarlet, crimson, purple, blue, and rose, also flaked and striped flowers in all shades. The single flowers are Poppy-like, whilst the doubles have the sepals formed into an outer guard like those of a double Hollyhock. These varieties are very effective both as border plants and also as spring bedders in the geometrical garden. The roots should be planted during the months of October and November, and should the weather be very severe a slight protection will be of great advantage. This planting will produce a brilliant display in early spring, and if a succession of these flowers is required another planting in the

beginning of March will keep up a fine display until the month of June. When the leaves have entirely decayed and the roots ripened they must be taken up with a fork and placed in a shady place until thoroughly dried, and then stored away in some cool airy place which is not subject to any great variation in temperature, where they may remain until again required for planting. The typical form, which is shown in fig. 77, has twice-cut deep green leaves; flowers Poppy-like and large, variously coloured—usually scarlet or some shade of purple and blue—with a distinct ring of a different colour near the base. Native of the regions about the Mediterranean.

A. dichotoma.—Although less showy than some species this is a very desirable plant, of a robust hardy constitution, about 9 to 12 inches high, forming pretty clumps either in the border or on the rockwork. Leaves dark green; flowers upwards of an inch in diameter, white. May. Siberia and Canada.

A. Hepatica.—This plant and its varieties, perhaps better known by the name of *Hepatica triloba*, used to be more largely grown than at present; but I have much satisfaction in finding the public taste coming round again to so many of these useful old-fashioned flowers. The plant grows 4 to 6 inches high. Leaves heart-shaped, smooth, entire, deep green. Flowers freely produced above the leaves. I cannot recommend a more beautiful plant than this one, with its varieties, all of which should be grown either as border plants or on some little upland spot in the rock garden. They delight in a compost of rich strong loam, and do not like to be much disturbed. The following are the principal varieties, amongst which I cannot include the *alba plena*, for although much has been said and written respecting this form I have never found it in any garden:—*A. Hepatica*, pink; *caerulea*, blue; *caerulea fl.-pl.*, double, rich indigo blue; *alba*, white with pink anthers; *nivea*, pure white; *Barlowii*, purplish mauve;

Fig. 77.—*Anemone coronaria*.

rubra, red; *rubra fl.-pl.*, double red; *splendens*, crimson; *lilacina*, pale blue. March and April. Europe and North America.

A. japonica.—No more beautiful border plant for autumn flowering can be grown than the one now under consideration. It accommodates itself to almost any soil, and yields a maximum of pleasure without even the slightest care. It grows from 2 to 3 feet high in good soil. The flowers are large, bright rose colour, with sepals so numerous as to form a semi-double flower. It blooms from July until late in the autumn. Japan.

A. japonica alba.—This variety has somewhat less divided leaves than the type, otherwise its habit of growth and height are

similar. The flowers, however are rather larger and snow white ; stamens golden yellow. It cannot be too highly recommended. July until late in the autumn. Japan.

A. nemorosa.—The beautiful Wood Anemone of our own island, who does not look upon its charming flowers with delight during the early spring days, and hail it as a harbinger of brighter days to come? Its beauties, however, are not confined to our own land, for it is widely distributed throughout Europe. It grows from 6 to 9 inches high, and is a charming plant either for border, rockery, or wild garden, being equally at home in all. The flowers are solitary, on long footstalks, white, sometimes tinged with reddish purple on the outside. In addition to the ordinary form there are now two beautiful double-flowered varieties, which are charming companions to our woodland beauty—viz., *A. nemorosa alba fl.-pl.*, flowers large, very double and pure white, and *A. nemorosa rosea fl.-pl.*, a double rosy-red form, extremely handsome. March and April. Europe (Britain).—H.

PLANTING POTATOES IN THE AUTUMN.

NOT only in the Journal but in the *Times* have letters recently appeared in praise of this obsolete plan. After giving it a fair trial by planting two or three acres in the autumn for a few years—I cannot be more exact than this—my father was obliged to revert to spring planting again because of the lateness of the autumn-planted tubers, the weakly growth from seed partly consumed by slugs, and numerous vacancies where the seed was eaten. This was about thirty years ago, and I have never seen it practised since then. The land was a deep heavy loam. A heavy dressing of half-decayed manure was dug in, and the planting was done by inserting a spade quite 6 inches deep, lifting the soil slightly, and putting the Potato down behind the spade into the manure, which thus served to protect it from frost.

Any notice of the letters bearing upon this subject would have been unnecessary but for the attempt of some writers to claim merit for it upon the score of its affording a heavier crop and immunity from disease. No wonder there is so much uncertainty about the disease and its remedy when such ideas are gravely advanced and actually acted upon. At the present time the whole of my seed is spread out thinly, and all the early varieties are laid singly upon shelves of open latticework. Already are the earliest varieties slowly making growth, each tuber having a stout shoot surmounted by its minute coronet of miniature leaves. Not one of them will be planted till next April, when the sturdy shoot, as thick as one's finger, will already have rootlets, and the tuber with all its vigour intact will send its stem to the surface in a few days, and both haulm and tubers will grow with such rapidity, and come so early to maturity, as to render success a certainty.—EDWARD LUCKHURST.

THE Royal Caledonian Horticultural Society have announced that a GREAT INTERNATIONAL FRUIT AND FLOWER SHOW will be held in Edinburgh in 1882. More than an ordinary amount of interest will attach to some of the classes at least, as the General Horticultural Company (Mr. Wills, manager) offer a prize of thirty guineas for the best six sorts of Grapes, two bunches of each sort, and a second prize of twenty guineas in the same class; also first and second prizes of the same value for collections of twelve sorts of fruit. Thus one hundred guineas are provided in four classes, which ought to stimulate cultivators to produce displays of unusual excellence.

— REFERRING to the prospects of THE CHRYSANTHEMUM SEASON a successful exhibitor informs us that from observation in several districts he expects the exhibitions to be uncommonly fine this year. The number of growers increases annually, and considerable skill is now brought to bear upon the culture, rendering the competition much closer and more exciting. The plants, too, are generally in good condition, the wood stout, foliage vigorous, and buds large and abundant.

— THE Municipal Council of Paris recently forwarded to the Lord Mayor of London, Sir Francis Truscott, AN ENORMOUS BOUQUET in acknowledgment of the courteous reception accorded to the members of the Council on their visit to the City a short time since. This bouquet measured nearly 9 feet in circumference, and was chiefly composed of Rose buds, White Lilac, Gardenias, Bouvardias, the bright blue Cornflowers, a few yellow and white Chrysanthemums, with a large outer circle of Cypripedium insigne backed up with Fern fronds. The arms of the city of Paris and the motto were cleverly delineated on the surface of the bouquet by an arrangement of red Rose buds and Cornflowers, every part being very clearly shown.

— ON the question of keeping BLACK HAMBURGH GRAPES the views of our correspondent "J. H. M." receive confirmation in an excellent article in the *Gardener*, which arrived after our correspondent's notes were in type. "There is," says our contemporary, "no doubt at all about the desirability of lengthening the season of Hamburgs as much as possible; for nine-tenths of those who own vineries for their own private supply, if polled on the subject, would vote for the Hamburg as long as it can be had, and for the other sorts referred to as short a time as possible, consistent with a supply. We have seen good late Black Hamburgs after the middle of February; but say that a month is cut off that, and to have them till the end of January is easily attainable; and we know of no point more desirable than that Hamburgs should be grown with this end in view, and that fewer late varieties should be planted."

— FURTHER experience with GILBERT'S CABBAGE BROCCOLI enables Mr. Muir to say that this is a valuable addition to choice vegetables. The flavour of it is delicious, surpassing that of any Cabbage he has tasted, and equal to that of Broccolis. It comes perfectly true from seed, and hearts freely and firmly under the same culture as any ordinary Cabbage. The Cabbage Broccoli is no doubt an excellent vegetable. Mr. Iggulden has sent us some heads, which when cooked were tender, sweet, and delicate in flavour.

— A CORRESPONDENT writes—"Among neglected plants few are finer than CHRYSANTHEMUM LACUSTRE. It will probably become as popular as Pyrethrum uliginosum has already done. The flowers are similar, but have the advantage of growing on a plant only about 2 feet high, requiring no support. The leaves are broad, strongly serrated, and very distinct from those of the plant with which comparison has just been made. In the Cambridge Botanic Garden it flowers just before that species, lasting several weeks. With liberal treatment it becomes very beautiful."

— A POTATO GROWER writes as follows:—"According to the evidence of Mr. Henry Thompson before the House of Commons Committee, it appears that he professes to have discovered a REMEDY FOR THE POTATO DISEASE. He does not state what it is nor the mode of application, but he is so confident of its efficacy that he is willing to undertake trials in any position north or south of London and with any varieties, and if the crops are injured he will pay for the damage and give his time for nothing. This seems fair, and I think it would be well if the opportunity were afforded him of proving whether the scheme really possesses any merit."

— THE exhibition of CHRYSANTHEMUMS in the INNER TEMPLE GARDENS, which we briefly referred to a week or two since, is now open to the public, and there are sufficient flowers to make a fair display, though they will not be at their best for at least a week. Several Japanese varieties have good representative blooms, those particularly noteworthy being James Salter, Gazelle, Cri Kang, Gloire de Toulouse, and the comparatively new Bouquet Fait, with large blooms, yellowish in

the centre and white outer florets. Among the incurved varieties the only one of unexceptionable merit as regards condition at present is the handsome Prince Alfred, of which there are some remarkably fine blooms. The well-known attractive and useful Gloria Mundi and Aurea Multiflora are also flowering very satisfactorily, and many others are rapidly advancing. We regret to learn that it was recently found some person had wilfully broken a number of the plants, plucking and destroying about five and twenty blooms. It is said that this is the first instance of the Chrysanthemums suffering from wilful injury since the exhibitions have been opened to the public.

— THE CHRYSANTHEMUMS IN THE MIDDLE TEMPLE GARDENS will be opened to the public during the ensuing week, but as they are rather late it will be some time before there are many blooms fully expanded. Eventually they may be expected to prove an attractive display.

— "A SALESMAN" sends the following observations concerning the LIFTING OF UNRIPE POTATOES IN CORNWALL:—"Mr. W. Roberts' note upon this subject on page 395 is liable to be misunderstood by those who are unacquainted with the facts. From what he says it would seem that growers in Cornwall practise early lifting with the object of avoiding loss by disease. This is not the case, however, for they simply take advantage of their favoured position and endeavour to send 'new Potatoes' into the London markets as early in the season as possible, knowing that they then realise the best prices. The majority of Cornish Potatoes are consequently lifted directly they attain a saleable size."

— MESSRS. JAMES CARTER & Co. of High Holborn have sent us a collection of flowers of their "CROWN JEWEL," strain of TUBEROUS BEGONIAS, which appear to be of great excellence. The flowers are large, of good form and substance, the colours being bright and diversified. The tints range from white through various shades of yellow, orange, scarlet, crimson, and pink. One flower of a bright scarlet hue was particularly notable for its symmetry, the petals being finely rounded. A yellow flower was similarly good.

— WE learn that ANTHURIUM ANDREANUM is now in flower at Mr. Bull's establishment at Chelsea, and thus an opportunity is afforded for those who have not seen this remarkable plant to observe its brilliant and singular spathe.

— WE are informed that valuable SILVER CUPS FOR ORCHIDS AND GRAPES will be offered at the Bath and West of England and Southern Counties Association's Show, which opens on June 6th at Tunbridge Wells next year, the horticultural department of which will, as usual, be under the able direction of the Hon. and Rev. J. T. Boscawen.

— THE third part of Messrs. Cassell's re-issue of "PAXTON'S FLOWER GARDEN" contains coloured plates of *Boronia elatior* and *Sarracenia Drummondii*, both fairly well representing the form and habit of the plants, but not quite faithful in the colouring. There is no cultural instruction accompanying the *Sarracenia*, though in the original edition a good system of culture was subjoined to the description of the plants.

— IN addition to the CHRYSANTHEMUM EXHIBITIONS which were noted last week, we learn that the following Societies will hold shows on the accompanying dates:—South London, November 15th to 17th; Ealing and Acton, November 17th; Tunbridge Wells, November 18th and 19th; Longton, November 22nd; Oxfordshire, November 23rd; and Manchester, November 25th.

— THE following results of EXPERIMENTS IN POTATO CULTURE have been sent to us by the Rev. A. Fitch, Thornton Steward

—"On March 12th, 1880, I planted a row of Potatoes consisting

of twenty-three varieties, row east and west; each set 15 inches apart, with a clear space of 3 feet on each side. I made a great mistake in planting indiscriminately instead of placing the varieties producing the smallest tops by themselves, consequently the coarser-growing varieties in some instances completely swamped those that were more delicate. This fact will in part account for great discrepancies in the different weights. The following were lifted on August 23rd—The produce of Suttons' Improved Ashleaf was 13 ozs.; Beauty of Hebron, 4 lbs. 3 ozs.; Porter's Excelsior, 3 lbs. 12 ozs.; Yorkshire Hero, 12½ ozs.; Pease's Red, 2 lbs. 6 ozs.; Snowflake, 2 lbs. 4 ozs.; Fox's Seedling, 11½ ozs.; Rivers' Royal Ashleaf, 2 lbs. 2½ ozs.; Lapstone, 1 lb. 14 ozs.; Gloucestershire Kidney, 1 lb.; Compton's Surprise, 2 lbs. 4 ozs.; Myatt's Ashleaf, 2 lbs. 4 ozs.; Rector of Woodstock, 4 lbs. 2 ozs.; Brownell's Beauty, 5 lbs. 11 ozs.; McKinlay's Pride, 5½ ozs.; Reading Abbey, 2 lbs. 12 ozs.; Schoolmaster, 1 lb. 11½ ozs.; Cambridge Kidney, 1 lb. 10 ozs. All were free from disease except one tuber weighing half an ounce of Rector of Woodstock. Lifted on September 21st—Early Oxford, 5 lbs. 14 ozs.; Woodstock Kidney, 3 lbs. 10 ozs. Lifted on October 1st—Suttons' Magnum Bonum, 8 lbs. 4 ozs. Lifted on October 23rd—Flourball, 8 lbs. 8 ozs.; Scotch Champion, 7 lbs. 2 ozs. Five diseased tubers of the latter weighed 1 lb. 4 ozs. All the others were free from disease. The produce of twenty-three sets weighed 5 stones 4 lbs. ½ oz. Two rows of Paterson's Victoria and two rows of Scotch Champions side by side at the Glebe, the former produced 18 bushels, more than half bad; the latter 25 bushels, and not a pailful of diseased tubers."

— THE RECENT HEAVY RAINS.—The rainfall of October was excessive, amounting at Addiscombe, Croydon, to 7.648 inches, or nearly one-fourth of the total amount deposited during the whole of last year. Throughout the twenty-one years over which the Croydon records extend there is no other instance when so much rain fell in any single month, not even excepting the December of 1876.—E. M., Croydon.

THE GLADIOLUS.

THE date of the introduction of the Gladiolus I have had no means of knowing, but seventy years ago we only possessed the following forms:—*G. byzantinus*, purplish crimson; *G. cardinalis*, scarlet and white; *G. communis rubra*, red; *G. communis alba*, white; and *G. floribunda*, white and rose. These were the only forms in cultivation previous to about 1830, when from being a large importer of Dutch bulbs I received a corm of a seedling Gladiolus called *Ramosus*, which was catalogued at 10s. Not knowing much of the Gladiolus I sold it to a nurseryman for 7s. 6d. The year following another came and shared the same fate. Years passed on and *G. gandavensis*, the parent of most we now possess, next made its appearance; its colour was not very bright, and it did not meet with much attention. A few years later Mons. Souchet of France sent me a printed catalogue, which after some time I gave to a friend, and he had the spirit to order a small case, and thus they were introduced into Lancashire. The prices then ranged from 1s. to 6s. per corm. They attracted some little notice, and the following year there was quite a demand for them, which my friend had the greatest difficulty in supplying. Only a few were really attractive; yet I purchased about a score of corms, but not of the best, as the prices deterred me, but the two following years I improved my collection. The autumn was favourable as respects weather, and I had a very large crop of seed. Some of the spikes had no less than twenty-two or more pods.

The year following I sowed the seed, one half in boxes in a cold frame and the other half in a bed, but I could see no difference in the size of the corms when at maturity. The quantity of corms was very large—nearly three thousand, and I had to obtain a plot of ground to grow them in, which ground I trenched 30 inches deep, and applied manure abundantly. I planted my corms in this soil not quite 3 inches deep—some growers recommend 6 inches, but I always found that 3 inches from the crown of the corm was quite sufficient. I was able the second year to exhibit at the Middleton Agricultural Show, and also at the Stockport

Floral and Horticultural Society. They grow best in a richly dunged bed, and fine spikes may be obtained which will gratify the most fastidious florist. I cannot conceive why a flower so brilliant in colours should only be grown by few, and also at a time when flowers are not very plentiful; they require so little trouble and form a great ornament to the shrubbery when planted in clumps of six or eight together, taking great care to blend the colours well. The *Gladiolus* produces seeds freely, and if seed is required it is well to shelter them from the rain and gather the pods as they ripen.

I have omitted the result of my seedlings, as I only took seed from the best of the varieties, and in doing so I discarded all faulty varieties, and the result was I had not many to dispose of, and for those I obtained 15s. per hundred. I had a great number of varieties equal to any raised in France, and not a few of different shades and colours—quite a new style. I find from last year's catalogue that the prices for corms have been greatly reduced, and what I then gave 6s. or 7s. each can be bought for 9d. to 1s. each. The following are a few that I should recommend to be grown in order to raise seedlings:—

Light-coloured.—Bertha Rabourdin, pure white; Madame Binder, white; Marie, pure clear white; Reine Victoria, pure white, broadly feathered with deep carmine; Penelope, creamy white shading to blush; Rebecca, white lightly shaded with lilac, deep carmine.

Scarlet.—Comte de Morny, splendid vermilion; Duc de Malakoff, brilliant orange scarlet with pure white veins; Fulton, rich transparent vermilion red; James Veitch, bright vermilion, striped violet; La Titien, bright vermilion; Meyerbeer, intense brilliant, scarlet of petals flamed vermilion; Sir Joseph Paxton, brilliant orange red, lower petals white.

Rose.—Calendulaceus, pale salmon rose shaded with deeper rose; Diana, delicate blush shaded with rose, lower petals striped bright carmine; Jeanne d'Arc, blush shaded with pale rose, lower petals striped with deep carmine; Lord Raglan, salmon rose, lower petals striped deep vermilion; Madame Furtado, most beautiful, blush flamed with rosy carmine, &c.; Madame Vilmorin, deep rose shading to blush, lower petals striped with carmine; Mazeppa, bright salmon rose; Milton, beautiful blush rose, lower petals striped with crimson; Oracle, brilliant cerise rose with deeper shades; Valleda, delicate rose shaded with carmine.

Gladioli may be grown to advantage in pots; when planted in beds the corms should be 6 inches apart.—JOHN SLATER.

THE POMOLOGICAL MEETING AT HEREFORD.

THE fourth annual Exhibition of the Pomona Committee of the Woolhope Club was held at the Free Library, Hereford, on the 27th and 28th ultimo; and this was by far the most attractive and satisfactory of any of those that preceded it. Four years ago, when the attempt was first made to bring together representatives of the many varieties of Apples and Pears cultivated in the Herefordshire orchards, the object was mainly to ascertain what varieties were best adapted as vintage fruit for the manufacture of cider and perry. The old historical varieties, it was said, had died out, and their places supplied by modern kinds inferior in merit either as pot fruit or for vintage purposes; and the Committee of the Woolhope Club, with the praiseworthy energy which this Society always exhibits, made this a subject for investigation. At the first meeting the number of plates shown did not exceed three hundred, and these included a large number of dessert fruit grown in the gardens of amateurs; still there was a fair representation of the cider and perry fruit—quite enough to show the miserable state the formerly renowned Herefordshire orchards were in through negligent cultivation, and the total absence of any regard to the varieties of fruits best calculated to add to their wealth and reputation. Not much interest was manifested at this first Exhibition, though there were some—and fortunate it is that there are always some who are ready to assist in any good work—whose names will be on record, and who came forward and lent a helping hand in promoting the desirable object. Since then the interest in the subject has spread, and year by year the Exhibition of the Pomona Committee has become one of the annual events of the county, till it has attained a magnitude which bids fair to become too great for the limited accommodation the Free Library affords. On this occasion there were but few short of two thousand dishes of fruit exhibited.

As might have been expected such a work could not long be confined to vintage fruit only, and in each succeeding year we find that dessert and culinary fruit have rapidly increased, while the area of competition has widely extended. Not only do the adjoining counties of Worcester and Gloucester send their contributions, but the distant orchards of Kent and Devonshire have their representatives. Berkshire puts in a creditable appearance, and far distant Normandy stretches out a hand, renewing the ancient connection which gave to Herefordshire so many of her original Apples and a knowledge of orcharding.

At the first two Shows there was no competition, all the specimens being exhibited gratuitously, and out of a laudable desire to assist in

obtaining and diffusing information on the orchard fruits of the county. It was soon found, however, that to maintain an annual exhibition and to obtain still further information on the subject it was necessary to hold out some inducement for growers to send their specimens, and the usual recourse was adopted of publishing a schedule with prizes. This seems to have become an established custom, and this year the schedule extended to thirty-nine classes, with a prize list amounting to £51. The first four classes were for professional growers, and in these the prizes for dessert and culinary Apples were carried off triumphantly by Mr. Lewis Killick, Langley, near Maidstone. In Class 1, for dessert Apples, he exhibited Lady Derby (Summer Thorle), Duchess of Gloucester, Worcester Pearmain, Yellow Ingestre, Old Nonpareil, Warwick Pippin, Cox's Orange Pippin, Duchess of Oldenburg, Court Pendu Plat, Hubbard's Pearmain, Aromatic Russet, Mattot's Pearmain, King of the Pippins, Sharp's Pippin, Ribston Pippin, Sturmer Pippin, Border Pippin, Royal Russet, Dungan, Margil, Golden Russet, Court of Wick, Fearn's Pippin, Mannington's Pearmain, Golden Knob, Bordeaux Reinette, Wanstall, Scarlet Nonpareil, and Blenheim Orange. The second prize was very creditably taken by Mr. J. Watkins of Wistaston, and the third by Mr. J. Griffiths of Tillington. In the class for culinary Apples Mr. Killick carried off the first prize with Bedfordshire Foundling, Loddington Seedling, Warner's King, Tower of Glammis, Beauty of Kent, Winter Nonsuch, Gooseberry Pippin, French Royal, Cullen, Hanwell Souring, Norfolk Beefing, Woodcock, Queen Charlotte, Winter Quoining, Blenheim Orange, Lord Derby, Hoary Morning, Royal Russet, White Apple, Seely's Apple, Yorkshire Greening, Mère de Ménage, Lucombe Seedling, Wellington (Dumelow's Seedling), Cox's Pomona, New Hawthornden, Golden Noble, King of the Pippins, Lord Suffield, Graham, Golden Spire, French Crab, Northern Greening, and Ecklinville Seedling. The second successful competitor was again Mr. J. Watkins, and the third Mr. John Barnes of Gloucester. In Class 3, for dessert Pears, the first prize went to M. O. Benoit of Havre, France; the second to Mr. H. Moorman, Tivoli Gardens, Cheltenham; and the third to Mr. Barnes of Gloucester. In Class 4, for culinary Pears, Mr. Barnes was first.

The amateur classes were keenly contested, but Sir H. Scudamore Stanhope, Bart., of Holme Lacy, shot far ahead of them all, especially in dessert Pears. In the class for dessert Apples he was first with very fine Ribston Pippin, Blenheim, Newtown Pippin, Pine Apple Russet, Ashmead's Kernel, King of the Pippins, Cox's Orange Pippin, Margil, Golden Harvey, Royal Russet, Court Pendu Plat, and Lamb Abbey Pearmain. Mr. John Pitt of Bosbury was a good second, and Mr. H. Jenkins, Nupton House, Canon Pyon, was third. In Class 6, for culinary Apples, Sir H. Scudamore Stanhope was again first with Gravenstein, Blenheim Pippin, Cellini, Gloria Mundi, Winter Hawthornden, Dumelow's Seedling, Warner's King, Tower of Glammis, Small's Admirable, and Alfriston. Lady Emily Foley of Stoke Edith was second, and Mr. Higgins of Thingehill was third. In class 9, for not less than five dishes of dessert Pears, Sir H. Stanhope was first with a splendid collection of choice assortment and meritorious cultivation. They were Doyenné Gris, Beurré Bachelier, Easter Beurré, Glou Moreau, Doyenné d'Alençon, Doyenné Blanc, Beurré d'Aremberg, Beurré Superfin, Triomphe de Jodoigne, Beurré Diel, Duchesse d'Angoulême, Zéphirin Grégoire, Van Mons Léon Leclerc, Beurré Sterckmans, Columbia, Doyenné Boussoch, Doyenné du Comice, Beurré Clairgeau, Monarch, Duchesse d'Orléans, Marie Louise, Josephine de Malines, Général Todtleben, and Beurré Bosc. J. Booker, Esq., of Wisington Court, Ledbury, was second, and Lady Emily Foley of Stoke Edith was third. Class 10 was for dessert Pears, not less than three varieties, and here Sir H. S. Stanhope was again first with twenty-one varieties, most of which were in the former class, with the exception of Beurré Hetterick, St. Germain, and Ne Plus Meuris. Mrs. Evans, Moreton Court, Ledbury, was second, and Rev. C. H. Bulmer of Credenhill was third.

From Classes 12 to 29 they were all open either to professional or amateur growers. In the former, which was for dessert Apples for present flavour, Charles Eyre, Esq., of Welford Park, Newbury, Berks, and J. Somers Cocks, Esq., of Great Marlow were equal first, the former with Margil and the latter with Cox's Orange Pippin. Class 13 attracted great interest. It was for a plate of five culinary Apples to be judged for size, weight, and quality. In each case the variety shown was Warner's King, and there was perhaps never better examples shown. The first prize was awarded to H. Higgins, Esq., of Thingehill, whose five fruit weighed 7 lbs. 3 ozs.; the second to Mr. L. Killick, his weighing 5 lbs. 7½ ozs.; and the third went to Mr. Bennett, Sutton Hill, Hereford, the five weighing 4 lbs. 12¾ ozs. Classes 14 to 19 inclusive were for single dishes of specific varieties, but they did not draw forth anything that calls for special notice. Class 20, dessert Pears for present flavour, produced a confirmation of the high merits of Thompson's and Seckle, the former being shown by G. H. Piper, Esq., of Ledbury, who took first prize, and the latter by Charles Eyre, Esq., who was second. Rev. C. H. Bulmer had specimens of Doyenné du Comice of very high character, but unfortunately his plate was one short of the required number and could not compete.

The class for culinary Pears for size, weight, and quality excited, like the culinary Apples, a considerable amount of interest. The variety was Uvedale's St. Germain, and the first prize was awarded to H. B. Strangways, Esq., Shurdington near Cheltenham, the five

fruit weighing 7 lbs. 14 ozs. M. Benoit was second, his weighing 6 lbs. 8 ozs.; and Mr. Barnes of Gloucester was third, his weighing 6 lbs. 7 ozs.

As was natural, the classes including the vintage fruit had a particular attraction for Herefordshire growers. In the class for early varieties of cider Apples Mr. Watkins of Wistaston, Mr. Hill of Eggleton, and Mr. Grove of Tupsley were respectively first, second, and third, and Mr. Davis of Venn's Green, Hereford, had an extra prize. For the late varieties of cider Apples Mr. John Watkins was first, H. Jenkins, Esq., of Canon Pyon second, and Mr. Hill of Eggleton third. For the collection of perry Pears Mr. John Watkins was first, Mr. John Ford, Withington, second, and Mr. W. Hill of Eggleton third. Prizes were offered for cider Apples not grown in Herefordshire, the first being taken by Mr. Randell of Devonshire, and the second by Mr. Barnes of Gloucester. For the perry Pears not grown in Herefordshire the first was taken by Mr. Barnes of Gloucester, the second by H. B. Strangways, Esq., and the third by Mr. Charles Ford, Pitt House, Dymock.

We observed a large quantity of that beautiful Apple the Worcester Pearmain, exhibited by Messrs. R. Smith & Co. of Worcester. These were not for competition, nor was a miscellaneous collection of Apples sent by the Cranston Nursery Company.

With the exception of four classes for cottagers the above formed the substance of this most interesting Exhibition. Among the advantages that are derived from bringing together these collections of fruit, one of the most important is the opportunity it offers for selecting specimens for the "Herefordshire Pomona," upon which the Woolhope Club have concentrated so much energy. All over the room might be seen tickets intimating that the dish has been selected by the Pomona Committee for supplying portraits of fruits to the "Pomona," and it never happens that the request has been denied. Thus it is that this magnificent work is supplied with faithful representations of the fruits which it illustrates.

Two special prizes were offered by Dr. Bull, one for the largest Pear in the Show, which was taken by Uvedale's St. Germain, weighing 1½ lb.; and the other for the largest Apple, which was taken by Gloria Mundi, weighing 1 lb. 11 ozs., and measuring 16 inches in circumference, both exhibited by M. Benoit of Havre, France.

It is but justice to record the untiring application given to this Exhibition by the two Honorary Secretaries, Mr. Reginald Symonds and Mr. Henry Moore, ably assisted as they are by Mr. D. R. Chapman, the Librarian of the Free Library.

DISASTROUS GALE.

FOLLOWING the severe weather of the previous week, 14° below freezing point having been registered at 4 feet from the ground on the morning of October 20th, and 12° below freezing point on the 24th, snow, sleet, and hail falling more or less during the week in fitful showers. The weather set in bad at noon on Wednesday, October 27th, rain falling heavily, intermingled with snow and hail, continuing through the night with the wind north-east and blowing strongly. By nine o'clock on the 28th 2.13 inches of rain were recorded; and by noon, or during the previous twenty-four hours, 2.85 inches of rain had fallen, the wind continuing a hurricane from the north-east, reaching its strongest blast at about 11 A.M., when it drove through plantations of Larch, Scotch Fir, and Pines, laying them as flat as if felled, also doing great damage amongst those of about a dozen years' growth. Large trees of Scotch Fir and Larch were uprooted, tons of soil being upheaved with the roots. Austrian Pines were in some instances snapped off at the ground, those and Scotch Firs having suffered the most. Corsican Pines are also anything but perpendicular, and specimens of Cupressus Lawsoniana about 20 feet in height were blown down. Spruce, especially young trees, have fared better, but many over 100 feet in height are down. The saturated state of the ground no doubt aided in the downfall of the trees, the devastation among trees being very great along the coast of the North Riding of Yorkshire.—G. ABBEY.

GROS MAROC GRAPE.

THIS very imposing Grape, a portion of a bunch of which is represented in fig. 78, was obtained by Mr. Rivers in 1850 from M. Vibert of Angers, a very enthusiastic and skilful viticulturist, who raised and sent out many seedlings, but did not raise the variety in question. A Vine of the Gros Maroc grown in a pot in a forcing house at Sawbridgeworth first attracted attention by its great fertility, and the colour and late-keeping properties of the fruit. As soon as room could be given it was planted out in a vinery, and it has now developed into a very valuable black late-keeping Grape. The berries are large, deep blue black, carrying a very dense bloom, flavour very sprightly and rich. It is rather singular that when grown in a pot the Vine produces bunches at every joint, but when planted out the growth is so vigorous that it will not submit to spur-pruning; Mr. Rivers therefore recommends growing it on the rod or extension system.

Gros Colman was sent to Sawbridgeworth by M. Vibert about 1848 as a present, and being a "gift horse" was not much thought of for many years, but its hidden virtues have at last brought it into notice as one of the largest late Grapes. Gros Maroc has gone through the same career, and its merits are now recognised. Like the Black Hamburg the fruit of the variety in question is not likely to cloy the palate, and it is no worse for being an old

Fig. 78.—Gros Maroc (part of a bunch).

variety. It was first exhibited at one of the meetings of the British Pomological Society—namely, in August, 1857. The fruit was in an unripe state. The variety was then determined to be the Damas Bleu, Gros Damas, Merbregie, or Gros Maroc, which was grown and esteemed in the south of France for its fine appearance and good quality. It is known in Italy as Uva Damascena.

BURNING CLAY.

OF the value of burned clay or charcoal soil there can be no doubt whatever, and the plan recommended at page 380, as having been practised by Mr. David Thomson, was, of course, successful, or that excellent cultivator would not have advised others to follow it. But times have changed since Mr. Thomson was gardener near Barnet, and I question if there are many landlords now who would consent to pay for burning soil 2 feet deep. If anyone contemplates doing such a thing and thus benefiting many future generations, he had better count the cost first, for it is something very considerable; and if the work can be only half done little or no good will result, and it is worth considering whether the desired end cannot be attained by another and less expensive method.

I know a plot of ground on which something of the kind was attempted many years ago. Much labour was spent on it and a great amount of fuel was burned; but as the work was not done

thoroughly all the expenditure was thrown away, and that particular plot is worse in some respects now than others which were not taken in hand. Mind, I admit that the work when well done is almost a perpetual benefit; but what would be the cost per acre, or in other words what would be the cost of excavating, wheeling, burning, and wheeling back again some 3000 cubic yards of clay? And how many years of the extra produce would it take to pay for the outlay? The cost of wood would have to be reckoned now-a-days as well as the labour, for there is very little wasted on a well-managed estate where charcoal has to be made, and where everything worth tying up is made into faggots for sale. I have some 8 acres of heavy soil under the spade, and am well aware that a larger expenditure on it would produce more satisfactory crops of some kinds, and in the course of time the expense of working it would be lessened, but I am certain that were I to do one acre of it this season on Mr. Thomson's plan I should not be allowed to remain to see the result. For all this I have little doubt that I burn as much clay as most gardeners do, and can show a very material improvement effected by it every season.

I maintain that if a subsoil, whatever its nature, cannot be brought into a thoroughly good working condition on account of cost or otherwise, it is better not to disturb it at all, for 12 inches of surface soil will yield more satisfactory crops when only cultivated to that depth than will 24 inches if half of it consists of either clay or sand. Many a piece of fertile ground has been rendered sterile simply by the act of trenching; and I have long since come to the conclusion that unless the soil can be made rich and sufficiently porous to admit air constantly to the depth it is cultivated, that deep cultivation is a mistake. Burning the soil to the depth of 2 feet would render the soil permanently pervious to air, but burning it to the depth of 1 foot would not do that; and I imagine that 4 inches of burned clay spread on the surface, and dug in without disturbing the subsoil, would at a less expense be more satisfactory. That is the plan I follow and which, seconded by liming, is gradually bringing about a very great difference in the texture of the soil. When the burning is done on the quarter there is no choice of time for the operation; it must be done when the crops come off, whether other work is pressing or not, and whether the ground is wet or dry.

I practise having a good heap, some 600 or 800 yards, burned outside the garden every winter, to be wheeled on and used where most required all through the season. The management of the fire cannot be better described than it is done at page 380, except that we do not keep it round. It is generally square or oblong after it has been alight two or three weeks, and we enlarge the base on one side at a time as it is required. Managed thus, we find two or three men sufficient to keep it going, except when it occasionally breaks out more fiercely than usual and on Saturdays, when it requires an extra banking-up.

The larger the fire becomes at the base the less is the comparative cost of burning, as it takes less wood, and the clay can be merely wheeled on the top and tipped without much spreading. Stumps of shrubs, roots of rushes, coarse grass and weeds, are a great assistance, as they do not lie so close as the clay, and admit air into it. I had a heap burning six weeks last winter, and there is scarcely a day but some of it is used for some purpose. The stock is now getting short, and I hope soon to be able to start afresh. There is no lack of clay close at hand, indeed we have too much of it.—WM. TAYLOR.

THE POTATO DISEASE AND RAINFALL.

I THINK your Lincolnshire correspondent must be a canny Scot, for instead of answering the queries I suggested to "INTERLOPER" he asks me a question. Some time ago, according to *Punch*, when a Scotchman was asked which was the way to Glasgow, he replied, "I guess ye are frae Lunnun." But these queries must be answered by those who wish the rainfall theory to be considered. Why was it the Potato was cultivated in Great Britain for about two centuries before 1845 and no injury whatever done by excessive rain, but in that year the mischief began, and has continued ever since? This is the little difficulty; it is the *pons asinorum* of the Potato disease subject. No matter how ingenious the theory or how elaborate the argument, unless you can answer this question all is labour in vain. At the same time I will for the present pass that over, and go to the other side of the question, and look at "LINCOLNSHIRE POTATO GROWER'S" query. I do not know really that I need say much or take much trouble to answer his query, for anyone who reads carefully the first part of his letter, and then the conclusion, will see that he answers himself in the last few lines. He brings forward this wonderful fact about the disease being so bad in wet years, and comparatively none (he

does not mean this literally) in others, as though I had ever said the contrary, when such is certainly not the case. The disease is undoubtedly worse as a rule in Gloucestershire as well as other counties in wet seasons than in dry, but that is a very different thing from the rain being the cause or origin of the disease. When children go to school suffering from scarlet fever, other children are liable to take it; in fact the spread of the disease is so much promoted by schools that the sanitary inspectors very often close them. Would "LINCOLNSHIRE POTATO GROWER" say that schools were the cause of scarlet fever? I do not suppose he would. Then, again, with regard to rain alone being the cause of the disease, your correspondent is in error in saying that wet seasons are invariably the worst. The year 1879, which was the wettest of this century, will long be remembered for its disastrous effects on the Potato crop as well as other crops, but the next wettest in the century—viz., 1860, which very closely resembled 1879, was a remarkable exception, for there was not much disease. How does "LINCOLNSHIRE POTATO GROWER" propose to account for this exception? Perhaps he will say that he never intended to infer that rain alone was the cause of the disease; if that is so I fail to see the point of his argument or his object in writing the letter. Perhaps I may reply to "INTERLOPER'S" queries next week.—AMATEUR, Cirencester.

KEEPING GRAPES.

THE remarks on the above subject by Mr. William Taylor were, I think, fitly placed as a leader in your Journal. I do not know that I should have troubled you with my remarks, but that twice within the last fortnight I have been spoken to personally on this matter. I fully agree with what your correspondent says except this—I always prefer to water my Vines on a fine day, early in the morning if possible, so that before night the surface soil may be moderately dry. I believe that Grapes are not prevented keeping well so much by a house being wet when they are hanging as by their not being well ripened. To keep Grapes late they must be well ripened by the middle or the end of September. Then, again, they must be well coloured to keep: bad-coloured Grapes are always the first to damp. My rule in keeping Grapes is to water the borders during the fine days of October, so that in the dull damp days of November the house may be kept dry, but not so dry as to injure the roots. I know from my own observations that nothing renders the buds plump better than a judicious liberal supply of water in the winter, even when the Vines are supposed to be at rest. In watering, where Grapes are hanging, particular attention is required in ventilating, and it is always well to keep the ventilators open a little at the top of the house; thus the heat in pipes will ensure the damp rising. In sunny weather ventilate freely. No greater mistake can be made than in supposing Grapes can be kept without fire heat, even though they may be grown in a fine season without it. I have grown Alicante weighing 2 lbs. the bunch this year without fire heat, but the Vines were planted this March, so I only had two bunches to a Vine. I started the fire to ripen the canes.

My plan with late Grapes is to start the Vines the first week in March, so as to have them really in advance of the season, for it is no use depending on fine autumns for ripening purposes. No amount of fire heat now will colour Grapes. In my earlier days it was a matter of surprise to me to see late Grapes as a rule do so well, but I believe the great secret to be in the fact of having heat in the house in the autumn; this, while keeping the fruit, at the same time ripens and hardens the wood. In all the houses here I planted the Vines in front of the pipes, believing this to be beneficial. I will here say I am no advocate for filling late vinteries with plants; in any case no plant should be directly under the Grapes. In lean-to late houses I have kept Strawberry plants on a back border through the winter, and these I always keep well watered. In span houses a considerable number of plants may be kept on either side of the walk without encroaching. The bunches must be well thinned, and as soon as the Grapes are well finished gradually remove small laterals so as to admit air and light. Then with regard to cutting fruit, I am always content to clear out by the end of January, though I have by way of experiment kept Grapes until the first week of March before cutting, but nothing is gained by so doing. I may also say that had I a fruit room I should certainly prefer a dry floor. I do not know that this is really necessary, but I incline to a dry floor. I do not intend naming the best varieties here, but I have kept a whole house of Black Hamburgh for Christmas, and would do so again rather than put them in the market when the price is low. The Gros Colman is a Grape that is now exciting much attention, and justly so; but I fear many will fail with it, for it requires plenty of heat, well thinning, and

extra attention.—STEPHEN CASTLE, *The Vineyard, West Lynn, Norfolk.*

CHAPTERS ON INSECTS FOR GARDENERS.—No. 14. NEW SERIES.

THAT the name of Rove beetles should be distinctive of one group amongst the Coleoptera may appear odd, for the majority of beetles, even amongst those that are fond of darkness and secret retreats, display a propensity for roving in their perfect state. This appellation, however, particularly suits several of the species in the family now to be noticed, because they often attract observation from their habit of moving rapidly across beaten paths and open places with a very determined air, evidently either in the act of hunting for prey, or on the road to a spot where they expect to obtain it. These are prominent species in the division of Brachelytra, which embraces some large species and some that are quite diminutive. Beetles that have short wing-cases is the meaning of the scientific name, and it points to a marked peculiarity in this, the last division of the group of Rhypophaga, or Filth-consumers; though there are occasional examples of a similar habit in beetles that are classed otherwise, owing to their structure. The Devil's Coach-horse is an inelegant and not very appropriate name applied to more than one sombre-looking species belonging to this group, but probably it is most frequently given to the common Rove beetle that is properly named *Ocypus* or *Staphylinus olens*. One naturalist, indeed, asserts that this phrase is appropriate, and says that he made a magnified drawing of this beetle with head erect and sparks of light coming from its eyes, which his friends generally took for a fancy sketch of an imp. But then the epithet implies that the creature is a representative of one of his Satanic Majesty's steeds. Certainly it is black enough in hue, yet other beetles resemble it in this respect, and some can run much faster than it can. So that, as I presume, the epithet was suggested by the supposed viciousness of the insect, shown by its threatening attitudes, coupled with its mode of locomotion, for many crawling beetles that take flight if touched, or feign death. Not so *Ocypus olens*. The insect is doubly armed, in front and rear; therefore when attacked it raises the head with its sharp mandibles, and also lifts the tail, at the end of which are two glands, from which it can eject a liquid of extremely unpleasant odour. Cocktails is yet another name for *O. olens* and his brethren, originated by this peculiar movement of the tail—an action not always pugnacious, since some of these beetles use it with great dexterity to fold up the wings under the short wing-cases, should they have flown along, as they are capable of doing, though not fond of thus taking the air. But this particular species is one of the useful insects, despite its evil aspect (though after all there is some beauty in the polished black head and grey downy wing-cases), for it kills many other insects that are feeders on vegetables, and also looks out specially for earthworms. These the beetle chases even into their burrows; but it has been observed that when an earthworm, as it often will, drags a portion of a leaf within the mouth of its hole, a Rove beetle, for some reason or other, does not enter in pursuit. In the larval state *O. olens* is equally predaceous, and resembles the mature beetle somewhat, in size less of course, and lacking wings; it is occasionally found in combat with one of its own kind.

The history of this Cocktail, a familiar species, has been dwelt upon as a sample of that of others allied to it, in varying degrees destructive to injurious insects of the garden both as beetles and as larvæ. In one or two species the larvæ dig tunnels formed after the manner of the tiger beetles, into which they drag unwary wanderers, seizing them by the head and sucking their juices. Some of the lesser beetles amongst the Brachelytra reside in the nests of ants, at least occasionally; and it is thought that the ants carry them into their abodes and keep them prisoners in order to feast upon a liquid exuded by the beetles—doing with them, in fact, just as with the aphides. It does not appear that the ants kill their prisoners, even if they have become of no use to them. The species of *Claviger* are supposed to live entirely in ants' nests, and they are eyeless, so their structure is adapted to their circumstances, whatever food they require being obtainable in their singular abode, if it is not actually supplied to them by the ants.

The division of beetles we now proceed to has within it numerous large and conspicuous species, the dung beetles and the chafers are examples; and the majority of the insects are vegetarians, attacking very frequently the growth of our gardens and fields. These, the Lamellicornes, while they have, like all the divisions that have been noticed, tarsi that are five-jointed, are distinguished

by the termination of the antennæ, which is in the form of a club. This club is either toothed, or else jointed and composed of tiny leaflike blades. Largest of our British beetles, and at the head of this division, we place the stag beetle (*Lucanus Cervus*), an insect which from its bulk and usual habits has become well known to many who are not naturalists. The male insect flies in or near parks and shrubberies, or exposes itself to view by promenading upon the top of a paling, where persons see it, but are disinclined to handle it on account of the formidable horns. These, possessed only by the male insect, are really the enlarged mandibles, but weakened, for although the beetle can nip with them, their pressure is scarcely felt. The female, less seldom seen, and not popularly recognised as the better-half of the monarch of our beetles, has, however, a biting apparatus much more effective employed to introduce her eggs deep into the solid wood of trees. In size she is rather less, and it is she that should be sought particularly whenever the ravages of the larva render it necessary to put a check upon the increase of the species. Some folks that suggested that it was this larva, and not that of the goat moth, which was called the "Cossus" by the ancients, a worm or grub found within trees, and cooked up as a delicacy. I would only say that if the Romans could eat with relish either of these larvæ they must have had singular appetites. As the larva of the stag beetle grows slowly—its life lasting two or three years, possibly

Fig. 79.—*Ocypus* (*Staphylinus*) *olens*.

longer—it consumes much wood, boring extensive tunnels in the heart of Willows and Oaks chiefly. The head has a curious aspect, having a horny transparent ridge in front, through which can be discerned the working of a pair of powerful jaws.

That common beetle called the "Dor," or the "Watchman," with occasionally an adjective preceding, having emphatic reference to the parasites, properly *Acari*, which adhere so firmly to his under surface, is rather useful than injurious to us. His name of *Geotrupes stercorarius* announces that he occupies himself in labours on or beneath the earth, amidst dung, too, yet his shining coat of mail is seldom soiled unless by an accidental downfall. For when he is upon the wing (and this is not only at night, but sometimes during the day), he has seemingly not much skill in guiding himself, and so comes often to the ground by striking incautiously against some object in his line of movement. The sonorous hum made by this and other dung beetles may perhaps serve to protect them from the attacks of birds. As we have repeatedly seen individuals of *G. stercorarius* about in all the warmer months of the year from April to October, there must be either an emergence in succession of the beetles, or their life exceeds that which usually belongs to the imago state of these insects. The larvæ doubtless live for many months in the peculiar nutriment that shelters and feeds them. It is only necessary to take up one of the dung beetles, small or large, and placing it in the palm, then close the hand a moment, to be convinced about the muscular strength that resides in the thorax and legs. Small

heaps of manure scattered over the ground offer great attractions to the genus *Geotrupes*, and the beetles by burying portions of this, which the larvæ subsequently divide, assist, we would think, in the fertilisation of the soil. Was it for this reason that the Egyptians worshipped the antique *Scarabæus*, a near relative to these?

BRISBANE BOTANIC GARDENS, QUEENSLAND.

THE drought of 1877-8 was succeeded by twelve months during which the rainfall was about 9 inches above the average of the preceding twenty years, and there were several storms, two of which were of great force and caused much injury. Rain fell on 148 days, to the amount of 60.28 inches. The last season was also more than usually wet, but there were no destructive storms. During the past twelve months 58.45 inches of rain fell on 146 days.

The borders along the line of walks and the plots facing the aquaria were planted with *Agave*, *Yucca*, *Bromelia*, *Sansevieria*, and also *Allamanda*. Many of these shrubs which had grown too large for their station have been removed to more favourable situations, and in the summer and autumn months the many coloured varieties of *Amaranthus*, *Coleus*, &c., were planted in the vacant places, which added to the general effective appearance. Upon the same slopes are the Tea, Coffee, Cinnamon, and Cotton plants; the compartment containing the *Macrozamia*, *Cycas*, *Bowenia*, *Stangeria*, *Cataglyphis*, and *Encephalartos*. The beds and clumps are filled with *Cocos*, *Sabal*, *Oreodoxa*, *Latania*, *Pandanus*, &c., and to the north of the Tea plantation is the collection of Palms much noticed by writers who have visited us from the southern colonies and other countries. To these latter have been added *Calyptronoma Swartzii* (the Long-thatch Palm of Jamaica), *Sagum amicarum* (the Vegetable Ivory Nut of the Solomon Islands), *Brahea dulcis* (the Sugar Palm of Mexico). They are all thriving exceedingly well. The plots, borders, &c., have lately been dug over, and have received a good supply of manure.

The rosery has undergone a thoroughly deep digging and dressing with a strong loamy soil from the site where the new building for the Port Master's Department is being erected. Forty-eight new varieties of Roses have been added to the collection, principally of the Tea and Noisette sorts, which I find are best suited to this climate. From present appearances they promise a good supply of flowers.

The following interesting plants have flowered and fruited during the past season:—*Spathodea campanulata*, *Chrysophyllum imperiale*, *Toxicophlæa spectabilis*, *Poinciana regia* var. *lutea*, *Ptycosperma Hilli*, *Kentia minor*, *Quercus suber*, *Vanda Batemani*, *Saccolabium Hendersoni*, *Saccolabium giganteum*, *Dendrobium Bensoni*, *Dendrobium Falconeri*, *Phalaenopsis grandiflora* var. *lutea*, *Cypripedium Stonei*, *Cypripedium Parishii*, and *Grevillea Palmeri*.

Amongst the fruit-bearing trees the most interesting is the Black Peach introduced from Japan in 1878. The fruit is about the size of a duck's egg, the flesh of a dark reddish colour, juicy and of good flavour, and free from all disease. Grafts or buds of this valuable tree can be had on application.

Several well-managed nurseries are now to be found in Brisbane and elsewhere in Queensland. The time appears to have arrived when it would no longer be fair to the enterprising proprietors of those establishments for an institution supported by the public revenue to distribute gratuitously seeds and plants that can be purchased at a reasonable cost within the colony. This does not refer, of course, to useful imported plants that are not to be bought here, or to others which the Government may consider advisable to be given away in order to aid in the establishment of new industries.

The International Exhibitions of Philadelphia and Paris received large and valuable collections of timbers, fibres, cereals, arrowroot, sugars, essential oils, specimens of indigenous grasses, none of which were returned here, and nothing whatever received in the way of exchange. Whatever advantages may have otherwise been derived, this establishment has not reaped any of the benefit that was anticipated. Our whole resources were strained, and the routine work very much interfered with, and not as much as a single specimen for the herbarium or museum was got in return. Of the collection since contributed to the Sydney International Exhibition, many things were either retained there or sent back in a useless condition. There were 234 economic plants forwarded, one-half of which, and several manufactured products, were applied for and given to the Director of the Sydney Botanic Garden, upon the condition that he would send back an equivalent collection in exchange. Not only has he failed to do so without affording any explanation, but has also "taken charge," as I am informed, of the other half of the economic plants and of several exhibits belonging to this establishment which it was very important should be returned. A list of these has been forwarded to the Department of Public Lands. Under these circumstances I have had to begin getting together a fresh general collection for the approaching Melbourne Exhibition. It was my intention to have made it a display of the vegetable resources of Queensland on a larger scale than ever yet been seen, but the result must now be expected to fall short of my original idea. I mention the above facts in order that an allowance may be made for the difficulties with which I have had to contend.—(Extracts from Report by the Director, Walter Hill.)

POTATOES.—I desire to thank Mr. W. Roberts for his kindness in ascertaining for me the origin of the Ashleaf Kidney Potato.

It was no idle curiosity that induced me to ask you to insert my queries in your valuable Journal, but I am endeavouring to obtain a few facts bearing upon Potato culture for a special purpose; hence I am anxious to know from good authority when Rivers' Royal Ashleaf, Lapstone, and Fox's Seedling were first raised. The last-named I have cultivated for years, and think it by far the best early Potato.—A. FITCH.

KITCHEN GARDEN.

Peas.—A first sowing of Peas may now be made upon a south border, sowing them in drills about 3 feet apart, the seeds being damped and well coated with red lead before sowing them to prevent the attacks of mice. Cover the seeds lightly with soil, and then with sifted ashes about an inch deep, bringing them out to the extent of about 6 inches on the sides of the row. William I. and First and Best are most suitable for this sowing. For growing at the foot of walls Blue Peter, Little Gem, and Premium Gem are suitable varieties. Light warm soils are most suitable for early Peas. If Broad Beans are required very early and a warm border is available, a sowing may be made of Beck's Gem or Early Mazagan in rows about 2 feet apart, treating them in other respects the same as the Peas.

Late-sown Turnips should now be looked over, and those fit for use taken up and stored in damp sand in the root house; this will benefit the remainder of the crop, which may stand for later use. Remove the haulm of Asparagus, and after clearing the plantation of weeds give a good dressing of thoroughly decomposed manure 2 or 3 inches thick, and cover it with a little earth from the spaces between the rows or beds. Remove the decayed leaves from Seakale, and take up any roots that are to be forced inside, and lay them in in a sheltered position so as to be readily obtained when required. That intended to be forced or blanched outdoors should be covered with ashes or cocoa-nut fibre refuse as a protection for the crowns. Globe Artichokes may be cleared of the exhausted stems and decayed leaves, the soil taken out around the crowns 3 or 4 inches deep, a sprinkling of quicklime being given, which will speedily destroy slugs, and the spaces made by the removal of the soil filled with sifted ashes. This is a good protection from slugs and frost.

Forcing Department.—A succession of French Beans should be sown, keeping those previously sown as near to the glass as practicable; earth-up as required, and supply weak liquid manure after the flowers appear, affording a temperature of 60° to 65° at night and 70° to 75° by day; 5° less all round may be allowed when external conditions are unfavourable. A few roots of Rhubarb of some early variety—Johnson's St. Martin's is the best—should be placed in the Mushroom house or other position, with a temperature artificially of 55° to 60°. Seakale may also be planted in rich light soil, and the soil being moist no water need be given until the crowns are moving, then supplying weak liquid manure as necessary. To secure the blanching of the Seakale means must be employed to exclude light. Dung and leaves, two parts of the latter to one of the former, being prepared by throwing them into a heap, turned over once or twice, and damped if necessary. A first bed of Asparagus may be planted, but unless the demand is urgent and continuous and the means adequate little advantage is gained by starting very early. Preparation should, however, be made of the fermenting materials for making up a bed at the end of the month, so as to secure a supply of this most esteemed of forced vegetables by Christmas. Where Potatoes are required early sets of medium size should be placed in boxes and covered with about 2 inches of old tan or leaf soil in a house with gentle heat where the sets will soon have made growth about 4 inches long, when they can be planted in frames or pits with beds of prepared fermenting materials under 6 inches of light rich soil. The Potatoes should be planted, when the soil is warmed, 1 foot asunder in rows 15 inches apart, placing the sets about 4 inches deep. The most suitable varieties for forcing are Early Bird and Veitch's Ashleaf.

Admit air freely to Radishes in frames, and make up another bed, and sow as soon as the heat is up and has warmed the soil, keeping off the lights whenever the temperature is above 35°, with a view to prevent drawing whilst the plants have only their first or seed leaves, but when the rough leaves appear the frame may be kept close to advance the growth.

FRUIT HOUSES.

Vines.—Where it is necessary to have new ripe Grapes in April starting the Vines must not be any longer delayed. If in pots, a good supply of fermenting materials for affording heat to the roots should be provided of a description that will afford a mild lasting heat, such as that obtained by an admixture of two parts of Oak or Beech leaves to one of stable dung. The heat around the pots must not be allowed to exceed 75°, the supply of water being moderate in the early stages. Bottom heat is not essential, but it will hasten them considerably, and if the roots be allowed the run of the fermenting materials the swelling of the fruit is enhanced. Permanent Vines are, however, by many, and rightly, preferred, as they afford finer Grapes with less labour. In that case the early Vines to afford Grapes at the time stated should now be started, the inside border receiving a thorough soaking with liquid manure at a temperature of 90°; making up a bed in the house about 2 feet thick of two parts leaves and one part stable dung, occasionally turning the whole or a part of it over. The moist ammonia-charged heat will greatly facilitate the starting, and be more beneficial to the Vines than fire heat alone. Syringe in bright weather three times a day, damping available surfaces morning and afternoon in dull weather, maintaining a night temperature of 50° to 55°, and 60° to 65° by day, continuing these until the buds burst, then advance 5° all round. The outside border must have regular attention as to coverings from heavy cold rains. Do not delay, as is often done, the pruning of the Vines in succession houses for a considerable time after the leaves have fallen, but push on the pruning and cleansing of the houses and Vines as fast as possible, so as to induce early and complete rest. Remove all leaves from Vines going to rest, and keep the house cool, dry, and airy, also removing the dead and decayed foliage from Vines with ripe Grapes, as they engender moisture, which injuriously affects the keeping of the crop. Late-planted Vines not yet brown and hard in the wood should have fire heat still applied with free ventilation, so as to thoroughly ripen them. Examine ripe Grapes frequently for decayed berries, maintaining a dry cool atmosphere, and protecting outside borders with dry litter or fern with shutters or tarpaulin. Late Grapes should not be cut for bottling until the close of the year or early in the coming year.

ORCHARD HOUSE.

Those who have not potted or top-dressed the trees whilst they were in leaf, and object to placing them outdoors after the leaves have fallen or the wood is ripened, should lose no time in attending to those operations, which we consider preferably performed at an earlier stage. Trees planted out must be examined, and where necessary be carefully lifted, root-pruned, and immediately replanted, removing a portion of the old effete soil, and employing a like portion of fresh turfy loam, firming the soil well about the roots and giving a good watering after replanting, and when the soil has become moderately dry again firm it well and mulch with half-decayed manure about 2 inches thick. Trees in pots not requiring shifting into larger pots should have the soil scooped out at the sides to as great a depth as possible, filling in with fresh compost—turfy loam of a heavy nature, adding about a fourth of well-decayed manure and about 15 per cent. of bone meal, which being in proper condition, neither too wet nor too dry, should be rammed down as firmly as possible, the trees then being given a good watering. Young trees in comparatively small pots may now be shifted into larger pots, which must be well drained, and the sides of the balls being loosened the fresh compost should be rammed as firmly around the balls as possible. Pruning may be done now; but if summer pruning has been properly attended to, and thinning out exhausted growths after fruiting, there will be little necessity for it at this time of year. The only pruning further required will be the thinning of the crowded spurs and shoots in spring, especially those too weakly for the production of fine fruits. To prevent insect attacks dress the trees with

an insecticide, such as a solution of nicotine soap, at the rate of 6 ozs. to the gallon of rain water, applied at a temperature of 90°, which destroys every kind of insect. The trees may be placed close together and covered with some dry litter or fern as a protection for the roots during frost. At all times, except during the prevalence of frost, the ventilators must be left open, the object being to secure a complete rest to the trees, which is best done outside, as by keeping them close and comparatively warm the buds will be excited and cause much trouble to retard the bloom in spring.

STRAWBERRIES IN POTS.

Those plants intended for early forcing must be conveyed under cover as soon as possible. They may be plunged in ashes to the rim of the pots in cold pits or frames, and the lights only employed to throw off heavy rains and to afford protection in severe weather. The plants will not perhaps require any water; but on no account must they be permitted to lack moisture at the roots, or they will lose the young white rootlets so essential to the well-being of the plants in the early stages of forcing. The general stock will do very well plunged in ashes in a sheltered situation, and if a little dry litter or fern be placed over them in severe weather nothing more in the shape of protection is necessary. It must, however, be removed in mild weather, or when there is no frost, for Strawberries like plenty of air and a moist soil.

FLOWER GARDEN.

The frosts and stormy weather have settled matters in a decided manner with the summer and, indeed, autumn-flowering plants of the flower garden. A general clearance will have been, or must be at once effected; and whether it be intended to fill the beds and borders with dwarf evergreens and Conifers of a hardy character, or with other plants for spring flowering, no time should be lost in planting to enable them to obtain hold of the soil before severe weather commences. The plants employed for spring gardening have much to recommend them, as they are hardy and not expensive; indeed a moderate expenditure in bulbs, such as Hyacinths, Narcissuses, Tulips, Crocuses, Anemones, &c., and a few packets of seeds of Nemophilas, Silenes, Limnanthes, Myosotises, and other hardy annuals, with Hepaticas, Snowdrops, Winter Aconites, Primroses, Polyanthus, Auriculas, double Daisies, Violas, Pansies, and Wallflowers, afford a good and cheap display to enliven what would otherwise be cheerless beds and borders. Before digging the beds preparatory to planting the above it may be necessary to give a good dressing of manure, and after planting a mulching of cocoa-nut fibre refuse over the bulbs and about the plants 2 inches thick will improve the appearance.

Such weeds as Plantain, Daisies, and Buttercups on lawns should be removed as opportunity offers in mild weather during the winter. The removal of these will encourage the growth of the grasses and do much towards securing a rich velvety lawn. The heavy rains have brought worms to the surface, disfiguring the lawn. Give them a dose of lime water, which soon brings them out, and they may be swept up and destroyed. A few applications of this will save much time in sweeping and rolling. Any inequalities in the lawn surface should now be rectified by raising the turf, filling in the low parts before relaying the turf, whilst those too high should have soil taken out and the turf lowered, beating it well down.

Herbaceous borders have a wintry aspect—little in flower, many plants that are usually fine at this season being cut by frost. The tops of any varieties that are sufficiently ripened should be cut off, and the surface of the soil made neat and clean by stirring. Remove the soil from about the crowns of Pyrethrums, and Delphiniums which are liable to have the crown buds eaten by slugs, and after dusting with quicklime fill in with sifted ashes. Take up Dahlia roots, and after laying a few days to dry in a shed store away in sand in a place safe from frost. Take up and pot choice Hollyhocks, and winter them in a cold frame.

PLANT HOUSES.

Orchids.—Lowering the temperature gradually will have induced partial rest of the Orchids in the East India house, but moisture must nevertheless be attended to as soon as the temperature commences rising in the morning, or by 9 o'clock. Water will need to be sprinkled or poured over the paths, and to any plants requiring it water should

be supplied sufficiently to keep the moss damp. The watering and syringing must be done by twelve o'clock, which will allow of the house becoming dry by the time the temperature lowers, which is of importance, as a cold wet atmosphere is inimical to the health of the plants; ventilation will only be necessary on fine days to prevent the temperature rising too high. Any plants of *Dendrobium nobile* that have completed their growth and are swelling their buds may be placed in the East India house and damped overhead on fine days, and they will be in flower by the new year. Cattleyas and *Dendrobiums* should receive very little water at their roots, and any blocks or newly imported roots will need damping occasionally. Let all plants coming into flower be thoroughly exposed to the light, or they are liable to lose the buds at this season. Plants of *Laelia purpurata* which have not completed the growth should be kept in the warmest part of the house. *Calanthe vestita* and *C. Veitchii* coming into flower should have very little water and the atmospheric moisture not excessive, or they will cast the buds and the flowers be spotted, therefore keep the plants fully exposed in the driest part of the house. *Lycaste Skinneri*, though a water-loving plant, requires less at this season, but the roots must not be allowed to become too dry or the pseudo-bulbs speedily shrivel. The water should be kept from the base of the pseudo-bulbs, or the flower buds will decay when about an inch long. *Cypripediums* must be well supplied with water, they not requiring any rest. Many of the *Odontoglossums* and *Masdevallias* will still be growing freely, and must be kept moist at the roots; and although these plants require plenty of water, care should be taken at this dull season not to have a saturated atmosphere.

TRADE CATALOGUES RECEIVED.

Bruant, Boulevard Saint Cyprian, Poitiers (Vienne-France).—*List of New Begonias*.
Edward Phillip Dixon, Hull.—*Catalogue of Roses, Trees, and Shrubs*.
John Carter, Keighley, Yorkshire.—*Catalogue of Nursery Stock*.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Address (*Robert Thorburn*).—The address you require is Mr. J. G. Wagstaff, Albert Ironworks, Dukinfield, Ashton-under-Lyne.

Dividing Pyrethrums (*G. O. S.*).—Spring is the best time for dividing these plants, just as they are commencing fresh growth. It is advisable to remove some of the soil from around the plants now and place some ashes round them, which will enable the water to pass away freely and destroy the harbour for slugs.

Magnum Bonum Potatoes (*J. Renshaw*).—Your crop was good, but the records of greater productiveness have been sent to us. The good cropping qualities of this variety are so fully and generally admitted that it is not necessary to publish the weights of crops of little more than the ordinary character.

Bedding Pelargoniums in Hyde Park (*Harebell*).—The following are amongst the most effective varieties employed in this Park:—Miss M. Holden, scarlet; John Gibbons, scarlet; Letty Carr, crimson; Sir H. Stanhope, dark scarlet; Col. Wright, salmon scarlet; Wordsworth, bright scarlet; Lucy, pink. Mrs. Turner, bright pink; Rose of Allaudale, a bright shade of pink; and Theocritus, rich scarlet. At the Crystal Palace Lady Constance Grosvenor is largely employed as a scarlet, as also is Vesuvius, Cleopatra being the leading pink variety planted there. Silver variegated—Albion's Cliffs, Miss Kingsbury, Princess Alexandra. Yellow-foliaged Varieties—Robert Fish and Crystal Palace Gem.

Zonal Pelargoniums for Pots (*Idem*).—Mrs. Windsor, blush white; Joyful, pale magenta; Mrs. Davidson, deep rose; Samuel Plimsoil, purplish crimson; Henry Jacoby, dark crimson; President Gambetta, reddish salmon; Rebecca, rose crimson; Clemence Boutard, blush; Louis, magenta; Charles Schwind, crimson; T. Schuler, bright scarlet; and Fanny Cattlin, rosy salmon. These are all single varieties, which we presume you require, and with good cultivation produce very large trusses. The address you require is T. W. Cowan, Esq., Horsbam, Sussex.

Guernsey and Belladonna Lilies (*J. P.*).—You no doubt potted the bulbs too deeply and watered them too freely. In all probability several of them, if not all, are dead, at least all that do not emit roots are worthless. Those that produce roots may eventually be planted out in a warm position. They will not be suitable for forcing next year, and do not like being disturbed too frequently. If you send 3½d. in post stamps to the publisher and ask him to send you No. 752 of the Journal, you will find some cultural notes on these plants.

Tea Roses for Forcing (*Idem*).—Your plants would have been better placed under glass before they made their second growth. Without knowing their condition more precisely it is not easy to advise you; but probably if you prune them just below the base of the second growths and train the firm portions of the shoots round stakes, they will eventually produce flowers freely under careful management. They must have abundance of light and not too much heat at the first; a temperature of 45° to 50° will be sufficient until they are growing freely, and they should not be started before January if you want good blooms.

Rabbits v. Fruit Trees (*P. G.*).—The most effectual plan of preventing injury to the trees is to encircle the stems loosely with closely made galvanised wire. Less permanent modes of preserving the bark is to tie old bark from other trees round the stems, or briars may be employed. Stout brown paper secured round the trees and thickly smeared with tar lasts for a considerable time. A mixture of sulphur, lime, and cowdung thickly smeared on the stems only lasts for a short time; to be effectual such dressings must be applied twice during the winter. If you secure anything of a permanent character round the trees you must examine the ligatures frequently and loosen them when necessary. Plant the exposed side of your orchards with the Dumelow's Seedling Apple; it is hardy and of rather close growth.

Climbers for Exposed Situation (*Alex. F. Roberts*).—We have seen the following plants upon the south front of a house 540 feet above sea level, exposed to the force of the south-west wind coming over at least 30 miles direct line of moor—*Clematis Vitalba* or Traveller's Joy, *Caprifolium Periclymenum* (Honeysuckle), *Jasminum officinale* (Sweet White Jasmine), and Ayrshire Roses—viz., Dundee Rambler, Splendens, and Ruga; those would probably succeed with you. Most varieties of Roses, Clematises, and other climbers or wall plants were tried in the same position and failed.

Substitute for Pampas Grass (*Idem*).—*Erianthus Ravennæ* would probably succeed where Pampas Grass has failed; but though a fine grass, is not nearly so effective as Pampas Grass, which might thrive if you afford it protection in winter.

Adiantum farleyense Unhealthy (*Constant Subscriber, Liverpool*).—Assuming that the temperature of the house is suitable for the Fern we consider the soil in which your plant is potted is unsuitable. We should remove all the decaying fronds now, and when fresh growth commences in the spring remove a good portion of the soil and repot the plant in fresh compost, and in a smaller pot if possible. Turfy loam and peat with a liberal admixture of charcoal will induce healthy root-action; the plant should then be shifted, employing a richer compost. The finest plants we have ever seen were growing in a compost of two-thirds of strong loam that had been previously submitted to the action of fire, and one-third part of the remains of an old Mushroom bed, with charcoal and wood ashes to keep the soil porous and sweet.

Potatoes (*E. Yorke*).—It is about as impossible to determine the varieties of some Potatoes by merely seeing the tubers as it is to determine the names of certain Peas by inspecting the seeds. The tubers you have sent are very small, you do not even say whether the variety is an early one or not. We will have them planted, and possibly we may be able to recognise the variety after seeing its growth and comparing it with others.

Lichens on Trees (*A. J. Z.*).—The land probably requires draining, and even this is not effectual in some districts for destroying lichens on trees. When the branches are quite wet and there is little or no wind, as during a fog or just afterwards, freshly slaked lime should be thrown plentifully through the trees, and it will adhere firmly, leaving them quite white. This will destroy the lichens, and the lime that falls to the ground will be beneficial. We have cleansed many trees by this process, but success depends on the manner in which the work is done. The lime must be used liberally, and where the trees are large the operator must have the use of a ladder. Young trees can be dressed with lime in the form of thick whitewash applied with a soft brush.

Fruit Trees not Bearing (*H. T. H.*).—We can scarcely understand the condition of your pyramid trees which are growing "most luxuriantly," yet "bristling with fruit buds." When young trees grow very strongly they do not usually produce fruit buds freely. If your trees blossom profusely and yet no fruit follows, we can only attribute the failure to the effects of frost in spring or to immature wood. The spurs of Pear trees are also occasionally injured during the winter when the frost is very severe and the mercury of the thermometer approaches zero. We can only suggest that you cut off any roots that penetrate the clay, and encourage by manurial top-dressings fibrous roots near the surface of the soil, and at the same time remove some of the branches of the trees that are too closely together, so that the sun and air can act beneficially in maturing the growth. The Jargonelle trees you no doubt root-pruned injudiciously. You must now by the application of fresh soil and surface mulching with manure induce healthy root-action; this with judicious pruning will aid in the restoration of the trees.

Sulphuric Acid v. Plantains on Lawns (*Shillingstone*).—We do not dilute the acid at all for this purpose. Our plan is to place it in a strong stone bottle, such as an old blacking bottle, with wire twisted round the neck so as to form a handle. It is applied to the Plantains with a stick a foot long and of the thickness of an ordinary pencil, several notches being cut round the end for an inch or two. When placed in the acid sufficient is held in the notches for killing two or three of the weeds when they are close together and can be "doctored" quickly. One drop quite in the centre of each plant will destroy it. We have tried it on Dandelions and Thistles as well as Plantains, and have found on digging up the roots a short time afterwards that they have been burnt for a considerable depth; in fact we have never found the acid fail in killing all kinds of weeds on lawns to which it has been properly applied. With a little practice a man (for the work should not be entrusted to women and boys) soon becomes expert in applying the acid, and a large portion of lawn is soon rendered free from these unsightly weeds. The stick must not be rubbed on the grass, as it leaves brown marks wherever that is done, as it frequently is by those using the acid the first time.

Arsenic for Destroying Weeds on Walks (*Idem*).—Dissolve 1 lb. of powdered arsenic in 3 gallons of cold water and boil it, stirring it well when on the fire; then add 7 gallons of water holding in solution 2 lbs. of soda; boil and stir again, applying it when hot to the walks through the rose of a watering pot, taking especial care to protect the grass or other edging with boards, or the

poisonous liquid will do much damage. The quantity named is sufficient for 25 square yards.

Making a Propagating Case (*Idem*).—You can make an excellent propagating case by enclosing a portion of the hot-water pipes. The best plan would be to have a shallow tank 2 inches deep to form the base of the bed, a trough from the tank protruding through the wall to show the depth of water in the tray, and for replenishing when needful. The tray should stand on the pipes and be perfectly firm and level. It should be covered with slates, on which can be placed 6 inches in depth of cocoa-nut fibre refuse. Bricks on edge will be suitable for enclosing the pipes, but stout deal boards last for a considerable time. The space should be covered with a well-fitting yet easily removable glazed frame light placed at sufficient height above the plunging material to accommodate the cuttings you desire to strike. In a well-managed propagating case of this kind hundreds of cuttings can be struck and seedlings raised during the spring and summer months.

Renovating Old Pear Trees (*Young Gardener*).—We presume that the trees produce an abundance of growth each summer, but form no fruit spurs. Root-pruning will not render such trees fruitful; yet if their growth is very luxuriant you might remove the soil from the roots and sever any that take a directly downward direction. The fact that fruit is produced on the extremities of the branches of the trees on walls suggests a remedy. With a saw remove the fruitless spurs close to the main branches, paring the "cuts" smoothly with a sharp knife. If the branches are covered with moss it will be well to dress them with freshly slaked lime, the colour of which can be toned down with soot if required. This will cleanse the bark. In the spring fresh growth will be produced in clusters all along the stems; this must be thinned out by rubbing off a great number of the shoots, not cutting them, eventually retaining only those that are short-jointed and placed 2 or 3 feet apart. These should be tied down to the main stems, and if they are not shortened they will in due time produce fruit spurs precisely in the manner of the extremities of the branches. The exact distance for leaving these young growths can only be determined by their character. If the growths are very luxuriant they may be bent and trained backwards along the main branches—that is, with their points directed to the trunk of the tree, but if only of moderate strength this is not necessary. By adopting this practice you will have no fruit for two years; but after that time fruit will in all probability be produced freely over the entire surface of the wall, and with judicious pruning the trees will continue fruitful for a considerable time. We have proved the value of this method of rendering old Pears fruitful, but it is only applicable to trees that are healthy and free from gum and canker.

Names of Plants (*A Constant Reader*).—6, *Cratægus coccinea*; 7, *Rhododendron Wilsoni*; 8, *Picea cephalonica*; 9, *Taxus baccata adpressa*; 10, *Sequoia sempervirens*. (*Aske*).—The specimens are so small and unsatisfactory that it is impossible for anyone to name them with confidence. No. 5 appears to be *Retinospora plumosa*, and 1 and 3 are probably varieties of that species; 2, *Jupinerus chinensis albo-variegata*; 4, *Retinospora plumosa aurea*; 6, *Thuja Lobbiana compacta*; 7, *Retinospora obtusa*. (*G. O. S.*).—*Berberis vulgaris* var. *nigra*. (*C. F.*).—1, *Dendrobium Gibsoni*; 2, *Cyanophyllum magnificum*. (*William Gorrie*).—*Satureia montana* or Mountain Savory, a native of mountains in the south of Europe. It has been long known in this country, having been introduced about the middle of the sixteenth century.

POULTRY, PIGEON, AND BEE CHRONICLE.

BREEDS OF CATTLE ADAPTED FOR DAIRY FARMING.

THE fifth annual Dairy Show, which opened at the Agricultural Hall, London, on the 26th of October last, proved a successful meeting, and as a whole was highly suggestive in various ways. It not only served to inform the public of the breeds of cattle kept for dairy purposes, but it exhibited the machinery and the methods whereby milk is converted into cheese and butter. It also opens an inquiry as to how and in what proportion different breeds of cattle contribute towards the production of these articles. The owners of cattle, too, are enabled to obtain information relating to all the details of breeding, rearing, feeding, &c., whereby they may attain success in dairy farming, which is now becoming the most important business connected with the occupation of pastoral districts throughout the kingdom. In the consideration of our subject we will discuss the advantages of the varieties of cattle as they were placed on the prize list at the Dairy Show.

Shorthorns take the leading position, and are justly considered the most important dairy stock now to be found in this or any other country. In order, however, to enable them to maintain this high position the greatest care, vigilance and almost hourly attention, are requisite, backed by the most experienced, judicious, and intelligent management in all the details of breeding, feeding, and housing, together with the manipulation and manufac-

ture of the products in milk to the best advantage of which industrious people are capable. We must, however, call attention to the difference in breeding cattle for the dairy as compared with those to be reared and fed for the butcher, the latter object being often in the ascendant. This is especially the case when we engage to rear all our animals within certain lines—namely, by pedigree, for it frequently happens that breeders in their endeavours to keep to pedigree make dairying capacity a secondary object. They concentrate all their knowledge and perseverance on one object—that of producing animals of a fashionable colour, and possessing what is called quality and correct outline, together with wide, deep, and long form of the body, being perfectly satisfied if the cows will rear a calf only without assistance from artificial feeding. Now, we need scarcely point out that this mode of proceeding is directly opposite to that required in the breeding of cattle for yielding dairy produce. Although it is highly desirable to breed cows which possess the double advantage of being great feeders as well as deep milkers it is very seldom attained, as it requires the most judicious selection and mating. When success has attended the efforts of some celebrated breeders they have attained their object entirely from the selection of exceptional animals, and by unusual endeavours have succeeded in converting the produce into a high-class breed. At the same time, however, our own experience teaches us that it is far easier to obtain a high class of stock than it is to maintain them as such. The reason of this we have found in the fact of the best milkers being often imperfectly formed as regards the forequarters, because as a rule those cows which are wide over the heart with heavy forequarters are seldom good milkers, hence the difficulty of combining heavy flesh and correct shape with deep milking capacity in the same animal. These are matters of so much importance in the breeding of dairy stock that we have—in the interest of the home farmer, and particularly the young men, so many of whom are yearly entering on dairy management—dwelt upon the subject at greater length than some experienced men may consider requisite. As we are now referring only to rearing cattle for dairy purposes it should be understood that for several reasons we advise moderate feeding at periods when the animals are not yielding milk, because they are likely to be more healthy as young stock, more likely to breed early and more regularly after bringing their first calf, and during the time cows are out of milk they are not so likely to accumulate fat internally, which is frequently the cause of the drop or downfall in the udder after calving.

In selecting animals for breeding both sire and dam should be certified as being saved from good milking stock, and this is of the highest importance, whether breeding from pedigree stock or ordinary Shorthorns. The time which the cows or heifers should calve is usually regulated by the requirements of the produce. If the making of cheese and butter is the object the calves should drop about February or March, so that they may be removed by the time the grass is ready for feeding. With respect to heifers, they should bring their first calf in April or May. Calves reared to make good any losses in the dairy by cows becoming barren, &c., should be weaned early, and kept well enough to maintain them in health and in a growing state. The first food should be new milk for about two or three weeks, then skim milk, or some of the various substitutes which will keep up their condition. After going out to graze they should have shelter at night, or lie on a very dry sheltered paddock, and be offered hay and a little cotton cake. The only fear of disease is from the scour or quarter ill, and the treatment we have stated is likely to avoid these complaints. There is much controversy as to the age the heifers should drop their first calf; we incline to and believe the balance of opinion of the best dairymen is that they should not breed until they are from twenty-six to twenty-eight months old.

Having been carefully managed and moderately fed up to that age the heifers may, in the interest of their future value, suckle their own calves, and several others in succession for making veal, and nearly up to the time when they are due to calve again. With the greatest care in hand-milking it is certainly not like the calf sucking, nor will the animals continue to yield milk either so much or for so long a time in any way as by suckling calves. When we consider the effect of this in the future profit of a cow, especially as to the length of the milking period, it is of more importance than many dairymen admit, simply because it is not fashionable amongst their craft to continue milking the cows until they begin to spring for the next calving time. This leads to one of the most important points in the whole range and detail of dairy farming, for after being allowed to become dry for several months before the cows bring the second calf they will often do so again in the future, in spite of the most careful management. There is, however, a strong feeling of prejudice in the minds of many otherwise practical and experienced men that it is advisable that the cows should go dry for two months at least before producing another calf. We are, however, justified by our own experience in opposing this practice, because whilst the well-bred Shorthorned cow is out of milk she is sure to make fat internally, and this is the cause of the most serious malady to which they are subject ("puerperal fever") at the time of calving. It is held, however, by the advocates of the vacant period that the cow gives more milk after calving in consequence. But we do not admit this; and even if we could reasonably do so there would still be the fact in favour of the extended milking period, to say nothing as to the danger of losing some of the most valuable cows in the herd, as it is what we call the best doers which are most likely to suffer.

We must now refer to the daily life of the cows in the pastures. First of all kind treatment, which will always keep the animals in a docile and quiet state, is of much importance, as well as good and fresh pasturage, and this should be constantly changed. The herds for daily management should be not more than from twenty to thirty in number, in order that they may have the advantage of more change, for although each portion of the herd may succeed the other daily on the same pasture it is preferable to a large number feeding together without the change. It is also a matter of great consequence that only a moderate number be herded together, for we have known serious injury occur to the cows when large numbers are hurried through a common gateway.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Wheat land preparation, manuring, and seeding will continue to employ the horses for some time yet, as in consequence of the changeable weather which has lately prevailed some delay on almost all soils has occurred. Still, where there is Clover lea to be ploughed, this work can be continued when the fallows or ploughed surfaces cannot be worked with advantage. Upon light dry hill land the ploughing after roots fed off by sheep should be very shallow—just deep enough that all the surface soil may be turned over; a depth of 3 inches will suffice in that case, and the presser following the ploughs, the land will then be left in a fitting state to be sown broadcast immediately behind the ploughs. Under the circumstances is better than drilling, for the seed will fall into grooves formed by the presser, and will be effectually buried by about two times with the iron harrow. It will also find a firm bottom for the young plants to root in, so essential to their healthy growth, which they do not always obtain when the land has been worked down before drilling. The home farmer will understand that by sowing after the presser the plants will stand in lines not quite so regular as when drilled, but quite regular enough for horse-hoeing in the spring. The lines will stand about 10 or 12 inches apart, and in horse-hoeing a few plants would be destroyed, yet leaving quite enough to maintain a good plant at harvest. We wish, however, to call attention to another plan of sowing Wheat, especially in November or December, for the weather which usually prevails in these months in our climate is an alternation of rain and night frosts, which often impede the sowing upon land that has been ploughed some time previously. Upon light free-working land after roots have been fed off it is a good plan to sow the Wheat broadcast and plough it in with a fleet furrow, which after being harrowed down the Wheat seed will not only be thoroughly buried but will find a firm holding for the plants at the bottom of the furrow. The distance we have named for lines of Wheat may by some farmers be thought too wide for light land, but it must be remembered that such soils are generally subject to weeds like the Poppy, Charlock, &c., which injure the Wheat most seriously unless destroyed by horse or hand hoeing. Upon the best-managed hill light land farms we have seen all the cereal crops have been drilled at 12 inches apart. As the season advances we prefer to sow red Wheats, such as the Golden Drop and the nursery varieties, as they are more hardy and maintain plant better under adverse and winterly weather than the white sorts.

Hand Labour.—As the Wheat sowing approaches conclusion other

work for the men will spring up, such as assisting at the threshing of Barley, fine weather being chosen for the purpose; and if the ricks have been made a moderate size, and such as each may be all threshed during a short winter's day, the straw being also stacked and thatched the following day, and the corn dressed and sacked up in the same way that it is done by one of Clayton & Shuttleworth's best and latest improved machines, it will be then fit for sale off the machine if it is thin Barley fit for the miller only. In case, however, it is almost a malting sample with some thin grains in it the bulk will still pay for careful screening, in order to separate the thin grain for grinding from the best or malting Barley. This will pay well for separating if done with the best and most improved screen. The newly patented Nalder's "Duplex" malt-screening machine is much esteemed by farmers, and is also used by the malsters for cleaning the Barley and taking out the thin grain before malting it which may be found in the sample. It is very useful to the home farmer for separating the grinding from the malting grain, and nothing in the detail of the farmer's business will answer better; because not only will the malting Barley secure the best price if the grain is of good colour and has been well harvested, but he will have the thin grain always required for the feeding of stock for use on the home farm; whereas, if the thin and best Barley had been sold in bulk without separation the whole would have been seriously depreciated in value. It is a good time now to buy young cattle for wintering, and we notice that the Irish importations are of an improved kind lately, being more like the true shorthorned stock, with good long soft hair; and the animals, whether heifers or steers, show a better outline, and as a consequence make more proof in the feeding. The sheep stock, both lambs or tegs and ewes, are coming to market in good condition. The former will pay well for the feeding during winter, and the ewes to lamb from January to March. Farm horses are cheaper, there being so many farm stock sales going on, besides which the statistics show that the stock in the country has increased in numbers lately. A large crop of roots, especially of Swedes and Turnips, is general throughout the country, and in some cases on heavy land they are being passed through Gardner's cutter and spread and ploughed in, but more especially where farmers are short of cash and cannot buy stock to feed the roots on the land or in the cattle boxes. The home farmer, however, should have cash at command for all the requirements of the farm, both in stock and otherwise.

ADVANTAGES OF A HOME FARM.—No. 5.

SHEEP, GRASS, AND HAY.

WHEN the rickyard contains a good stack of Clover hay, two or three substantial ricks of prime new meadow hay, with enough old hay remaining to carry us into the new year, then we are not afraid of a long hard winter, nor are we obliged to sell lean stock at a loss. This year the red Clover was a heavy crop, but the small size of the other ricks bears evidence of the falling-off in the supply of meadow hay. The long duration of dry weather in spring and early summer told upon the grass land with especial severity; the growth was so much below par that many farmers waited fully a month later than usual for the hay harvest, and consequently much hay of inferior quality was made owing to the earlier growth having shed its seed and become sere and white long before it was cut. I am accustomed to reserve 40 acres of grass for hay, and pay particular attention to certain cultural rules which experience has shown may not be infringed with impunity. No sheep are allowed to feed upon it after February, for late feeding in March undoubtedly does much injury to the hay crop. Romney Marsh sheep do not thrive upon the low-lying, cold, wet land of their native marshes in Kent during winter; they are therefore driven to the uplands at Michaelmas, and then large flocks of them come into hilly Sussex to be distributed in pre-arranged numbers among many of the farmers, with whom they remain till Lady-day. Now as this falls on March 25th they are apt to prove a source of loss during the last two or three weeks of their stay, "eating the heart out of the grass" to its serious detriment for hay, and it would be a nice calculation to decide how much actual profit is derived from the 10s. or 12s. per head that is received for the six-months "keep." The soil is so thin and poor that unless the grass land reserved for hay has an annual dressing of manure it deteriorates so much that about half a crop is the result even with the most favourable weather. The application of manure to the whole of it in March is therefore never omitted; no dung mixen is used for this purpose till it is thoroughly decayed. Spread as it is carted on the land, it is at once worked well in with a bush harrow; any stray stones are picked off, and as soon as it is dry enough it is rolled. We generally contrive to spare enough farmyard manure for 30 acres, and the remaining ten have artificial manure, which is also applied early in March. It is a moot point which kind of manure is soonest exhausted or rather absorbed into the plant's system. The fact of the prepared artificial manure powder being most soluble has probably given rise to the popular opinion that the benefit derived from it, though undoubtedly great, is in

comparison with farmyard manure brief in its duration. I have watched the effects of both classes of manure closely, and have found it so evenly balanced as to induce me to place both upon a par as valuable fertilisers.

This result is of the utmost importance to those of us who carry on farming in a hilly country at a considerable distance from a railway station. Mr. Lawes, a high authority upon questions of manure, uses 14 tons per acre of farmyard manure upon his land. Now I cannot procure manure of that class in this neighbourhood, and if I turn my attention to London dung, of which there is plenty in the market, the lowest price is 9s. 6d. per ton at a railway station five miles off; add to this 5s. cost of cartage per ton to the farm, and we have the startling total of £10 3s. per acre for manure. Gladly, therefore, do we turn to the artificial manure which is delivered at the same railway station at £8 10s. per ton for quantities of not less than 2 tons. It is applied to the land at the rate of 4 cwt. per acre, and the total cost including cartage and labour may fairly be stated at 36s. per acre—a reasonable rate of expenditure, for which the land in all favourable seasons as to weather yields a fair return, not only in its ton or more of hay per acre, but in that after growth so valuable for the dairy cows, and which alone is sufficient for their maintenance during August, September, and October.

Haymaking is such an important operation that it must be reserved for consideration at an appropriate time.—EDWARD LUCKHURST.

MALTING BARLEY FOR CATTLE FEEDING.

As the time is near when farmers will be malting Barley for cattle, we have asked a scientific maltster of many years' practical experience to give us a few plain hints for publication; the following are his remarks:—

PLANT.—I should advise farmers to be very cautious in buying or building the various things required for malting. Bad as some Barley may be, it may still pay for proper treatment, and for this purpose some little care and knowledge are required. It is not improbable, therefore, that some of the small country malt-houses, now but little or at all used, may under the new system be put to work for this purpose. A farmer may probably find it better to send his Barley to one of these places and pay 2s. or 3s. a quarter to have his malt properly made. Perhaps one large farmer, or a combination of smaller ones, may find it pay to hire one of these buildings than to have all the trouble and expense of erecting them. In the process of working, too, the grain must be attended to at the right time whatever else may be in hand, and it may not improbably be found inconvenient and expensive to take a labourer three or four times a day from his regular employment to look after a few sacks of malt. Those who decide to give the new plan a trial on their own premises might begin with a few tubs for wetting, a level floor of almost any sort for working, and a bit of hair-cloth or wire, enclosed, with an opening into an existing chimney for drying. In making the kiln it will be well to forget all the traditions of malting—as it will in some other respects also—for when malt is made for beer, *flavour* that can be developed by heat is an important consideration, while that for cattle need only be dried at “sun heat,”—say, beginning at 70° and not exceeding 130°. It is very probable, too, that our manufacturers will soon be offering a cheap handy small kiln for this purpose.

Steeping.—Under the excise laws the maltster was limited as to steeping and sprinkling the growing malt, so it is as well to forget the usual fifty hours, and let the Barley lie under water for a time, varying with the weather and the quality of the corn. In winter, and with stout flinty grain, seventy or eighty hours would not be too long.

Working.—When the water is drawn off the corn may remain in the steeping vessel for a day, or till it acquires a slight warmth—say not exceeding 60°. It may then be turned out on the floor at such a thickness as will keep it about this temperature and bring out a short bushy root. To keep this root short, strong, and healthy—not dried or shrivelled—is the object to be attained, and the growing corn must be stirred, turned, and sprinkled as often as may be found necessary to secure this. Especially must it be remembered that in no case should it be allowed to heat or “get together,” for in that case an unpleasant flavour will be produced and a loss of quality sustained.

Drying.—After lying from eight to seventeen days on the floor, according to weather, &c., the acrospire should be at least half-way up the back, the interior of the grain all flour, and should make a mark like chalk on the finger nail. The water should be all out of it, and it should now be put on the kiln, turned occasionally, and dried sufficiently for keeping.

I think there will be no necessity for screening, as the whole—

root and all—may be ground up together. It may be well to add that the process should take place in cool weather, and with Barley fresh from the straw; and, further, that under certain circumstances other grain may pay for malting better than Barley. It is quite out of my province to say a word as to feeding, still it may not be amiss to caution beginners that it will most probably be found that malt alone will not be so profitably used as when mixed judiciously with other food.—(*Land Agents' Record*.)

THE CRYSTAL PALACE POULTRY SHOW.

THE schedule of this great Show reached us somewhat late. There is always but a short interval between its publication and the close of entries; we suppose that its great prestige warrants this. The Dorking and Cochin classes are much the same as in former years. Langshans and Black Cochins are classified together! There are no less than seven prizes for Dark Brahma cockerels, the first being £15 15s.; for Dark pullets there are six prizes, the first being six guineas. Light cockerels and pullets each have a first prize of the same amount. There is a class for La Flèche, two for Plymouth Rocks, two for Andalusians, two for Sultans. Japanese Bantams again have a class to themselves. Ducks seem liberally treated with no less than nine classes. There are again two classes for respectively the heaviest cockerel and the heaviest pullet, but this year with the proviso of their being “suitable for the table.” There is also another class for the best couple of cross-bred cockerels or couple of pullets (not capons), in which “fineness of quality, smallness of bone, absence of offal, and closeness of plumage is to be considered in preference to mere weight; sex and breed of parents must be stated.” Among the poultry Judges we see the names, now, we think, at the Crystal Palace, of Mr. T. C. Burnell, Mr. S. Matthew, and Mr. T. Raines.

For Pigeons there are ten classes for Pouters and one for Pigmy Pouters, a champion class and twelve other classes for Carriers, twenty-one for Dragoons—which embrace almost every age and colour—six for Tumblers, three for Fantails, seven for Jacobins, eight for Owls, seven for Turbits. Frillbacks for the first time have a class to themselves, and Magpies now have three.

If there are among our readers any who love poultry and Pigeons and have not seen the Palace Show we advise them to make an effort to attend it this year. The place is unequalled for such an exhibition.

FOWLS AND THE COLD WEATHER.

THOSE who have given much attention to fowls can pretty well tell what cold different varieties will enjoy throughout the winter without being injured, but others with less experience are often seriously alarmed on the approach of winter as to how their favourites will bear it. When a new breed has been taken in hand their hardy and tender points have to be ascertained, and practical hands soon learn this; but beginners are not so quick, and are more careful—in fact, they are, as a rule, too careful. Fowls which have been coddled and pampered in fine weather will never endure cold well or severe weather, but those which have been brought up in an ordinary hardy way will scarcely feel the change of weather; indeed, many fowls seem to enjoy better health in cold weather than they did in the hot season. Cold certainly sharpens their appetite, and this itself is an advantage when they are to be fattened for killing, or backward pullets for laying. Since the weather began growing cold our fowls have eaten more food than they did before. They are also redder in the combs, and have more spirit. Very hardy breeds of fowls, or those which have been used to it, will sleep out on the trees and bushes all night for the whole of the winter, and never appear in the slightest way harmed. Wet is more injurious than cold, and the two combined are worse still. The most tender fowls will bear much cold, but wet soon generates disease. We should have no hesitation whatever in allowing the most tender fowls to have a long and good run out on a sharp dry frosty day, but we prefer keeping them inside or under cover when it is raining or snowing. This particularly applies to crested fowls, as when the crest becomes wet it is a long time in drying in cold weather, and they are very liable to have as the result a severe cold in the head. Those with wired runs and covered houses can easily give their fowls whatever treatment they like in the way of letting them out or keeping them in; but many have not the convenience, and the best advice that can be given to such is to allow their fowls freedom in dry weather and keep them under cover as much as possible during wet. They had better be crowded together in their roosting houses or sheds for a day or two than be allowed to become thoroughly drenched. With an ordinary amount of care in this way no one need be afraid of their fowls being injured by

the cold in winter—at least, I have never experienced anything of the kind, and I have kept some of the most tender breeds. But it is not always those that look most tender that really are so. Most people who see our Sultans exclaim, "What tender fowls they must be!" but it is quite the reverse, as I know of no variety of fowl so hardy.

Careful feeding is a great assistance to all fowls in cold weather. Much that benefits them in summer should not be given to them in winter. Warm food in the morning is suitable; barleymeal is our morning feed throughout the winter. It is mixed with water as hot as the hand can bear, and given to them at once. The last feed at night is grain. They do not become hungry again on this so quickly as on soft food. In very cold weather I generally place the grain in a tin dish, pour a little water or beer over it, and place it in an oven until it is warm, and let them have it in this state. This has a tendency to keep them comfortable during the night, and it also increases the supply of eggs, which are very liable to become scarce in cold weather.—J. MUIR, *Margam*.

VARIETIES.

WE understand that a general meeting of the Poultry Club will be held in the Crystal Palace on Tuesday, November 16th.

— SULTANS AT THE DAIRY SHOW.—We were pleased to observe at the Dairy Show last week that our correspondent, Mr. J. Muir, Margam, won the first prize in the Any variety class of fowls with one of the most promising pair of young Sultans we have seen for a long time. Although only six months old they were in splendid plumage, and their faultless colour testified to Mr. Muir's skill in practising what he lately advised in these pages about washing white fowls before sending them to exhibitions.

— EXHIBITING POULTRY.—A successful exhibitor writes as follows:—"As the season of poultry shows is coming on we may give a few hints to beginners, for probably some of your readers who have never before shown poultry will do so at some of the coming autumn exhibitions. Birds caught up suddenly from large fields and woodland runs will not do themselves justice. It is well to keep two or three show pens, which can be purchased from any of the great makers and contractors for such things, and accustom birds to them beforehand. We have known inferior birds from our own yards defeat others, manifestly their superiors at home, from being used to a pen, standing up boldly, and so displaying themselves to advantage. Poultry with white earlobes, such as Hamburgs and Black and White Bantams, are greatly improved in their lobes by confinement for a week or ten days under cover."

— BATH AND WEST OF ENGLAND SOCIETY AND SOUTHERN COUNTIES ASSOCIATION.—At the Council meeting held October 26th, 1880, at the Grand Hotel, Bristol, it was decided, in accordance with a wish expressed by the Tunbridge Wells Local Committee, that the Show of next year be fixed to commence there on Monday, June 6th, and close on Friday, June 10th. The principal alterations in the list of prizes had been the addition of a class for agricultural yearling colts, and the increase of the second prize for cart mares. The Committee of the Sussex Herd Book Society having offered to add third prizes to all the classes for Sussex cattle in the Society's list, the offer was accepted by the Council with thanks. The fees for the entry of horses were decreased, and will in future be 20s. for each entry for members of the Society, and 30s. for non-members. It was also decided to receive post entries up to the 1st of May on payment of additional fees—viz., 10s. for each entry for horses, and 2s. 6d. for cattle, sheep, and pigs. Letters from Mr. George Simpson of Wray Park, Reigate, and others were read, requesting the Society, in consideration of the growing importance of the Channel Islands breeds of cattle and their large representation at the exhibitions, to place them in the same position in the prize list as the Shorthorns, Sussex, and other leading breeds. The Council, however, while anxious as far as possible to meet the wishes of so influential a class of exhibitors, regretted their inability to comply with their request in consequence of there being at present no funds available for the purpose. Mr. R. H. Bush presented the draft list of prizes offered for poultry and Pigeons at Tunbridge Wells, which was received and adopted. The list had been considerably improved by the addition of third prizes in all the classes and the lowering of the entry fees.
